(3) As required in § 101.13(j)(2) for relative claims, the identity of the reference food; the percent (or fraction) that the calories, and, if appropriate, the fat, were reduced; and quantitative information comparing the level of calories and, if appropriate, fat content, in the product per labeled serving size, with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim, (e.g., "⅓ fewer calories and 50% less fat than our regular cheese cake: lite cheese cake—200 calories, 4 grams fat; regular cheese cake—300 calories, 8 grams fat per serving").

(c) A product, other than a salt substitute, that is low, reduced or otherwise altered in sodium content cannot use the term "light" solely because of this alteration but rather shall use, as appropriate, the term "reduced sodium" or "low sodium."

(d) The term "light" or "lite" may be used to describe a salt substitute if the sodium content of the product has been reduced by at least 50 percent compared to ordinary table salt.

(e) The term "light" or "lite" may not be used to refer to a food that is not reduced in calories by ⅓ and, if applicable, in fat by 50 percent, unless:

(1) It describes some physical or organoleptic attribute of the food such as texture or color and the qualifying information (e.g., "light in color" or "light in texture") so stated clearly conveys the nature of the product; and

(2) The qualifying information is in the same type size, style, color, and prominence as the word "light" and in immediate proximity thereto.

(f) If a manufacturer can demonstrate that the word "light" has been associated, through common use, with a particular food (e.g., light brown sugar, light corn syrup, or light molasses) to the point where it has become part of the statement of identity, such use of the term "light" shall not be considered a nutrient content claim subject to the requirements in this part.

§ 101.60 Nutrient content claims for the calorie content of foods.

(a) *General requirements.* A claim about the calorie content of a food may only be made on the label and in the labeling of the food if:

(1) The claim uses one of the terms defined in this section in accordance with the definition for that term;

(2) The claim is made in accordance with the general requirements for nutrient content claims in § 101.13; and

(3) The food for which the claim is made is labeled in accordance with § 101.9 or, where applicable, § 101.36.

(b) *"Calorie content claims."* (1) The terms "calorie free," "free of calories," "no calories," "zero calories," "trivial source of calories," "negligible source of calories," or "dietarily insignificant source of calories" may be used on the label and in the labeling of a food provided that:

(i) The food contains less than 5 calories per reference amount customarily consumed and per labeled serving size; and

(ii) As required in § 101.13(e)(2), if the food meets this condition without the benefit of special processing, alteration, formulation, or reformulation to lower the caloric content, it is labeled to disclose that calories are not usually

present in the food (e.g., "soda water, a calorie free food").

(2) The terms "low calorie," "few calories," "contains a small amount of calories," or "low source of calories" "low in calories" may be used on the label and in labeling of foods except meal-type products as defined in § 101.13(1) provided that:

(i) The food does not provide more than 40 calories per reference amount customarily consumed, per labeled serving size, and, except for sugar substitute, per 100 grams (g); and

(ii) If a food meets these conditions without the benefit of special processing, alteration, formulation or reformulation to vary the caloric content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches (e.g., "celery, a low calorie food").

(3) The terms listed in paragraph (b)(2) of this section may be used on the label or in labeling of meal-type products as defined in § 101.13(1) provided that:

(i) The product contains 105 calories or less per 100 g; and

(ii) If the product meets this condition without the benefit of special processing, alteration, formulation, or reformulation to lower the calorie content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which it attaches.

(4) The terms "reduced calorie," "reduced in calories" or "calorie reduced" may be used to describe a food, except mealtype products as defined in § 101.13(1), provided that:

(i) The food has been specifically processed, altered, formulated, or reformulated, to reduce its calorie content by 33⅓ percent or more with a minimum reduction of more than 40 calories per reference amount customarily consumed and per labeled serving size from the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i) and (j)(1)(ii); and

(ii) As required in § 101.13(j)(2) for relative claims, the identity of the reference food, the percent (or fraction) that the calories have been reduced, and quantitative information comparing the level of the nutrient in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim (e.g., Reduced calorie cupcakes "33⅓% fewer calories than regular cupcakes. Calorie content has been reduced from 150 to 100 calories per serving").

(5) A comparative claim using the term "fewer" may be used on the label or in labeling of a food, including meal type products as defined in § 101.13(1), provided that:

(i) The food contains at least 25 percent fewer calories, with a minimum reduction of more than 40 calories per reference amount customarily consumed and per labeled serving size, than the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i), (j)(1)(ii), and (j)(1)(iii); and

(ii) As required in § 101.13(j)(2) for relative claims, the identity of the reference food, the percent (or fraction) that the calories have been reduced, and quantitative information comparing the level of the calories in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim (e.g., "This cheese cake contains 25 percent fewer calories than our regular cheese cake. Calorie content has been lowered from 200 to 150 calories per serving").

(c) *Sugars content claims*—(1) *Use of terms such as "sugars free," "no sugars," or "zero sugars."* Consumers may reasonably be expected to regard terms that represent that the food contains no sugars or sweeteners e.g., "sugar free," or "no sugars," as indicating that a product which is low in calories or significantly reduced in calories. Consequently, except as provided in paragraph (c)(2) of this section, a food may not be labeled with such terms unless:

(i) The food contains less than 0.5 g of sugars, as defined in § 101.9(c)(6)(ii)(A), per reference amount customarily consumed and per labeled serving size;

(ii) The food contains no added ingredients that are sugars; and

(iii)(A) it is labeled "low calorie" or "reduced calorie" or bears a comparative claim of special dietary usefulness labeled in compliance with paragraphs (b)(2), (b)(3), or (b)(4) of this section; or

(B) Such term is immediately accompanied, each time it is used, by either the statement "not a reduced calorie food," "not a low calorie food," or "not for weight control."

(2) The terms "no added sugars," "without added sugars," or "no sugars added" may be used only if:

(i) No amount of sugars as defined in § 101.9(c)(6)(ii)(A) is added during processing or packaging;

(ii) The product does not contain ingredients containing added sugars such as jam, jelly, and concentrated fruit juice;

(iii) The sugars content has not been increased above the amount naturally present in the ingredients by some means such as the use of enzymes;

(iv) The food that it resembles and for which it substitutes normally contains added sugars; and

(v) The product bears a statement indicating that the food is not low calorie or calorie reduced (unless the food meets the requirements for a low or reduced calorie food) and directing consumers' attention to the nutrition panel for further information on sugars and calorie content.

(3) Paragraph (c)(1) of this section shall not apply to a factual statement that a food is unsweetened or contains no added sweeteners in the case of a food that contains apparent substantial inherent sugar content, e.g., juices.

(4) A comparative claim using the term "less" may be used on the label or in labeling of a food, including meal type products as defined in § 101.13(l), provided that:

(i) The food contains at least 25 percent less sugars per reference amount customarily consumed and per labeled serving size than the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i), (j)(1)(ii), and (j)(1)(iii); and

(ii) As required in § 101.13(j)(2) for relative claims, the identity of the reference food, the percent (or fraction) that the sugars have been reduced, and quantitative information comparing the level of the sugars in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim (e.g., "These corn flakes contains 25 percent less sugars than our sugar coated corn flakes. Sugars content has been lowered from 8 g to 6 g per serving").

§ 101.61 Nutrient content claims for the sodium content of foods.

(a) *General requirements.* A claim about the level of sodium in a food may only be made on the label and in the labeling of the food if:

(1) The claim uses one of the terms defined in this section in accordance with the definition for that term;

(2) The claim is made in accordance with the general requirements for nutrient content claims in § 101.13; and

(3) The food for which the claim is made is labeled in accordance with § 101.9 or, where applicable, § 101.36.

(b) *"Sodium content claims."* (1) The terms "sodium free," "free of sodium," "no sodium," "zero sodium," "trivial source of sodium," "negligible source of sodium," or "dietary insignificant source of sodium" may be used on the label and in labeling of a food provided that:

(i) The food contains less than 5 milligrams (mg) of sodium per reference amount customarily consumed and per labeled serving size; and

(ii) The food does not contain any added sodium (sodium chloride) or other ingredient that contains sodium; and

(iii) As required in § 101.13(e)(2) if the food meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to lower the sodium content, it is labeled to disclose that sodium is not usually present in the food (e.g., "leaf lettuce, a sodium free food").

(2) The terms "very low sodium," or "very low in sodium," may be used on the label and in labeling of foods, except mealtype products as defined in § 101.13(l) provided that:

(i) The food contains 35 mg or less sodium per reference amount customarily consumed per labeled serving size, and per 100 grams (g) of food; and

(ii) If the food meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to vary the sodium content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches (e.g., "potatoes, a very low sodium food.").

(3) The term "very low sodium," or "very low in sodium," may be used on the label and in labeling of meal-type products as defined in § 101.13(l) provided that:

(i) The product contains 35 mg or less of sodium per 100 g of product; and

(ii) If the product meets this condition without the benefit of special processing, alteration, formulation, or reformulation to lower the sodium content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches.

(4) The terms "low sodium," or "low in sodium," "little sodium," "contains a small amount of sodium," or "low source of sodium" may be used on the label and in the labeling of foods, except meal-type products as defined in § 101.13(l), provided that:

(i) The food contains 140 mg or less sodium per reference amount customarily consumed, per labeled serving size, and per 100 g; and

(ii) If the food meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to vary the sodium content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches (e.g., "fresh spinach, a low sodium food").

(5) The terms listed in paragraph (b)(4) of this section may be used on the label and in labeling of meal-type products as defined in § 101.13(l) provided that:

(i) The product contains 140 mg or less sodium per 100 g of product; and

(ii) If the product meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to lower the sodium content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches.

(6) The term "reduced sodium," "reduced in sodium," or "sodium reduced" may be used on the label and in labeling, except meal-type products as defined in § 101.13(l) provided that:

(i) The food has been specifically processed, altered, formulated, or reformulated to reduce its sodium content by 50 percent or more with a minimum reduction of more than 140 mg per reference amount customarily consumed and per labeled serving size from the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i) and (j)(1)(ii); and

(ii) As required for § 101.13(j)(2) for relative claims, the identity of the reference food; the percent (or fraction) that the sodium has been reduced; and quantitative information comparing the level of the sodium in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim. (e.g., "reduced sodium—50 percent less sodium than regular peanuts. Sodium content has been reduced from 300 to 150 mg of sodium per serving").

(7) A comparative claim using the term "less" may be used on the label and in labeling of a food, including meal-type products as defined in § 101.13(l), provided that:

(i) The food contains at least 25 percent less sodium with a minimum reduction of more than 140 mg per reference amount customarily consumed and per labeled serving size than the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i), (j)(1)(ii), and (j)(1)(iii).

(ii) As required in § 101.13(j)(2) for relative claims, the identity of the reference food; the percent (or fraction) that the sodium has been decreased; and clear and concise quantitative information comparing the level of the sodium in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim. (e.g., "This tomato soup contains 25% less sodium than our regular tomato soup. Sodium content has been lowered from 500 to 375 mg per serving.")

(c) The term "salt" is not synonymous with "sodium." Salt refers to sodium chloride. However, references to salt content such as "unsalted," "no salt, "no salt added" are potentially misleading.

(1) The term "salt free" may be used on the label or in labeling of foods only if the food is "sodium free" as defined in paragraph (b)(1) of this section.

(2) The terms "unsalted," "without added salt," and "no salt added" may be used on the label or in labeling of foods only if:

(i) No salt is added during processing;

(ii) The food that it resembles and for which it substitutes is normally processed with salt; and

(iii) If the food is not sodium free, such claims are immediately accompanied each time they are used by the statement, "Not a sodium free food" or "Not for control of sodium in the diet."

§ 101.69 Petitions for nutrient content claims.

(a) This section pertains to petitions for claims, expressed or implied, that:

(1) Characterize the level of any nutrient which is of the type required to be in the label or labeling of food by section 403(q)(1) or (q)(2) of the Federal Food, Drug, and Cosmetic Act (the act); and

(2) That are not excepted under section 403(r)(5)(A) through (C) of the act from the requirements for such claims in section 403(r)(2).

(b) Petitions included in this section are:

(1) Petitions for a new (heretofore unauthorized) nutrient content claim;

(2) Petitions for a synonymous term (i.e., one that is consistent with a term defined by regulation) for characterizing the level of a nutrient; and

(3) Petitions for the use of an implied claim in a brand name.

(c) Petitions to be filed under the provisions of section 403(r)(4) of the act shall be submitted in quadruplicate. If any part of the material submitted is in a foreign language, it shall be accompanied by an accurate and complete English translation. The petition shall state the petitioner's post office address to which published notices as required by section 403 of the act may be sent.

(d) Pertinent information may be incorporated in, and will be considered as part of, a petition on the basis of specific reference to such information submitted to and retained in the files of the Food and Drug Administration. However, any reference to unpublished information furnished by a person other

than the applicant will not be considered unless use of such information is authorized (with the understanding that such information may in whole or part be subject to release to the public) in a written statement signed by the person who submitted it. Any reference to published information should be accompanied by reprints or photostatic copies of such references.

(e) If nonclinical laboratory studies are included in a petition submitted under section 403(r)(4) of the act, the petition shall include, with respect to each nonclinical study contained in the petition, either a statement that the study has been, or will be, conducted in compliance with the good laboratory practice regulations as set forth in Part 58 of this chapter or, if any such study was not conducted in compliance with such regulations, a brief statement of the reason for the noncompliance.

(f) If clinical investigations are included in a petition submitted under section 403(r)(4) of the act, the petition shall include a statement regarding each such clinical investigation relied upon in the petition that the study either was conducted in compliance with the requirements for institutional review set forth in part 56 of this chapter or was not subject to such requirements in accordance with § 56.104 or § 56.105, and that it was conducted in compliance with the requirements for informed consent set forth in part 50 of this chapter.

(g) The availability for public disclosure of petitions submitted to the agency under this section will be governed by the rules specified in § 10.20(j) of this chapter.

(h) All petitions submitted under this section shall include either a claim for a categorical exclusion under § 25.24 of this chapter or an environmental assessment under § 25.31.

(i) The data specified under the several lettered headings should be submitted on separate sheets or sets of sheets, suitably identified. If such data have already been submitted with an earlier application from the petitioner, the present petition may incorporate it by specific reference to the earlier petition.

(j) The petition must be signed by the petitioner or by his attorney or agent, or (if a corporation) by an authorized official.

(k) The petition shall include a statement signed by the person responsible for the petition, that to the best of his knowledge, it is a representative and balanced submission that includes unfavorable information, as well as favorable information, known to him pertinent to the evaluation of the petition.

(l) All applicable provisions of Part 10—Administrative Practices and Procedures, may be used by the Commissioner of Food and Drugs, the petitioner or any outside party with respect to any agency action on the petition.

(m)(1) Petitions for a new nutrient content claim shall include the following data and be submitted in the following form.

(Date)
Name of petitioner _____
Post office address _____
Subject of the petition _____
Regulations and Industry Activities Branch (HFF–312),
Food and Drug Administration,
Department of Health and Human Services,
Washington, DC 20204.
Dear Sirs:

The undersigned, _____ submits this petition under section 403(r)(4) of the Federal Food, Drug, and Cosmetic Act (the act) with respect to (statement of the claim and its proposed use).

Attached hereto, in quadruplicate, and constituting a part of this petition, are the following:

A. A statement identifying the descriptive term and the nutrient that the term is intended to characterize with respect to the level of such nutrient. The statement should address why the use of the term as proposed will not be misleading. The statement should provide examples of the nutrient content claim as it will be used on labels or labeling, as well as the types of foods on which the claim will be used. The statement shall specify the level at which the nutrient must be present or what other conditions concerning the food must be met for the use of the term in labels or labeling to be appropriate, as well as any factors that would make the use of the term inappropriate.

B. A detailed explanation, supported by any necessary data, of why use of the food component characterized by the claim is of importance in human nutrition by virtue of its presence or absence at the levels that such claim would describe. This explanation shall also state what nutritional benefit to the public will derive from use of the claim as proposed, and why such benefit is not available through the use of existing terms defined by regulation under section 403(r)(2)(A)(i) of the act. If the claim is intended for a specific group within the population, the analysis should specifically address nutritional needs of such group, and should include scientific data sufficient for such purpose. The petition shall include data and information, e.g., surveys to the extent necessary, to demonstrate that consumers can be expected to understand the meaning of the term under the proposed conditions of use.

C. Analytical data that shows the amount of the nutrient that is the subject of the claim and that is present in the types of foods for which the claim is intended. The assays should be performed on representative samples using the Association of Official Analytical Chemists (AOAC) methods where available. If no AOAC method is available, the petitioner shall submit the assay method used, and data establishing the validity of the method for assaying the nutrient in the particular food. The validation data should include a statistical analysis of the analytical and product variability.

D. A detailed analysis of the potential effect of the use of the proposed claim on food consumption and of any corresponding changes in nutrient intake. The latter item shall specifically address the intake of nutrients that have beneficial and negative consequences in the total diet. If the claim is intended for a specific group within the population, the above analysis shall specifically address the dietary practices of such group and shall include data sufficient to demonstrate that the dietary analysis is representative of such group.

Yours very truly,
Petitioner _____
By _____
(Indicate authority)

(2) Within 15 days of receipt of the petition, the petitioner will be notified by letter of the date on which the petition was received by the agency. Such notice will inform the petitioner:

(i) That the petition is undergoing agency review (in which case a docket number will be assigned to the petition), and the petitioner will subsequently be notified of the agency's decision to file or deny the petition; or

(ii) That the petition is incomplete, e.g., it lacks any of the data required by this part, it presents such data in a manner that is not readily understood, or it has not been submitted in quadruplicate, in which case the petition will be denied, and the petitioner will be notified as to what respect the petition is incomplete.

(3) Within 100 days of the date of receipt of the petition, the Commissioner of Food and Drugs will notify the petitioner by letter that the petition has either been filed or denied. If denied, the notification shall state the reasons therefor. If filed, the date of the notification letter becomes the date of filing for the purposes of section 403(r)(4)(A)(i) of the act. A petition that has been denied shall not be made available to the public. A filed petition shall be available to the public as provided under paragraph (e) of this section.

(4) Within 90 days of the date of filing the Commissioner of Food and Drugs will by letter of notification to the petitioner:

(i) Deny the petition; or

(ii) Inform the petitioner that a proposed regulation to provide for the requested use of the new term will be

published in the **Federal Register**. The Commissioner of Food and Drugs will publish the proposal to amend the regulations to provide for the requested use of the nutrient content claim in the **Federal Register** within 90 days of the date of filing. The proposal will also announce the availability of the petition for public disclosure.

(n)(1) Petitions for a synonymous term shall include the following data and be submitted in the following form.

(Date)
Name of petitioner ———
Post office address ———
Subject of the petition ———
Regulations and Industry Activities Branch (HFF–312),
Food and Drug Administration,
Department of Health and Human Services,
Washington, DC 20204.
Dear Sirs:

The undersigned, _____ submits this petition under section 403(r)(4) of the Federal Food, Drug, and Cosmetic Act (the act) with respect to (statement of the synonymous term and its proposed use in a nutrient content claim that is consistent with an existing term that has been defined under section 403(r)(2) of the act).

Attached hereto, in quadruplicate, and constituting a part of this petition, are the following:

A. A statement identifying the synonymous descriptive term, the existing term defined by a regulation under section 403(r)(2)(A)(i) of the act with which the synonymous term is claimed to be consistent. The statement should address why the use of the synonymous term as proposed will not be misleading. The statement should provide examples of the nutrient content claim as it will be used on labels or labeling, as well as the types of foods on which the claim will be used. The statement shall specify whether any limitations not applicable to the use of the defined term are intended to apply to the use of the synonymous term.

B. A detailed explanation, supported by any necessary data, of why use of the proposed term is requested, including an explanation of whether the existing defined term is indequate for the purpose of effectively characterizing the level of a nutrient. This item shall also state what nutritional benefit to the public will derive from use of the claim as proposed, and why such benefit is not available through the use of existing term defined by regulation. If the claim is intended for a specific group within the population, the analysis should specifically address nutritional needs of such group, and should include scientific data sufficient for such purpose. This item shall include data and information, e.g., surveys, to the extent necessary to demonstrate that consumers can be expected to understand the meaning of the term under the proposed conditions of use.

C. A detailed analysis of the potential effect of the use of the proposed claim on food consumption and of any corresponding changes in nutrient intake. The latter item shall specifically address the intake of nutrients that have beneficial and negative consequences in the total diet. If the claim is intended for a specific group within the population, the above analysis shall specifically address the dietary practices of such group and shall include data sufficient to demonstrate that the dietary analysis is representative of such group.

Yours very truly,
Petitioner ———
By ———
(Indicate authority)

(2) Within 15 days of receipt of the petition the petitioner will be notified by letter of the date on which the petition was received. Such notice will inform the petitioner:

(i) that the petition is undergoing agency review (in which case a docket number will be assigned to the petition) and the petitioner will subsequently be notified of the agency's decision to grant the petitioner permission to use the proposed term or to deny the petition; or

(ii) that the petition is incomplete, e.g., it lacks any of the data required by this part, it presents such data in a manner that is not readily understood, or it has not been submitted in quadruplicate, in which case the petition will be denied, and the petitioner will be notified as to what respect the petition is incomplete.

(3) Within 90 days of the date of receipt of the petition that is accepted for review (i.e., that has not been found to be incomplete and consequently denied, the Commissioner of Food and Drugs will notify the petitioner by letter of the agency's decision to grant the petitioner permission to use the proposed term, with any conditions or limitations on such use specified, or to deny the petition, in which case the letter shall state the reasons therefor. Failure of the petition to fully address the requirements of this section shall be grounds for denial of the petition.

(4) As soon as practicable following the granting of a petition, the Commissioner of Food and Drugs will publish a notice in the **Federal Register** informing the public of his decision. If the petition is granted the Food and Drug Administration will list, the approved synonymous term in the regulations listing terms permitted for use in nutrient content claims.

(o)(1) Petitions for the use of an implied nutrient content claim in a brand name shall include the following data and be submitted in the following form:

(Date)
Name of petitioner ———
Post office address ———
Subject of the petition ———
Regulations and Industry Activities Branch (HFF–312),
Food and Drug Administration,
Department of Health and Human Services,
Washington, DC 20204.
Dear Sirs:

The undersigned, _____ submits this petition under section 403(r)(4) of the Federal Food, Drug, and Cosmetic Act (the act) with respect to (statement of the implied nutrient content claim and its proposed use in a brand name).

Attached hereto, in quadruplicate, and constituting a part of this petition, are the following:

A. A statement identifying the implied nutrient content claim, the nutrient the claim is intended to characterize, the corresponding term for characterizing the level of such nutrient as defined by a regulation under section 403(r)(2)(A)(i) of the act, and the brand name of which the implied claim is intended to be a part. The statement should address why the use of the brand-name as proposed will not be misleading. It should address in particular what information is required to accompany the claim or other ways in which the claim meets the requirements of sections 403(a) and 201(n) of the act. The statement should provide examples of the types of foods on which the brand name will appear. It shall also include data showing that the actual level of the nutrient in the food qualifies the food to bear the corresponding term defined by regulation. Assay methods used to determine the level of a nutrient should meet the requirements stated under petition format item C in paragraph (k)(1) of this section.

B. A detailed explanation, supported by any necessary data, of why use of the proposed brand name is requested. This item shall also state what nutritional benefit to the public will derive from use of the brand name as proposed. If the branded product is intended for a specific group within the population, the analysis should specifically address nutritional needs of such group and should include scientific data sufficient for such purpose.

C. A detailed analysis of the potential effect of the use of the proposed brand name on food consumption and of any corresponding changes in nutrient intake. The latter item shall specifically address the effect on the intake of nutrients that have beneficial and negative consequences in the total diet. If the branded product is intended for a specific group within the population, the analysis should specifically address the dietary practices of such group, and should include data sufficient to demonstrate that the dietary analysis is representative of such group.

Yours very truly,
Petitioner ———
By ———

(2) Within 15 days of receipt of the petition the petitioner will be notified by letter of the date on which the petition was received. Such notice will inform the petitioner:

(i) That the petition is undergoing agency review (in which case a docket number will be assigned to the petition); or

(ii) That the petition is incomplete, e.g., one that lacks any of the data required by this part, one that states such data in a manner that is not readily understood, or it has not been submitted in quadruplicate, in which case the petition will be denied, and the petitioner will be notified as to what respect the petition is incomplete.

(3) The Commissioner of Food and Drugs will publish a notice of the petition in the Federal Register announcing its availability to the public and seeking comment on the petition. The petition shall be available to the public to the extent provided under paragraph (e) of this section. The notice shall allow 30 days for comments.

(4) Within 100 days of the date of receipt of the petition that is accepted for review (i.e., that has not been found to be incomplete and subsequently returned to the petitioner), the Commissioner of Food and Drugs will:

(i) Notify the petitioner by letter of the agency's decision to grant the petitioner permission to use the proposed brand name if such use is not misleading, with any conditions or limitations on such use specified; or

(ii) Deny the petition, in which case the letter shall state the reasons therefor. Failure of the petition to fully address the requirements of this section shall be grounds for denial of the petition. Should the Commissioner of Food and Drugs not notify the petitioner of his decision on the petition within 100 days, the petition shall be considered to be granted.

(5) As soon as practicable following the granting of a petition, the Commissioner of Food and Drugs will publish a notice in the Federal Register informing the public of such fact.

6. Subpart F is redesignated as Subpart G and new Subpart F is added to read as follows:

SUBPART F—SPECIFIC REQUIREMENTS FOR CLAIMS THAT ARE NEITHER NUTRIENT CONTENT CLAIMS OR HEALTH CLAIMS

§ 101.95 "Fresh", "freshly," "fresh frozen", "frozen fresh."

The terms defined in this section may be used on the label or in labeling of a food only in conformity with the provisions of this section. The requirements of the section pertain to any use of the subject terms that expressly or implicitly refers to the food on labels or labeling, including use in a brand name and use as a sensory modifier.

(a) The term "fresh," which may be used only on the label of a raw food, means that the food has not been frozen or subjected to any form of thermal processing or any other form of preservation, except as provided in paragraph (d) of this section.

(b) The term "freshly_____" (the blank being filled with an appropriate verb, e.g., "prepared," "baked," "roasted"), which may be used on the label of a prepared or produced food, means that the food is recently made or prepared and has not been frozen, or subjected to any form of thermal processing, or any other form of preservation (except as provided in paragraph (d) of this section) during or subsequent to its manufacture or preparation, except a process inherent to the production of the basic food.

(c) The terms "fresh frozen" and "frozen fresh," when used on the label or in labeling of a food, mean that the food was quickly frozen while still fresh (i.e., the food had been recently harvested when frozen). "Quickly frozen" means frozen by a freezing system such as blast-freezing (sub-zero Fahrenheit temperature with fast moving air directed at the food) that ensures the food is frozen, even to the center of the food, quickly and that virtually no deterioration has taken place.

(b) Provisions and restrictions. (1) The addition of approved waxes or coatings, the post-harvest use of approved pesticides, or the application of a mild chlorine wash or mild acid wash on raw produce, does not preclude the food from use of the term "fresh."

(2) A food meeting the definition in paragraph (a) or (b) of this section that is refrigerated, is not precluded from use of "fresh" and "freshly prepared," as provided by this section.

(3) A food shall not be considered to be recently prepared or made if it is available for sale more than 24 hours after its preparation or production.

PART 105—FOODS FOR SPECIAL DIETARY USE

7. The authority citation for 21 CFR part 105 continues to read as follows:

Authority: Secs. 201, 401, 403, 409, 411, 701, 706 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 341, 343, 348, 350, 371, 376).

8. Section 105.66 is revised to read as follows:

§ 105.66 Label statements relating to usefulness in reducing or maintaining body weight.

(a) *General requirements.* Any food that purports to be or is represented for special dietary use because of usefulness in reducing or maintaining body weight shall bear:

(1) Nutrition labeling in conformity with § 101.9, or, where applicable, § 101.36 of this chapter, unless exempt under that section; and

(2) A conspicuous statement of the basis upon which the food claims to be of special dietary usefulness.

(b) *Nonnutritive ingredients.* (1) Any food subject to paragraph (a) of this section that achieves its special dietary usefulness by use of a nonnutritive ingredient (i.e., one not utilized in normal metabolism) shall bear on its label a statement that it contains a nonnutritive ingredient and the percentage by weight of the nonnutritive ingredient.

(2) A special dietary food may contain a nonnutritive sweetener or other ingredient only if the ingredient is safe for use in the food under the applicable law and regulations of this chapter. Any food that achieves its special dietary usefulness in reducing or maintaining body weight through the use of a nonnutritive sweetener shall bear on its label the statement required by paragraph (b)(1) of this section, but need not state the percentage by weight of the nonnutritive sweetener. If a nutritive sweetener(s) as well as nonnutritive sweetener(s) is added, the statement shall indicate the presence of both types of sweetener, e.g., "Sweetened with nutritive sweetener(s) and nonnutritive sweetener(s)."

(c) *"Low calorie" foods.* A food purporting to be "low calorie" must comply with the criteria set forth for such foods in § 101.60(b)(2) and (b)(3) of this chapter.

(d) *"Reduced calorie" foods and other comparative claims.* A food purporting to be "reduced calorie" or otherwise containing fewer calories than a reference food must comply with the criteria set forth for such foods in § 101.60(b)(4) and (b)(5) of this chapter.

(e) *Label terms suggesting usefulness as low calorie or reduced calorie foods.* (1) Except as provided in paragraph (e)(2) of this section, and in § 101.13(o)(2) of this chapter for soft drinks, a food, including a formulated meal replacement, or other food that is represented to be of special dietary use as a whole meal, may be labeled with the terms "diet," "dietetic," "artificially sweetened," or "sweetened with nonnutritive sweetener" only if the claim is not false or misleading, and the food is labeled "low calorie" or "reduced calorie" or bears a comparative claim of special dietary usefulness in compliance with part 101 of this chapter and this section.

(2) Paragraph (e)(1) of this section shall not apply to any use of such terms

that is specifically authorized by regulation governing a particular food, or unless otherwise restricted by regulation, to any use of the term "diet" that clearly shows that the food is offered solely for dietary use other than regulating body weight, e.g., "for low-sodium diets."

(f) *"Sugars free", and "no added sugars"*. Criteria for the use of the terms "sugars free" and "no added sugars" are provided for in § 101.60(c) of this chapter.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

21 CFR Part 101

[Docket No. 84N-0153]

RIN 0905-AB68

Food Labeling: Definitions of Nutrient Content Claims for the Fat, Fatty Acid, and Cholesterol Content of Food

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to amend the food labeling regulations to define, and to provide for the proper use of, the terms "fat free," "low fat," "reduced fat," "low in saturated fat," "reduced saturated fat," "cholesterol free," "low cholesterol," and "reduced cholesterol" in the labeling of foods and to provide for the use of other truthful and nonmisleading statements about a food's fat, fatty acid, and cholesterol content in food labeling. This proposed rule is intended to permit meaningful declarations about fat, fatty acid, and cholesterol content, while preventing misleading claims about these food components. In this document, FDA is responding to comments received in response to the tentative final rule on cholesterol claims (55 FR 29456, July 19, 1990) and to the provisions of the Nutrition Labeling and Education Act of 1990 regarding fat, fatty acid, and cholesterol content claims. In addition, this document sets forth related agency policies.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may be issued based upon this proposal become effective 6 months following its publication in accordance with the provisions of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, Rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Virginia L. Wilkening, Center for Food Safety and Applied Nutrition (HFF-204), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-245-1561.

SUPPLEMENTARY INFORMATION:

I. Introduction

A. Regulatory History of Fat, Fatty Acid, and Cholesterol Labeling

The agency has had a long interest in the proper labeling of foods with information on fat, fatty acid, and cholesterol content. FDA's policies have reflected contemporary knowledge on the relationship between these dietary components and chronic disease conditions.

1. The 1959 Policy Statement

In the **Federal Register** of December 10, 1959 (24 FR 9990), the agency published a statement of policy concerning the status of food offered to the general public for the control or reduction of blood cholesterol levels and for the prevention and treatment of heart and artery disease. The policy statement acknowledged the public interest in the effect of various fatty foods on blood cholesterol and the relationship between blood cholesterol levels and diseases of the heart and arteries. However, the statement noted that the role of dietary cholesterol in heart and artery diseases had not been established. Therefore, FDA took the position that any labeling claim for fats and oils that indicated or implied that a food would prevent, mitigate, or cure diseases of the heart or arteries would be considered false or misleading and would misbrand the food under the Federal Food, Drug, and Cosmetic Act of 1938 (the act). FDA pointed out that the policy statement was not intended to interfere with clinical research on the possible role of dietary unsaturated fats in lowering blood cholesterol. The policy statement was, the agency stated, intended to prevent the promotion of foods for use by the public without medical supervision.

2. Quantitative Labeling of Fatty Acid and Cholesterol Content

In the **Federal Register** of May 25, 1965 (30 FR 6984), the agency proposed to establish requirements for label statements relating to oils, fats, and fatty foods used as a means of reducing the dietary intake of fatty acids. FDA received a number of comments on this proposal. After considering the comments and other available information, FDA terminated the rulemaking (31 FR 3301, March 2, 1966) because comments convinced the agency that the role of fats in the diet had not been sufficiently studied to make a definitive decision.

In the 5 years that followed, the terms "saturated," "monounsaturated," and "polyunsaturated," as applied to food fats or fatty acids, received considerable publicity, which led to consumer demand for more information about fat-containing foods. In 1970, the White House Conference on Food, Nutrition, and Health recommended that regulatory agencies permit and encourage the food industry, on a voluntary basis, to label the fat and fatty acid content of foods that constitute the major sources of fats in typical diets (Ref. 1).

Accordingly, in response to the consumer requests and to a report of the American Medical Association's Council on Foods and Nutrition, which contained a number of recommendations regarding the labeling of fat and fatty acids, FDA proposed in the **Federal Register** of June 15, 1971 (36 FR 11521) to adopt a regulation (21 CFR 125.12) on the requirements for label statements intended to provide guidance for regulating intake of fatty acids. This proposal would have established labeling requirements for foods represented for special dietary use containing 10 percent or more fat on a dry weight basis and no less than 3 grams (g) of fat in an average serving.

In the same issue of the **Federal Register** (36 FR 11521), FDA also proposed to amend the agency's policy statement on labeling foods for the prevention and treatment of heart and artery disease to make it clear that claims such as "lower cholesterol" were deemed to be false or misleading. However, the agency also proposed to provide that labeling statements would be acceptable if they set out only the fat content of the food, the source of the fat, and the content of saturated, monounsaturated, and polyunsaturated fatty acids in accordance with proposed § 125.12.

After considering the comments on these proposals and other available information, FDA concluded that information associated with the cholesterol and fatty acid content of foods should be combined into a single regulation. Accordingly, in the **Federal Register** of January 19, 1973 (38 FR 2132)

(amended March 14, 1973, 38 FR 6961) FDA removed the 1959 policy statement and established a new § 1.18 *Labeling of foods in relation to the fat and fatty acid and cholesterol content* (21 CFR 1.18; recodified as 21 CFR 101.25 in the **Federal Register** of March 15, 1977 (42 FR 14302)), which established requirements for labeling the cholesterol and fatty acid composition of food products. (Requirements for labeling the fat content of food were included in the rulemaking for general nutrition labeling (38 FR 2132) (amended March 14, 1973, 38 FR 6951).)

Section 101.25 provides for the voluntary listing of the cholesterol and fatty acid content of the food as part of the food's nutrition labeling (21 CFR 101.9). This regulation provides that cholesterol be declared (to the nearest 5-milligram (mg) increment) in mg per serving and in mg per 100 g of food, and that fatty acid content be declared (to the nearest g) in g per serving in two categories: "Polyunsaturated fatty acids" and "saturated fatty acids." It limits fatty acid declarations to foods containing not less than 2 g of fat per serving and 10 percent or more fat on a dry weight basis. FDA said that any food that contains less than these levels was deemed "not suitable for use by man as a means of regulating the intake of fatty acids" (§ 101.25(c)(1)). In other words, FDA believed that foods that contained less than these levels were so low in fat as to not be a significant source of fatty acids, and, thus, that lowering the levels at which these foods were eaten would not affect blood cholesterol levels. Therefore, FDA decided that such foods should not be permitted to bear claims about the relative amounts of polyunsaturated fatty acids in such small amounts of fat. Since FDA promulgated this provision (currently codified as § 101.25(c)(1)), the agency has advised those who have requested guidance on the use of the term "low fat" that "a definition for the term 'low fat' can be inferred from § 101.25(c)(1)" (Ref. 2). The definition that FDA is proposing in this document for "low fat" differs from these criteria.

3. Food Standards

In addition to issuing 21 CFR 101.25, the agency, in response to recommendations in the 1970 report of the White House Conference on Food, Nutrition, and Health (Ref. 1), issued a limited number of food standard regulations that describe nonfat and lowfat food products. Food standards specifically prescribe the composition and name of particular products to protect the public from economic fraud. Presently, the agency has food standards of identity for various types of nonfat and lowfat milk products (21 CFR part 131), lowfat cottage cheese (21 CFR part 133), nonfat and lowfat yogurt (21 CFR part 131), macaroni products containing nonfat milk (21 CFR part 139), and low-fat cocoa (21 CFR 163.114).

4. The 1978 Food Labeling Initiative

In the **Federal Register** of June 9, 1978 (43 FR 25296), FDA, the U.S. Department of Agriculture (USDA), and the staff of the Federal Trade Commission's Bureau of Consumer Protection published a notice requesting the public's views on numerous food labeling issues and announcing public hearings across the nation to elicit comments on improving food labeling.

The results of the joint hearings were published in a notice in the **Federal Register** of December 21, 1979 (44 FR 75990). In that notice, FDA announced its plans to undertake a major food labeling initiative, including its plans to propose regulations to define cholesterol claims in food labeling and to consider proposing regulations to define fatty acid claims in food labeling.

5. The 1986 Proposed Cholesterol Nutrient Content Claims

In the **Federal Register** of November 25 1986 (51 FR 42584), FDA published a proposal to define terms that describe the cholesterol content of foods and to provide for their proper use in food labeling. FDA proposed to amend § 101.25 to define the terms "cholesterol free," "low cholesterol," and "reduced cholesterol" and to provide for truthful comparative statements that describe significant reductions in cholesterol content. Specifically, FDA proposed that "cholesterol free" be defined as less than 2 mg of cholesterol per serving, "low cholesterol" as less than 20 mg of cholesterol per serving, and "reduced cholesterol" as a 75 percent reduction. FDA proposed to require that whenever these terms or statements about cholesterol content appear on labels, the amount of cholesterol be declared in the nutrition label. FDA also proposed to amend § 101.9, the nutrition labeling regulation, to require that when cholesterol content is declared on the nutrition label, fatty acid content also be declared, and that when fatty acid content is declared, cholesterol content also be declared. FDA received over 1,000 comments in response to this proposal.

B. Current Food Labeling Initiative

1. The 1989 ANPRM

In the **Federal Register** of August 8, 1989 (54 FR 32610), FDA published an advance notice of proposed rulemaking (ANPRM) that announced a major initiative of the Department of Health and Human Services (DHHS) to take a new look at food labeling as a tool for promoting sound nutrition for the nation's consumers. FDA asked for public comment on five areas of food labeling, including the use of nutrient content claims such as "cholesterol free" to characterize foods.

In response to the ANPRM, FDA received over 2,000 written comments, plus over 5,000 copies of a questionnaire that had been distributed by a consumer organization. Over 500 of the written comments addressed issues related to specific nutrient content claims. These comments made clear that both consumers and food manufacturers are strongly in favor of improving food labels and, in particular, that FDA should define additional food nutrient content claims. In addition, approximately 3,500 of the over 5,000 questionnaires supported the need for additional descriptor definitions. Many comments stated that the proliferation of undefined terms has resulted in confusion for consumers and unfair competition for manufacturers. One comment stated that terms are "meaningless the way they are used now and are primarily used as marketing tools rather than guides for the health conscious consumer." Many comments suggested that commonly used nutrient content claims should either be defined by FDA or not permitted.

As part of this DHHS initiative, FDA announced in the **Federal Register** of September 20, 1989 (54 FR 38806) a series of four public hearings to discuss nutrition labeling and other issues related to food labeling, including the use of nutrient content claims. Representing a cross-section of interested parties, some 200 people including consumers, health professionals, trade associations, other industry representatives, and State and local health officials, testified at these hearings. In addition, 1,500 more persons participated in 50 local "consumer exchange" meetings conducted by FDA. Comments received as a result of the ANPRM and testimony from people at the hearings approved of FDA's past efforts to define terms relating to the content of calories, sodium, and cholesterol. The comments supported FDA's basic approach of defining terms such as "no ____," "low ____," and "reduced ____." They urged FDA to proceed immediately to define the other terms that are commonly used, giving priority to terms with the greatest

impact on public health. There was general agreement that top priority should be given to the terms that describe the fat content of foods.

On March 7, 1990, Secretary of Health and Human Services, Louis W. Sullivan, announced that FDA would undertake a comprehensive, phased response to the comments on the ANPRM. Subsequently, FDA prepared and published, in the **Federal Register** of July 19, 1990, three proposed rules that would: (1) Make nutrition labeling mandatory on foods that are a meaningful source of nutrients and revise the content of the nutrition label (55 FR 29487); (2) establish standard serving sizes (55 FR 29517); and (3) establish reference values for declaring nutrient and other food component content in nutrition labeling (55 FR 29476). In the same issue of the **Federal Register**, FDA published a tentative final rule defining terms that may be used in food labeling to describe the cholesterol content of foods.

2. Tentative Final Rule on Cholesterol Nutrient Content Claims

In the tentative final rule that published in the **Federal Register** on July 19, 1990 (55 FR 29456), FDA addressed the comments received in response to the proposed rule on cholesterol nutrient content claims (51 FR 42584, November 25, 1986) as well as the comments received in response to the 1989 ANPRM and the public hearings. Many of the comments requested that FDA limit the amount of fat and of saturated fatty acids in foods claiming to be "cholesterol free" or "low in cholesterol." FDA agreed with these comments and in the tentative final rule (55 FR 29456) proposed to limit the content of fat and saturated fatty acids in foods bearing these claims. FDA proposed to limit the use of the terms "cholesterol free" and "low cholesterol" to foods that contain not more than 5 g of fat and not more than 2 g of saturated fatty acids per serving, as well as the requisite cholesterol levels. On a dry weight basis, these foods could contain not more than 20 percent fat and not more than 6 percent saturated fatty acids.

The requisite cholesterol levels remained the same as proposed in the 1986 proposal, except that FDA proposed: (1) To define "low cholesterol" as "20 mg or less of cholesterol per serving" rather than as "less than 20 mg per serving," and (2) to add a second criterion based on density to the definition of "low cholesterol," namely that the food contain 0.2 mg or less cholesterol per g of food. The first change was made to be consistent with FDA's other definitions for "low," for calories (§ 105.66(c)(1)(i)) and for sodium (§ 101.13(a)(3)), that include the integer in the definition.

FDA made the second change to prevent "low cholesterol" label claims from conveying a misleading impression about the cholesterol content of certain foods. Comments pointed out that a single criterion based on serving size could result in widely recognized "high cholesterol" foods with small serving sizes (e.g., butter, lard, and some processed cheese foods) being labeled as "low cholesterol". These comments stressed that despite their small serving sizes, such foods actually may be consumed frequently and in large amounts, resulting in a substantial total daily intake of cholesterol. In addition, the comments were concerned that a "low cholesterol" claim on such foods could encourage increased consumption of the food, significantly adding to an individual's total cholesterol intake.

Additionally, in the tentative final rule FDA proposed to limit comparative statements about cholesterol content to products with at least a 25 percent reduction in cholesterol content. This requirement was added to prevent deceptive comparative claims and to help ensure that consumers are not misled into believing that an inconsequential reduction in cholesterol content will provide significant health benefits.

FDA advised that it considered the tentative final rule to contain the agency's final determination on all substantive issues other than on the threshold levels of fat and saturated fatty acids, and that a comment would have to be very significant to make any changes in the rule other than to the threshold levels.

3. Nutrition Labeling

On July 19, 1990, FDA also published a proposed rule (55 FR 29487) (the mandatory nutrition labeling proposal) to require nutrition labeling on most foods that are meaningful sources of nutrients and to revise the list of nutrients required to be declared. The agency proposed to require that nutrition labeling include fat, saturated fat (which could also be declared as "saturated"), and cholesterol content of the food, as well as the amount of calories from fat. In addition, the following items could be included voluntarily: unsaturated fat (which the proposal said could also be stated as "unsaturated" or, alternatively, as "monounsaturated" and "polyunsaturated"), calories from unsaturated fat, and calories from saturated fat.

The agency proposed that the listing of unsaturated fatty acid content would be mandatory when a claim is made about fatty acids or cholesterol, or when calories from unsaturated fatty acids are voluntarily declared. Moreover, under the proposal, the specific listing of the monounsaturated and polyunsaturated fatty acid content would become mandatory when a claim is made about a particular type of unsaturated fatty acid. Finally, the agency proposed to prohibit any claim that a food is nutritionally superior to another food in fat or saturated fatty acid content unless the level of these substances is at least 25 percent less than in the food to which the comparison is being made.

4. Reference Daily Intake (RDI) and Daily Reference Values (DRV)

In a proposed rule related to nutrition labeling (55 FR 29476, July 19, 1990) (the RDI/DRV proposal), FDA updated the U.S. Recommended Daily Allowances (U.S. RDA's) used in food labeling and proposed to replace the term "U.S. RDA" with "Reference Daily Intake". In the same proposal, the agency also introduced the term "Daily Reference Value" and proposed DRV's for seven food components, including total fat (75 g), saturated fatty acids (25 g), unsaturated fatty acids (50 g), and cholesterol (300 mg). These DRV's are based upon a diet of 2,350 calories, which is the population-adjusted mean of the recommended energy allowances for persons 4 or more years of age, as indicated in the 10th edition of the "Recommended Dietary Allowances" (Ref. 3). The DRV for cholesterol is, however, independent of calories.

5. Serving Size

FDA proposed standardized serving sizes for the major categories of foods in a third proposed rule (55 FR 29517, July 19, 1990) to assure reasonable serving sizes and to provide for comparison among similar products. FDA said that these serving sizes, if adopted, would ensure that claims, such as "low cholesterol," were the result of the characteristics of the food and not manipulation of the serving size. The agency stated that these standardized serving sizes would help to ensure that food label claims are not misleading to consumers.

6. Institute of Medicine Report

On September 26, 1990, the National Academy of Sciences (NAS's) Institute of Medicine (IOM) issued a report entitled "Nutrition Labeling: Issues and Directions for the 1990's" (the IOM report) (Ref. 4). The IOM report was

written under contract to the Public Health Service, DHHS, and the Food Safety and Inspection Service, USDA. This report makes recommendations for changes in food labeling that will assist consumers in implementing the recommendations of "The Surgeon General's Report on Nutrition and Health" (Ref. 5) (the Surgeon General's Report) and NAS's recent report, "Diet and Health, Implications for Reducing Chronic Disease Risk" (Ref. 6) (the NAS report). The IOM report recommends, among other things, that FDA define nutrient content claims for fat, fatty acid, and cholesterol content.

7. Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) (Pub. L. 101–535). The 1990 amendments make the most significant changes in food labeling law since passage of the act. They strengthen DHHS's food labeling initiative by clarifying FDA's legal authority to require nutrition labeling on foods and by defining the circumstances under which claims may be made about the nutrients in foods. Section 403(r)(1)(A) of the act (21 U.S.C. 343(r)(1)(A)), which was added by the 1990 amendments, states that a food is misbranded if a claim is made in its label or labeling that characterizes the levels of any nutrient of the type required in nutrition labeling under section 403(q) of the act, including fat, fatty acids, and cholesterol, unless the claim is made in a manner that conforms to the requirements of the act. These requirements, and the agency's proposed regulations implementing these requirements, are generally discussed in a companion proposed rule entitled "Food Labeling; Nutrient Content Claims, General Principles, Petitions, Definition of Terms" published elsewhere in this issue of the **Federal Register** (hereinafter referred to as the "companion document on nutrient content claims"). However, the requirements that specifically apply to nutrient content claims (synonymously referred to as "nutrient content claims") with respect to fat, fatty acids, and cholesterol are the subject of this document.

The 1990 amendments directly affect FDA's tentative final rule on cholesterol claims of July 19, 1990. Because a number of changes in the tentative final rule are necessary to bring it into conformity with the requirements of the 1990 amendments, the agency is issuing this new proposed rule on cholesterol nutrient content claims. In doing so, the agency is including proposed definitions for fat and fatty acid nutrient content claims in this document because of the interrelationship among these components and cholesterol in the etiology of cardiovascular disease. The agency is also providing for the use of other truthful and nonmisleading comparative statements about the levels of fat, fatty acids, and cholesterol in foods.

8. Supplementary Nutrition Labeling Proposal

Elsewhere in this issue of the **Federal Register**, FDA is publishing a reproposal entitled "Food Labeling: Reference Daily Intakes and Daily Reference Values; Mandatory Status of Nutrition Labeling and Nutrient Content Revision" (hereinafter identified as the "supplementary nutrition labeling proposal") to bring its earlier mandatory nutrition labeling and RDI/DRV proposals into conformity with the 1990 amendments. In addition to the changes required by the legislation, FDA is proposing some changes to assist the implementation of the final regulations and to help clarify the earlier proposals. With respect to fat and fatty acids, the agency is proposing that they be declared in increments of ½ g rather than 1 g.

II. Scientific Background to Proposed Action

A. Overview

The Surgeon General's Report (Ref. 5) and the NAS report "Diet and Health, Implications for Reducing Chronic Disease Risk" (Ref. 6) considered the evidence on the effect of diet on an individual's health. One of the main conclusions from these reports is that consumption of diets high in fat, saturated fat, and cholesterol is associated with increased risks of developing certain chronic diseases. These reports recommend that Americans reduce their consumption of these substances in their diets.

Given the significance of dietary intake of fat, saturated fatty acids, and cholesterol, FDA is seeking ways to assist consumers in modifying their diets to reduce their intake of these food components. One way to do so is to ensure that the food label provides information on the fat, fatty acid, and cholesterol content of the food. To this end, FDA is issuing proposed nutrition labeling regulations that will require that most foods bear nutrition labeling that discloses the quantitative amounts per serving of total fat, saturated fat, and cholesterol as well as the number of calories derived from fat.

In this document, FDA is proposing to provide for the use of descriptor (nutrient content) claims on food labels or labeling to describe the fat, fatty acid, and cholesterol content of the food. This document does not, however, address whether it is possible to use the food label to communicate explicit health-related information, nor does it address what type of health information, if any, on dietary fat, fatty acids, and cholesterol would be appropriate for food labeling. FDA is addressing these issues in the ongoing rulemaking proceeding on "Health Messages and Label Statements" (see proposed rule, 55 FR 5176, February 13, 1990).

The following discussion describes dietary fats and the scientific background for this proposal to define fat and fatty acid nutrient content claims. Similar information on cholesterol can be found in the 1986 proposed rule (51 FR 42584).

B. Description of Dietary Fats

Fats provide the most concentrated source of energy in the diet. Each gram of fat furnishes approximately nine calories, while carbohydrates and protein furnish approximately four calories per gram. (FDA is using the term "calories" throughout this document rather than the more precise "kilocalories" or "energy" because the term "calories' is more readily understood by consumers.) The major sources of fat in the American diet are meat, poultry, and fish; dairy products; and the category of foods referred to as ("fats and oils" Ref. 5, p. 10).

Most fats occur in food as triglycerides, which, upon hydrolysis (which occurs during the digestion of fats), yield fatty acids and glycerol. A fatty acid is composed of a carboxylic acid group attached to a chain of carbon atoms. Most carbon atoms in the chain have two hydrogen atoms attached to them. However, sometimes two adjacent carbon atoms each have only one hydrogen atom attached to them instead of two and are joined together by what is called "a double bond."

The number of carbon atoms joined by double bonds determines the degree of unsaturation of a fatty acid. Fatty acids with no double bonds are saturated, those with one double bond are monounsaturated, and those with two or more double bonds are polyunsaturated. The fatty acids commonly found in foods are usually composed of an even number of carbon atoms, usually 12 to 22, and contain from 0 to 6 double bonds.

The fatty acid composition of fats and oils may be modified through a process

known as "hydrogenation," in which double bonds gain hydrogen atoms and become single bonds. Fats and oils are hydrogenated to reduce their susceptibility to rancidity and to change the fat from a liquid to a solid form. The degree of hydrogenation can vary considerably. The composition of the original fat or oil and the degree of hydrogenation affect the fatty acid composition of the final product.

Complete hydrogenation of a fat or oil results in a solid fat containing only saturated fatty acids. More commonly, a fat or oil is partially hydrogenated. Hydrogenation reduces the content of polyunsaturated fatty acids and increases the content of monounsaturated and saturated fatty acids. Partial hydrogenation of fats or oils may produce additional changes in the chemical structure of the fatty acids, such as changes in the location of double bonds along the carbon chain and in the formation of "trans" double bonds, which have a geometric configuration different from that which occurs predominately in nature.

All dietary fats consist of a mixture of saturated, monounsaturated, and polyunsaturated fatty acids. In general, animal-derived fats contain a higher proportion of saturated fatty acids than fats or oils derived from plants. The latter generally contain more monounsaturated and polyunsaturated fatty acids. There are some exceptions to this generalization. Coconut oil and palm kernel oil, for example, contain a high proportion of saturated fatty acids even though they are derived from plants, and some fish oils are good sources of polyunsaturated fatty acids (Ref. 5, p. 57). Furthermore, some hydrogenated vegetable oils that are used in processed foods as alternatives to animal fat or coconut or palm kernel oil may contain high levels of saturated fatty acids.

In regard to the effect of dietary fats on serum cholesterol levels, the amount of saturated fatty acids present in the final food product is more important health information than the source of the fat or oil (Ref. 7).

C. Diet and Chronic Diseases

Although much remains to be learned about the impact of diet on chronic disease risk, the overall evidence supports a relationship between certain dietary patterns and chronic diseases. As stated in the Surgeon General's Report:

High intake of total dietary fat is associated with increased risk for obesity, some types of cancer, and possibly gall bladder disease. Epidemiologic, clinical, and animal studies provide strong and consistent evidence for the relationship between saturated fat intake, high blood cholesterol, and increased risk for coronary heart disease * * *. Excessive saturated fat consumption is the major dietary contributor to total blood cholesterol levels. Dietary cholesterol raises blood cholesterol levels, but the effect is less pronounced than that of saturated fat * * *.

Dietary fat contributes more than twice as many calories as equal quantities (by weight) of either protein or carbohydrate, and some studies indicate that diets high in total fat are associated with higher obesity rates. In addition, there is substantial, although not yet conclusive, epidemiologic and animal evidence in support of an association between dietary fat intake and increased risk for cancer, especially breast and colon cancer. Similarly, epidemiologic studies suggest an association between gallbladder disease, excess caloric intake, high dietary fat and obesity.
(Ref. 5, p. 10).

The NAS report similarly stated the general conclusion that "total amounts and types of fats and other lipids in the diet influence the risk of atherosclerotic cardiovascular diseases and, to a less well-established extent, certain forms of cancer and possibly obesity." The report went on to state that, "Intake of total fat per se, independent of the relative content of the different types of fatty acids, is not associated with high blood cholesterol levels and coronary heart disease," but rather that, "saturated fatty acid intake is the major dietary determinant of the serum total cholesterol and LDL cholesterol levels in populations and thereby of coronary heart disease risk in populations." (Ref. 6). On the basis of the current scientific evidence, both reports recommend that individuals reduce their consumption of fat (especially saturated fat) and cholesterol.

Coronary heart disease (CHD) remains the leading cause of death in the United States today. The causes of CHD are multifactorial. Evidence from animal and human studies and from epidemiologic surveys continues to accumulate, implicating among other factors high blood cholesterol, high blood pressure, and cigarette smoking as causative agents in the development of atherosclerosis. Atherosclerosis, in turn, leads to narrowing of the arteries and development of CHD. The scientific evidence supporting these conclusions has been extensively reviewed in the Surgeon General's Report (Ref. 5) and the NAS report (Ref. 6). In regard to blood cholesterol levels, the Surgeon General's Report states:

> An extensive body of clinical evidence supported by animal, epidemiologic, and metabolic studies has established the relationship between high blood cholesterol and increased CHD risk. The relationship is strong, continuous, and graded.
> (Ref. 5, p. 86.)

The Surgeon General's Report also states:

> Numerous expert bodies have examined the evidence relating diet to CHD and its implications for public health. Although there are many determinants of blood cholesterol levels, no modifiable factor has been shown to influence cholesterol and low-density lipoproteins more than diet.

Accordingly, many expert health organizations have made recommendations for modifying dietary intake of fat, fatty acids, and cholesterol for the purpose of improving the public health. These recommendations are summarized as follows:

1. *The Surgeon General's Report:* Reduce consumption of fat (especially saturated fat) and cholesterol. Choose foods relatively low in these substances, such as vegetables, fruits, whole grain foods, fish, poultry, lean meats, and low-fat dairy products. Use food preparation methods that add little or no fat (Ref. 5).

2. *The NAS Report:* Reduce total fat intake to 30 percent or less of calories, reduce saturated fatty acid intake to less than 10 percent of calories, and the intake of cholesterol to less than 300 mg daily (Ref. 6).

3. *U.S. Department of Health and Human Services and U.S. Department of Agriculture in "Nutrition and Your Health, Dietary Guidelines for Americans":* Choose a diet low in fat, saturated fat, and cholesterol (Ref. 8).

4. *The National Cholesterol Education Program (NCEP) Report of the Expert Panel on Population Strategies for Blood Cholesterol Reduction (Population Panel):* Healthy Americans should consume less than 10 percent of total calories from saturated fatty acids, an average of 30 percent of total calories or less from all fat, less than 300 mg of cholesterol per day, and energy (calorie) levels needed to reach or maintain a desirable body weight (Ref. 9).

5. *Report of the NCEP Expert Panel on Detection, Evaluation and Treatment of High Blood Cholesterol in Adults:* For adults with borderline to high blood cholesterol, the NCEP recommended two diets to assist in lowering high blood cholesterol levels. In the step-one diet, less than 30 percent of total calories are to come from dietary fat, with less than 10 percent coming from saturated fatty acids, up to 10 percent

from polyunsaturated fatty acids, and 10 to 15 percent from monounsaturated fatty acids. In addition, cholesterol intake is to be less than 300 mg per day. The step-two diet (for persons requiring greater dietary modifications to lower serum cholesterol) differs in that saturated fatty acid intake is to be less than 7 percent of total calories and cholesterol less than 200 mg per day (Ref. 10).

6. *American Heart Association:* Calories derived from fat should be less than 30 percent of total caloric intake, calories derived from saturated fat should be less than 10 percent of calories, and the daily cholesterol intake should be less than 300 mg (Ref. 11).

7. *American Medical Association (AMA):* Persons with hypercholesterolemia (high serum cholesterol) and hypertriglyceridemia (high serum triglycerides) should consume a diet in which no more than 30 to 35 percent of calories are derived from fat, in which less than 10 percent of calories are from sources of saturated fat, and in which there is less than 300 mg of cholesterol per day (Ref. 12). While these recommendations were originally made in 1983, the AMA currently supports the NCEP recommendations.

8. *Inter-Society Commission on Heart Disease Resources:* Reduce dietary cholesterol to no more than 250 mg per day, reduce total fat intake to less than 30 percent of calories, and adjust fat intake to provide no more than 8 percent of calories from saturated fat (Ref. 13).

9. *World Health Organization Expert Committee on Prevention of Coronary Heart Disease:* In countries with a high incidence of CHD, such as the United States, blood cholesterol levels should be lowered through progressive changes in eating patterns, including consumption of under 300 mg of cholesterol per day and less than 10 percent of energy intake as saturated fat (Ref. 14).

III. Provisions of the Proposed Regulation—Use of Defined Terms and Comparative Statements

A. Introduction

1. Legal Basis

FDA is proposing to define terms that describe the fat, fatty acid, and cholesterol content of food, to provide for the proper use of these terms, and to provide for the use of comparative claims regarding the level of these substances in food labeling. FDA has authority to take these actions under sections 201(n), 403(a), 403(r), and 701(a) of the act (21 U.S.C. 321(n), 343(a), 343(r), and 371(a)). Those sections authorize the agency to adopt regulations that prohibit labeling that is false or misleading in that it fails to reveal material facts with respect to consequences that may result from use of the food and that uses terms to characterize the level of any nutrient in a food that have not been defined by regulation by FDA.

Because the consensus reports cited above suggest that consumers limit their dietary intake of fat, fatty acids, and cholesterol, and because comments to the 1989 ANPRM and testimony at FDA's public hearings on labeling show that consumers are concerned about, and wish to reduce their dietary intake of these substances, it is important that label statements not convey a misleading impression about the fat, fatty acid, or cholesterol content of a food. Without clear definitions of the terms that describe the levels of these nutrients in food, manufacturers could use a term like "low fat" on products that vary widely in fat content. Inconsistent use of the same term on various products could only lead to consumer confusion and nonuniformity in the marketplace. To ensure that consumers are not misled and are given reliable information, Congress found, and FDA agrees, that it is appropriate for the agency to establish specific definitions to standardize the terms used by manufacturers to describe the fat, saturated fatty acid, and cholesterol content of foods. FDA is proposing to do so in this document.

2. Organization of Regulations

As discussed in the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register**, FDA is proposing to reorganize part 101 of its regulations to add Subpart D—Specific Requirements for Nutrient Content Claims. In doing so, FDA is proposing to redesignate current § 101.25 *Labeling of foods in relation to fat and fatty acid and cholesterol content* as § 101.62 *Nutrient content claims for fat, fatty acid, and cholesterol content of foods.* This change will allow this section on fat, fatty acid, and cholesterol content claims to be grouped with the other descriptor definitions in new subpart D.

The companion document on nutrient content claims also proposes to add a new section, § 101.13 *Nutrient content claims—general principles*, which sets forth general rules for all nutrient content claims. FDA is proposing in § 101.62(a)(2) to require that fat, fatty acid, and cholesterol content claims comply with the provisions of § 101.13 as well as § 101.62.

Among the most significant of the proposed general provisions are §§ 101.13(g) and (h), which set forth the requirements for the statement that, under the act, must accompany any nutrient content claim. Pursuant to section 403(r)(2)(B) of the act, the labels or labeling of foods that bear nutrient content claims must contain the following statement that refers the consumer to the nutrition label: "See _____ for nutrition information." Under section 403(r)(2)(B)(i) of the act, the blank must identify the panel of the package on which the nutrition label is located. Proposed § 101.13(g) reflects this requirement.

Proposed § 101.13(h) provides, in accordance with section 403(r)(2)(B)(ii) of the act, that the statement must also identify any nutrient that is present in the food at a level that increases to persons in the general population the risk of a disease or health-related condition that is diet-related. The section also proposes to define specific levels of fat, saturated fat, cholesterol, and sodium that present such a risk.

Thus, some foods that meet the definition for "low fat," for example, contain cholesterol at levels that require identification of this nutrient (proposed in § 101.13(h) as levels of more than 45 mg of cholesterol per serving or per 100 g of food). Many species of fish and shellfish are examples of such foods. To refer consumers to the cholesterol content of these foods, the agency is proposing in § 101.13(h) that the label of such foods bear, in immediate proximity to the "low fat" claim, the following statement: "See _____ for information on cholesterol and other nutrients," with the blank filled in with the identity of the panel of the label where the nutrition information is located.

For other general provisions, the reader is referred to the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register.** Consistent with the discussion in that document, to ensure that foods that bear fat, saturated fat, and cholesterol claims bear nutrition labeling, FDA is proposing to require such labeling as a general requirement in proposed § 101.62(a)(3).

3. Serving Size to Evaluate Nutrient Content Claims

FDA proposed in § 101.12(f) of the 1990 serving size proposal (55 FR 29517) that for any container with more than one serving the proposed standard serving size would be used to determine the appropriateness of a nutrient content claim, such as "cholesterol free." For single-serving containers containing 100 percent or less of the standard serving, the agency proposed to evaluate the

label claim based on the standard serving size. However, for single-serving containers containing more than 100 percent, but 150 percent or less of the standard serving, the agency proposed to evaluate the claim on the basis of the entire content of the package.

A majority of comments on FDA's proposal supported the proposed basis for evaluation of nutrient content claims. However, many food industry and trade organization comments objected to the proposed evaluation criteria. Such comments generally stated that the standard serving size, not the package content, should be used to evaluate descriptor claims on all types and sizes of packages. Manufacturers pointed out that under the 1990 proposal on serving size, the same food product that could be labeled as "low sodium" on the basis of the standard serving size might not qualify for a "low sodium" claim when packaged in a single-serving container containing between 100 percent and 150 percent of the standard serving. For example, an 8 fluid ounce container of skim milk containing 126 mg of sodium would meet the criteria for a "low sodium " claim, but a 10 fluid ounce container of the same milk containing 158 mg of sodium would not.

Because of the complexity of the issues with respect to serving size and the need to obtain further public comment on the impact of the 1990 amendments and the IOM report (Ref. 4) on this subject, FDA announced a public meeting to discuss issues related to serving size determination (56 FR 8084, February 26, 1991). In the notice of the public meeting, FDA raised the question of whether the discrepancies in the use of nutrient content claims on food products would be confusing and asked for data to support any views presented. The public meeting was held on April 4, 1991, and provided opportunity for both oral and written comments.

In comments, a manufacturer suggested that FDA establish reference serving sizes, and that both the reference serving size and the serving size declared on the label be required to be used to evaluate the compliance with FDA criteria for the nutrient content claims. The agency believes that this suggestion is a reasonable approach to regulating the use of nutrient content claims not only on single-serving containers but also on all other products when the serving size declared on the label differs from the reference standard (e.g., products in discrete units such as muffins). Therefore, in proposed § 101.12(b) in the agency's reproposal on serving sizes published elsewhere in this issue of the **Federal Register**, FDA has set forth reference amounts customarily consumed per eating occasion (reference amounts) for 131 food product categories. In accordance with provisions of the 1990 amendments that require label serving sizes to be expressed in common household measures, proposed § 101.9(b)(2) in the same document provides procedures for manufacturers to use in converting the reference amounts, which generally are in metric measures, to label serving sizes most appropriate for their specific products.

In proposed § 101.12(g), FDA is proposing that, if the serving size declared on the product label differs from the reference amount listed in proposed § 101.12(b), both the reference amount and the serving size declared on the product label must be used to determine whether the product meets the FDA criteria for nutrient content claims as set forth in 21 CFR part 101, subpart D.

Consistent with proposed § 101.12(g), FDA is proposing for the subject fat, fatty acid, and cholesterol claims (as well as for all other nutrient content claims discussed in the companion document on nutrient content claims) that all per serving criteria (e.g., less than 2 mg of cholesterol per serving for "cholesterol free" claims) will apply to the serving size declared on the product label and, where the labeled serving size and the reference amount differ, to the reference amount as well. Therefore, taking the preceding example of skim milk, the proposed reference amount customarily consumed for all beverages is 240 milliliters which is equivalent to 8 fluid ounces. When considering the 8 fluid ounce container, the reference amount and the labeled serving size are the same. Therefore, because 8 fluid ounces of skim milk contain 126 mg of sodium and the definition for "low sodium" is an amount of 140 mg or less, the container could bear a "low sodium" claim.

However, when considering the 10 fluid ounce container, the labeled serving size is larger than the reference amount. Ten fluid ounces of skim milk contain 158 mg of sodium, an amount exceeding the definition for "low sodium." Therefore, while the amount of sodium in the reference amount of skim milk is within the definition, the amount of sodium in the labeled serving size is not. Hence, if this proposed rule is adopted, the 10 fluid ounce container could not bear a "low sodium" claim. While acknowledging the apparent contradiction this difference in treatment causes, FDA tentatively concludes that it would be misleading to allow claims based only on the reference amount because, particularly with single-serving containers, the consumer is expected to consume the entire labeled serving size. Likewise, it could also be misleading to allow claims based only on the labeled serving size, because this could cause manufacturers to attempt to manipulate serving sizes, even within the proposed constraints.

In the regulations in subpart D of 21 CFR part 101, the agency will describe the applicability of these dual criteria to the quantitative amounts in the proposed regulations as per reference amount customarily consumed and "per labeled serving size." Rather than complicating the discussions concerning proposed quantitative amounts in this preamble, however, FDA will abbreviate "per reference amount customarily consumed and per labeled serving size" as "per serving."

B. Total Fat Claims

1. "Fat free"

a. *Definition.* In response to the 1989 ANPRM, FDA received a few comments on the definition of the term "fat free." Most of these comments recommended that "fat free" be defined as 0.5 g or less per serving.

The agency finds merit in these comments and is proposing in § 101.62(b)(1)(i) to define the term "fat free" ("free of fat," "no fat," "zero fat," "nonfat," "trivial source of fat," "negligible source of fat," or "dietarily insignificant source of fat") to include foods that contain less than 0.5 g of fat per serving.

FDA has discussed in the companion document on nutrient content claims, published elsewhere in this issue of the **Federal Register**, its general approach to defining "free" levels of nutrients. This approach is that the level of a nutrient that is described as "free" should be at or near the reliable limit of detection for the nutrient in foods and should be dietetically trivial or physiologically inconsequential.

In the case of analytical methodologies for fat, 0.5 g of fat per serving defines a level of fat in food that is at or near the reliable limit of detection of fat in food. The actual limit of detection of fat in food varies with different food products. However, 0.5 g represents the limit of quantitation in essentially all foods (i.e., analytical precision and accuracy below this amount is difficult). In proposed § 101.9(c)(4) of the supplementary nutrition labeling proposal, the agency is proposing that less than 0.5 g of fat

could be declared as "0" in nutrition labeling.

In addition, the agency has selected 0.5 g per serving as the definition for "fat free" because it believes that a cutoff of 0.5 g is low enough compared to the DRV for fat, which is 75 g, to be considered dietetically trivial or physiologically inconsequential. For example, a person consuming 16 to 20 servings per day (Refs. 15 through 17) of food containing 0.5 g of fat per serving would consume only 8 to 10 g of total fat per day, or no more than 90 calories from fat per day and (for a diet of 2,350 calories) less than 4 percent of calories from fat. This level of fat is insignificant compared to the recommended level of 30 percent or less of calories from fat in the diet (Refs. 6, 9 through 11, and 13).

FDA established a policy of using "free" as a descriptor of physiologically insignificant levels of a food component when it adopted the regulation for sodium nutrient content claims (49 FR 15510, April 18, 1984). The agency has received comments that contend that the term "fat free" will mislead consumers into believing that food so labeled is completely without fat. However, the agency believes that no harm will result from any misunderstanding caused by the use of this term on foods that meet the definition because, as discussed above, foods containing less than 0.5 g of fat per serving contain a trivial amount of fat compared to the total dietary intake of fat for any particular individual. FDA is proposing to express this requirement on a per serving basis because it believes that consumers are most familiar with nutrient content claims being defined in this manner. The agency has used this basis in defining terms that describe the calorie, sodium, and cholesterol content of foods and is therefore proposing an approach that is consistent with that used by the agency in the past. Comments that the agency has received in response to the 1989 ANPRM and public hearings also supported continued use of serving sizes in the definition of nutrient content claims, as did the IOM report (Ref. 4).

The agency is not proposing a second criterion based on the amount of fat per 100 g for the definition of "free" because the first proposed criterion for this nutrient requires that the food contain such a trivial level of fat from a public health perspective that even frequent consumption in large amounts of foods that bear a "fat free" descriptor would not affect in any meaningful way the overall fat level in the diet.

b. *Use of "fat free" on products with added fat.* The agency is aware that the claim "fat free" appears on the labels of certain products to which small amounts of fat have been deliberately added as an ingredient. For example, some products that declare a fat content of "zero" and that bear the claim "fat free" list soybean oil as an ingredient. The agency has received letters expressing confusion about this type of labeling. The Minnesota State Attorney General, writing on behalf of eight other State attorneys general, has written to the agency to express their view that such labeling would be misleading to consumers (Ref. 18).

In response to these concerns, the agency is proposing in § 101.62(b)(1)(ii) to add a second criterion to the definition of "fat free" to disallow the use of the term on the labels of products to which fats or oils have been added as ingredients. Without this criterion, it would be possible for a food that meets the quantitative criterion for the "fat free" descriptor (i.e., contains less than 0.5 g of fat per serving) to have a small amount of fat or oil added as an ingredient.

The claim "fat free" is a representation that the food is free of fat. The agency believes that this representation can be made in good faith if the food inherently contains very small amounts of fat (i.e., less than 0.5 g per serving) because the food does not contain a dietarily significant amount of fat. Such a representation cannot be made in good faith, however, if the manufacturer intentionally adds a fat or oil to the food. In such circumstances, even though the fat might not be dietarily significant, it is obvious from reading the ingredient statement that it has been added, and, thus, FDA tentatively concludes that representing the food as free of fat would cause confusion and be false and misleading under sections 201(n) and 403(a) of the act. The agency solicits comments on this tentative conclusion.

As an alternative approach, it would be possible to allow "free" claims even though the nutrient is added, if the label includes a disclosure statement in association with the claim acknowledging the addition of the nutrient. In order for the claim to not be misleading, such a disclosure statement would need to be prominent and immediately adjacent to the claim each time it is made. Such a disclosure might state, "An insignificant amount of fat has been added to this product as an ingredient." This approach was suggested by the Minnesota Attorney General as an alternative if FDA determined that it was not feasible to prohibit nutrient free claims on products that contained a very small amount of a nutrient added as an ingredient (Ref. 18). The agency solicits comments on whether nutrient free claims should be allowed on products that contain a very small amount of a the nutrient as an ingredient if such products provide an appropriate disclosure statement and, if so, what such a disclosure statement should be. The agency points out, however, that although, under this proposal, a product would not be allowed to call itself "free" of a nutrient if a manufacturer intentionally added the nutrient to the food as an ingredient, the label could make other positive, true, and nonmisleading statements about the product such as how little of the nutrient is actually in the product. For example, if a manufacturer found that it was necessary to add a very small amount of fat to a product to assure that the product was palatable to consumers, the label could make a statement reflecting the amount of fat in the product provided that that amount of that nutrient could meet the definition for "low fat." Such a statement might be "contains less that ½ gram of fat per serving," or if accurate, "99 percent fat free." This labeling is consistent with § 101.13(i) which states that, in addition to statements about the percent of a vitamin or mineral in a food relative to the RDI, the label or labeling of a product may contain a statement about the percent or amount of a nutrient that implies that the food is high or low in a nutrient if the food actually meets the definition for either "high" or "low" as defined for the nutrient that the label addresses.

In addition, the label or labeling of a product may bear a variety of other positive statements about the product such as the product is "low," or in the case of sodium, "very low," in the nutrient or that the amount of the nutrient in the food is reduced, if that is the case, or that there is less of the nutrient in the product than some in another product.

c. *Foods inherently fat free.* Section 403(r)(2)(A)(ii) states that absence (i.e., "free") claims may not be made for foods unless the nutrient for which the claim is made is usually found in the food, or in a food that substitutes for the food (see proposed § 101.13(d)), or the Secretary allows such a claim based on a finding that the claim would assist consumers to maintain a healthy diet. Thus the act gives the agency the authority to limit "free" claims on foods inherently free of a nutrient.

However, FDA believes that highlighting "fat free" foods can help consumers maintain healthy dietary practices whether the food is inherently free of fat or is processed to be that way. Many respondents to FDA's

consumer surveys have reported difficulty in understanding the quantitative information presented in nutrition labeling (Ref. 19). Furthermore, FDA surveys have shown that consumers want nutrient content claims and find them useful in making food selections. Supermarket studies by FDA have shown that shoppers are using descriptive terms that highlight positive nutritional attributes (such as "fat free") to make food purchase selections (Refs. 20 and 21). In addition, they help to educate consumers on the intrinsic properties of foods. FDA believes that the definitions established in this proposed rule respond to consumers' needs. Therefore, FDA has tentatively concluded that it is not necessary to limit "fat free" claims to foods in which fat is usually present or that substitute for foods that usually contain fat.

However, the agency believes that the unqualified use of the term "free" on foods that are inherently free of a nutrient can be misleading because such terminology would imply that the food has been altered to reduce the nutrient as compared to other foods of the same type. Accordingly, FDA is proposing in this document (§ 101.62(b)(1)(iii)) and in the companion document on nutrient content claims (§ 101.13(e)) to require that if a food is free of a nutrient without the benefit of special processing, alteration, formulation, or reformulation to lower the content of the nutrient, it must refer to all foods of that type and not merely to the particular brand to which the labeling is attached. For example, many fruits and vegetables are foods that would meet the definition for the term "fat free." Therefore, if the agency adopts this policy, broccoli that bears a "fat free" descriptor would have to bear labeling such as "broccoli, a fat free food."

This requirement is consistent with the general policy on "free" and "low" claims discussed in the preamble to the final rule on sodium labeling in relation to sodium claims (49 FR 15510 at 15517) and proposed in § 101.25(a)(2)(i) and (a)(2)(ii) of the tentative final rule for both "free" and "low" cholesterol claims (55 FR 29456). The agency believes that this requirement is necessary to prevent the consumer from being misled by an implication that a particular food has been altered to lower its fat, when, in fact, all foods of that type are naturally free of, or low in, that nutrient.

FDA is aware that the effect of this proposed action will be to allow "free" claims on foods that do not usually contain the nutrient (e.g., "Brand A soft drink, a fat-free food"). However, because of the importance of highlighting "fat free" foods, the agency believes that this course is the appropriate one. FDA specifically requests comments on this aspect of its proposal.

Therefore, FDA is proposing in § 101.62(b)(1) to allow "fat free" claims on all foods that contain less than 0.5 g of fat per serving and contain no added fat or oil and, in § 101.62(b)(1)(iii), to require that "fat free" claims on foods that are inherently "fat free" disclose that fat is not usually present in the food.

2. "Low Fat"

a. *Definition.* Most of the comments on the 1989 ANPRM that dealt with fat nutrient content claims favored a single, uniform maximum cutoff ranging from 2 to 5 g of fat per serving for all food categories for defining the term "low fat."

The comments favoring 5 g of fat per serving for all food categories were primarily from representatives of the dairy industry, who suggested that the cutoff for "low fat" be consistent with the cutoff in the food standard for lowfat milk (21 CFR 131.135). This standard, which was promulgated in 1973, allows milk containing 0.5-, 1-, 1.5- or 2-percent milkfat to be named "lowfat milk." Two percent milkfat in an 8-fluid ounce serving equates to 5 g of fat.

The agency, however, has derived its proposed definition for "low fat" and the synonyms "low in fat," contains a small amount of fat, "low source of fat," or "little fat" from the proposed general principles for nutrient content claims that appear in the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register**. Under these general principles, the agency is defining a "low" claim for a nutrient that is ubiquitous in the food supply as an amount equal to 2 percent of the DRV for the nutrient. FDA has selected 2 percent as the starting point based on its historical use of 2 percent of the U.S. RDA as a measurable amount of a nutrient in a food (§ 101.3(e)(4)(ii)).

To arrive at a defined value for "low" when a nutrient is not ubiquitous, the agency is proposing to increase the 2 percent amount to adjust for the nutrient's uneven distribution in the food supply. This adjustment recognizes the practice of dietary planning in which a person consumes in a day a reasonable number of servings of foods labeled as "low," balanced with a number of servings of foods that do not contain the nutrient in question and a small number of servings of foods that contain the nutrient at levels above the "low" level, and is still able to stay comfortably within the guidelines of the various dietary recommendations. This adjustment to reflect the nutrient's distribution in the food supply has the effect of permitting a wider variety of foods to be labeled as "low" than would be possible if the 2 percent of the DRV standard was used generally to define "low."

With respect to fat, current dietary guidelines (Refs. 6, 8, and 9) recommend that a person consume a maximum of 30 percent of calories from fat, which in a diet of 2,350 calories per day would allow for consumption of a maximum of 75 g of fat per day. This value has been proposed as the DRV for fat (55 FR 29476). Two percent of this proposed DRV is 1.5 g.

The agency is not proposing 1.5 g as the cutoff of a "low fat" claim, however, because fat is not ubiquitous in the food supply. For instance, very little fat is found in most fruits, vegetables, and grains. Because fat is not ubiquitous and yet is found in more than a few food categories, FDA tentatively concludes that an appropriate upper limit for a "low fat" claim should be set at two times 2 percent of the DRV, or 3 g per serving. The agency tentatively concludes that this amount is a reasonable definition for "low fat" because an average level of 3 g in 16 to 20 servings of food per day (balancing the number of foods that do not contain fat with those that contain higher levels of fat to yield an average of 3 g of fat per serving) would supply 48 to 60 g of fat daily, comfortably within the DRV of 75 g of total fat. Therefore, the agency is proposing in § 101.62(b)(2)(i) that a "low fat" food contain 3 g or less of fat per serving.

It should be noted that in deciding whether a food meets the criteria for "low fat" (and all other nutrient content claims except "free"), FDA considers the per serving criterion to pertain to the amount that is appropriately declared in nutrition labeling under § 101.9 rather than the amount that is actually present in the food product. Therefore, a food may meet the "low fat" criterion of "3 g or less fat per serving" even though it actually contains slightly more than 3 g of fat per serving. This anomaly occurs because of the rounding rules that FDA is proposing in the nutrition labeling regulations. Proposed § 101.9(c)(4) states that fat is to be expressed to the nearest 1/2 g. Accordingly, if FDA adopts that provision in the final nutrition labeling regulations, a food containing up to 3.24 g of fat would declare the level of fat as 3 g in nutrition labeling and would thus meet the criterion of "3 g or less fat per serving."

This anomaly will not occur with "free" claims because FDA is proposing to define them as "less than X amount" rather than "X amount or less." Because the integer is not included in the definition, FDA is proposing not to allow rounding above that amount.

b. *Need for criterion based on weight.* The agency is proposing in § 101.62(b)(2)(i) that a "low fat" food would have to contain 3 g or less fat per 100 g as well as per serving. FDA has stated in the companion document on nutrient content claims that an additional criterion based on weight is needed in some cases to prevent claims from being misleading. For example, some nutrient-dense foods have small serving sizes. Although these foods would meet the "low fat" definition on a per serving basis, because they may be consumed frequently throughout the day, they could produce a substantial total daily intake of a nutrient like fat. Thus, the agency has tentatively concluded that a second density criterion is appropriate for "low fat" foods. A density criterion has been used in conjunction with "low calorie" claims since 1977 (see current § 105.66(c)(1)(ii)) and was proposed as part of the definition for "low cholesterol" in § 101.25(a)(2)(ii) of the tentative final rule for cholesterol nutrient content claims (55 FR 29456).

Examples of foods that do not meet the definition of "low fat" because they do not meet the serving and density criteria include semi-solid frozen dessert toppings (2.3 g of fat per serving but 25 g of fat per 100 g of the food) and thick vanilla shakes (10.4 g of fat per serving although only 3 g of fat per 100 g of the food).

The agency notes that the proposed criteria for the definition of "low fat" differ from the criteria of 2 g or less of fat per serving and 10 percent or less of fat on a dry weight basis that the agency in the past has advised those interested to infer from § 101.25(c)(1) as a definition of "low fat" (Ref. 2). Although the first criterion (3 g per serving) of the proposed definition is more lenient than past agency advice (2 g per serving), the second criterion (3 g per 100 g of food) makes the total number of foods that meet the proposed definition essentially equivalent to the total number of foods that met the criteria of 2 g or less of fat per serving and 10 percent or less of fat on a dry weight basis. The assortment of foods varies somewhat however. For instance, some of the foods that meet the proposed criteria and not the previous criteria include 1 percent lowfat milk, and some soups. Foods that would meet either "low fat" definition include most fruit and vegetables, certain fish, shellfish, soups, and a few types of bread and cereal. Foods that do not meet the proposed criteria that had met the previous criteria include some breads, cookies, cereals (particularly presweetened cereals), and dehydrated soups. FDA tentatively finds it is appropriate to no longer permit these foods to make "low fat" claims because, if they are consumed frequently, they could result in a substantial total daily intake of fat.

c. *Foods inherently "low fat."* Consistent with the discussion above for foods inherently fat free, the agency believes that the use of the term "low fat" on foods that are inherently low in fat can be misleading. Accordingly, FDA is proposing in § 101.62(b)(2)(ii) to require that "low fat" claims on foods that inherently meet the definition for "low fat" refer to all foods of that type and not merely to the particular brand to which the labeling is applied.

For example, frozen perch would inherently meet the definition for the term "low fat." Therefore, if the agency adopts proposed § 101.62(b)(2)(ii), a package of frozen perch would be labeled "frozen perch, a low fat food." This requirement is consistent with the general policy on "free" and "low" nutrient content claims proposed in § 101.13(e)(2), which is published elsewhere in this issue of the **Federal Register.**

d. *"Low fat" meal-type products.* FDA has discussed in the companion document on nutrient content claims the requests that the agency has received for definitions for nutrient content claims that can be used on labels and in labeling of meal-type products. It is apparent that the per serving criteria in the agency's proposed definitions for claims for individual food products are too restrictive to apply to these products.

In 1986, in an effort to establish nutrient content claims that would help consumers identify positive nutritional characteristics of meal-type products, the agency proposed as a guideline that a meal containing less than 100 mg of cholesterol could be described as a "low cholesterol meal." However, in its tentative final rule on cholesterol nutrient content claims, the agency withdrew from this position because there was no clear definition of the term "meal" and asked for further comment.

To meet this need, and based on a letter submitted by the Grocery Manufacturers of America, Inc. (GMA) (Ref. 22), FDA is proposing in § 101.13(l) in its companion document on nutrient content claims to define a "meal-type product" as a food that: (1) Makes a significant contribution to the diet (a) by providing at least 200 calories or (b) weighing at least 6 ounces, and (2) contains ingredients from 2 or more of the following four food groups: bread, cereal, rice, and pasta group; fruit and vegetable group; milk, yogurt, and cheese group; and meat, poultry, fish, dry beans, eggs, and nuts group, and (3) is represented as, or is in a form commonly understood to be, a breakfast, lunch, dinner, meal, main dish, entree, or pizza.

In its letter, GMA suggested that for meal-type products "low fat" be defined as 3.5 g or less fat per 100 g of food. FDA finds merit in setting nutrient content claims for meal-type products on the basis of the amount of the nutrient per 100 g rather than on the basis of the amount per serving and per 100 g as is done for individual foods. A review of meal-type products on the market (Ref. 23) shows that such a criterion would allow nutrient content claims on meal-type products that can be used in a diet that is consistent with dietary recommendations set forth in the Dietary Guidelines for Americans. However, FDA believes it would be beneficial and less confusing if it used the same quantitative amounts to qualify for nutrient content claims for meal-type products that it is proposing for individual foods. Such consistency would assist consumers and health professionals to be able to recall and to use these amounts. Accordingly, the agency is proposing in § 101.62(b)(3)(i) to provide that a "low fat" claim may be made for a meal-type product that contains 3 g or less total fat per 100 g of product. The agency is also proposing in § 101.62(b)(3)(ii) to provide for such claims on meal-type products that meet the criterion without special processing.

e. *Related issues.* The agency received a comment that urged the establishment of different cutoffs for "low fat" for different foods (i.e., varying the quantitative definition of "low fat" according to food category).

The agency rejects this comment. The use of different criteria for different food categories has several disadvantages that affect both consumers and the food industry. When different criteria are used for different categories of foods, consumers cannot use the nutrient content claims to compare products across categories and will likely find it difficult to use the descriptor in substituting one food for another in their diets.

Although an argument can be made that different criteria for different foods would permit consumers to 'dentify the

products with the lowest fat levels in each category, the agency believes that such a system would have a high potential for misleading the consumer about the fat content of foods. To identify the product that has the lowest fat content in a category does not mean that the product is low in fat. Furthermore, by having different criteria for different food categories, it would be possible that some foods that did not qualify to use the descriptor would have a lower fat content than foods in other categories that did qualify. This situation would contribute to consumer confusion and misunderstanding.

FDA has received many comments asking for increased consistency among nutrient content claims to aid consumers in recalling and using the defined terms. In addition, the IOM report recommended such consistency stating that "low sodium, for example, should have the same meaning, whether it is applied to soup, frozen peas, or meat" (Ref. 4, p. 251). Accordingly, the agency concludes that establishing different cutoffs for each descriptor according to food category would greatly increase the complexity of the task given to consumers who would use nutrient content claims to plan diets that meet dietary recommendations.

The agency wishes to emphasize that it is not necessary for persons to limit their diets solely to "low fat" and "fat free" foods. However, the agency believes that nutrient content claims identifying "low fat" and "fat free" foods will help the American public to attain the nutrition objective in "Healthy People 2000" to "reduce dietary fat intake to an average of 30 percent or less of calories and saturated fat intake to less than 10 percent of calories among people aged 2 and older" (Ref. 24). The current U.S. diet is reported, on average, to provide about 37 percent of calories from fat (Ref. 5).

The agency recognizes that the definition of "low fat" that it is proposing differs from the use of the term in certain standardized foods (e.g., 1½ and 2 percent lowfat milk). In 1987, the Center for Science in the Public Interest petitioned FDA to prohibit the use of the term "lowfat" on 2 percent milk because it contains 5 g of fat per serving and is 18 percent fat on a dry weight basis. The agency is not, however, proposing any action to resolve the inconsistency between the proposed definition and this food standard use of the term at this time. FDA believes that it would be inappropriate to act before a definition for "low fat" is finalized.

In addition, section 403(r)(5)(C) of the act, which was added by the 1990 amendments, specifies that nutrient content claims required by a standard of identity do not have to be defined by regulation or to comply with the definitions that FDA does adopt and do not require the referral statement required in § 101.13(g). The use of nutrient content claims in conjunction with names of standardized foods is outside the scope of this document and is addressed in a separate document in this issue of the **Federal Register**.

3. "Reduced Fat"

a. *Percent reduction.* Most of the comments received in response to the 1989 ANPRM on the term "reduced fat" supported FDA's general policy of requiring reductions that are nutritionally significant. Fewer than 15 comments offered suggestions on how much of a reduction should be required for a "reduced fat" claim. Most of those comments favored a reduction of at least 25 or 33 percent. The comments favoring 33 percent were primarily from cheese manufacturers, who stated that a greater reduction is not feasible for cheese.

The agency has considered these comments. However, it is proposing in § 101.62(b)(4)(i) that the term "reduced fat" ("reduced in fat" or "fat reduced") be used to describe a food that has been specifically formulated or processed to reduce its fat content by 50 percent or more, with a minimum reduction of more than 3 g per serving, from the food that it resembles and for which it substitutes (hereinafter referred to as "reference food").

The agency has tentatively selected the level of 50 percent for the minimum fat reduction to qualify for the "reduced fat" descriptor in accordance with general criteria for "reduced" nutrient content claims discussed in the preamble to the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register**. These general criteria take into consideration the level of reduction that would result in substantial reductions in the nutrient content of foods, the need for consistency of terms, and the technological feasibility of reducing levels of nutrients in foods. They also take into consideration the need for dietary changes relative to current intakes of nutrients.

FDA states in the companion document on nutrient content claims its belief that to make a reduced claim, there should be a substantial reduction in the amount of the nutrient present in the food. This belief is supported by comments that it received in response to the agency's 1989 ANPRM and public hearings. FDA believes that in defining the amount that constitutes a substantial reduction in a nutrient, it must take into consideration the distribution of the nutrient in the food supply. If a nutrient is ubiquitous, it will be consumed in a wide range of foods, and therefore, a dietary reduction in consumption of the nutrient can be spread out over all or most food categories. Thus, a smaller reduction on a food-by-food basis would be needed to achieve a substantial reduction in consumption of such a nutrient than would be needed if the nutrient were present in only some food categories. In the latter case, the nutrient would not be found in as many foods, and therefore, the reduction in the nutrient on a food-by-food basis would have to be greater to achieve a substantial dietary impact.

Fat is not ubiquitous throughout the food supply. Most fruit and vegetables and many grain products contain little or no fat. Reductions in the fat content of foods that are inherently low in fat are difficult and less cost effective than modifying foods that are high in fat. Therefore, to make substantial reductions in dietary fat intake, it is necessary to make significant reductions in foods containing high levels of fat.

Of the total number of foods on FDA's Regulatory Food Composition Data Base, approximately half are either fat-free or low-fat foods (Ref. 25). While this data base may not be representative of the entire food supply, it suggests that a large portion of the food supply is not amenable to a substantial reduction of fat content.

FDA notes that for calories, a nutrient that is ubiquitous in the food supply, the agency has determined that a percent reduction of 33 percent is necessary to justify a "reduced" claim. 21 CFR 105.66(d)(1)(i). Given this precedent, and the fact that at best only half the food supply is available to produce a substantial reduction in the fat content of the diet, FDA is proposing that a 50 percent reduction in the fat content of a food from the food that it is intended to resemble and to replace is necessary to justify a "reduced fat" claim. FDA notes that this level is consistent with the guidance that it has been giving the retail food industry for many years on "reduced fat" claims (Refs. 2 and 26).

The appropriateness of a 50 percent reduction is supported by calculations of the dietary changes needed to meet recommended intake levels. Dietary guidelines recommend reducing the intake of fat from foods from the current level in the average U.S. adult diet of approximately 37 percent of calories (Ref. 5) to 30 percent of calories (Refs. 6, 8, and 9). This change would require a

reduction in total fat intake of approximately 23 percent (Ref. 27). Since substantial reductions in fat can only be made in half of the foods in the food supply, it is reasonable to require that for foods making a "reduced fat" claim the fat content should be reduced by at least twice the reduction needed in the total diet in order to meet dietary recommendations (i.e., twice the 23 percent reduction, or 46 percent, which can be rounded to 50 percent).

As mentioned above, the agency's general criteria for "reduced" claims include consideration of the need for consistency of terms and the technological feasibility of achieving the specified levels of reduction. The continued use of the 50 percent criterion would allow not only for consistency with past guidelines but also with the values FDA is proposing for "reduced" claims for sodium, saturated fat, and cholesterol. In regard to technological feasibility, current technology has demonstrated that for many foods, including dairy products, a reduction in fat of 50 percent or more is readily achievable (Ref. 28).

The agency requests that interested persons submit comments on the proposed 50–percent reduction. Comments containing technical information supporting this or other suggested reduction levels will be particularly helpful.

b. *Absolute reduction.* Additionally, the agency is proposing, in § 101.62(b)(4)(i), a second criterion that would require a minimum absolute reduction of fat from the reference food that it replaces. As stated in the companion document on nutrient content claims, because the use of the term "reduced" is based on a percentage change rather than a specified amount per serving, the agency believes that an additional criterion specifying a minimum absolute amount of reduction for the nutrient is necessary to preclude manufacturers from making inconsequential changes in their products, which, given the initial low level of the nutrient, result in considerable reductions in terms of percent but not in terms of absolute amounts. For instance, without the inclusion of an additional criterion, a food containing only 4 g of fat per serving could be reformulated to contain 2 g of fat per serving and thereby qualify to use the term "reduced" when, in fact, the reduction of 2 g of fat cannot be considered either substantial or of nutritional significance.

In its companion document on nutrient content claims, FDA has tentatively concluded that, if a food is to make a consequential as well as a measurable reduction in a nutrient, the absolute reduction should not be less than that amount which is considered to be "low" on a per serving basis. A measurable amount of a nutrient is an amount greater than 2 percent of the label reference value (the amount defined in current § 101.3(e)(4)(ii) as a measurable amount of a nutrient). Two percent of the proposed DRV for total fat is 1.5 g (0.02 times 75 g). However, this amount is less than the amount of the per serving criterion for "low fat" (i.e., 3 or less g of fat per serving). Therefore, to bear a "reduced fat" claim, a food would have to have a minimum reduction that exceeds the per serving criterion for "low fat" (i.e., the reduction must be more than 3 g of fat per serving).

Guidelines or definitions for determining amounts of nutrients in foods that can be considered consequential or nutritionally meaningful are not available. However, as described in the companion document on nutrient content claims, FDA is proposing to use the definition for a "low" claim as the minimum amount of reduction in a nutrient in a food that would justify a "reduced" claim because a diet made up of exclusively "low" foods would contain a small but not insignificant amount of the nutrient. Total intake of the nutrient would not exceed the recommended DRV level, but would be as much as 50 percent or more of that level. Therefore, in considering consequential reductions for "reduced" foods, FDA has tentatively concluded that the amount per serving specified for "low" is a consequential amount of a nutrient, and that it is appropriate to define a consequential or nutritionally meaningful reduction in a nutrient as an amount that is not less than that amount considered to be "low" for the nutrient. Accordingly, FDA is proposing in § 101.62(b)(4)(i) that a "reduced fat" claim may be used on the label of a food in which the fat content has been reduced by more than 3 g of fat per serving, in addition to a reduction of fat of 50 percent or more from the reference food.

c. *Reference food.* As proposed in § 101.13(j)(1) of the companion document on nutrient content claims, the reference point against which a food can be said to contain a reduced level of a nutrient is either an industry-wide norm or the manufacturer's regular product. FDA is proposing to define an "industry-wide norm" in § 101.13(j)(1)(i) as a composite value weighted on a unit or tonnage basis according to a national market share of all foods of the same type as the food for which the claim is made. The agency is proposing to define a manufacturer's regular product in proposed § 101.13(j)(1)(ii) as a food that has been offered for sale to the public by the same business (or one entitled to use its name) and in the same locale on a regular basis for a substantial period of time.

These reference points were initially identified in comments to the agency's proposed regulation defining cholesterol content claims (51 FR 42584). The comments and FDA's response were discussed in the tentative final rule on the subject (55 FR 29456 at 29463). In the cholesterol rulemaking, FDA also proposed to allow a third reference point for a reduced claim, that of a similar product or class of products as found in a current, valid, composite data base. The agency has reconsidered permitting the use of this third reference point with "reduced fat" claims and now tentatively concludes that for a "reduced" claim a manufacturer should be required to compare the fat content of a food product either with its own product or with an actual market average as represented by the "industry-wide" norm for two reasons.

Foremost, the agency believes that the term "reduced" is a specific claim that requires that the comparison be made to products that are most like the product bearing the claim. A data base for a class of products will most likely include a spectrum of products that is too broad to support such a claim. For example, if a product is labeled as "reduced fat imitation bacon bits," it is claiming that it contains reduced fat when compared to other imitation bacon bits. If such a claim could be made on the basis of a data base of products similar to imitation bacon bits, the data base would likely include a range of products, including bacon. The imitation bacon bits could have reduced fat when compared to the data base but no less fat than other imitation bacon bit products. In such circumstances, the claim would clearly be misleading. Thus, FDA believes that comparison to a data base of similar products is not an appropriate basis for a "reduced fat" claim.

Moreover, particularly as a data base ages, the values in the base may no longer represent the nutrient composition of foods that are on the market. If, for example, all manufacturers have reduced the fat in their products, it would not be appropriate for an individual manufacturer to make a "reduced" claim against the higher value represented by the older average value. By requiring that the comparison be made against an

"industry-wide norm" or the manufacturer's regular product, the agency believes that this problem is minimized.

The agency is proposing in § 101.62(b)(4)(ii) that a food that bears a "reduced fat" claim be labeled in compliance with § 101.13(j)(2) as proposed in the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register**. Proposed § 101.62(b)(4)(ii) thus requires information in immediate proximity to the most prominent use of the claim of the extent (percent or fraction) that the fat is reduced, the identity of the reference food to which it is compared (e.g., "50 percent less fat than our regular brownie"), and quantitative information comparing the actual amount of fat in a serving of the food to the amount in the reference food (e.g., "Fat content has been reduced from 8 grams to 4 grams per serving").

The agency currently requires the comparative quantitative information and the identification of the reference food for reduced claims for sodium (§ 101.13(a)(4)) and calories (§ 105.66(d)(1)(ii)) to help prevent consumer misunderstanding. The agency believes that such information must be presented with a "reduced fat" claim for the same reason. The agency is proposing to add the requirement that the label or labeling declare the percent (or fraction) that fat and other nutrients have been reduced to give consumers additional information to evaluate the significance of the claim. This information will also allow consumers to more readily compare the levels of reduction in different foods making "reduced fat" claims. Thus, it is a material fact in light of the representations being made in the labeling.

In this and other situations where information is required to be in "immediate proximity" to a claim, the information must be immediately adjacent to the claim with no intervening material. This interpretation of "immediate proximity" is set forth in proposed § 101.13(g)(2) in the companion document on nutrient content claims and is required to prevent possible consumer misunderstanding.

Similarly, to identify the location in which the comparative information for relative claims is required, proposed § 101.13(j)(2)(ii) in the companion document defines "the most prominent location" as, in descending order: (1) A claim on the principal display panel (PDP) adjacent to the statement of identity, (2) a claim elsewhere on the PDP, (3) a claim on the information panel, or (4) a claim elsewhere on the label.

4. Comparative Claims

In proposed § 101.62(b)(5), the agency is providing for the use on food labels of comparative claims that use the term "less" to describe the fat content of the food expressed on a per serving basis. The agency recognizes that there are some foods that can achieve significant reductions in fat content but not reductions of 50 percent or greater. Because these foods do not attain a 50–percent reduction, they could not bear a "reduced fat" claim under this proposal. However, the agency believes that such foods should be able to be labeled with comparative statements using the term "less" that specify the extent of the fat reduction that has been made. For example, the label of a pound cake could bear the statement "40 percent less fat than our regular pound cake—fat lowered from 10 grams to 6 grams per serving."

To ensure that consumers are not misled by claims for reductions that are inconsequential, the agency is proposing in § 101.62(b)(5)(i) to permit a comparative statement on the label of a food only if the food has been formulated or processed to reduce its fat content by 25 percent or more, with a minimum reduction of more than 3 g of fat per serving. The requirement for a reduction of 25 percent or more is consistent with the agency's current policy for comparative claims for sodium (49 FR 15521, April 18, 1984) and proposed regulations for cholesterol (55 FR 29456). These positions were based on agency findings that products in which there has been a 25 percent or greater reduction will serve a useful role in the diet of those individuals who are attempting to limit their consumption of the nutrient. These criteria are also consistent with USDA guidelines that permit comparative fat claims for meat and poultry products when fat is reduced by 25 percent or more.

Improvements in food technology or other factors may make it practicable for manufacturers to measure reductions in nutrient content of less than 25 percent. The agency solicits comments, including data, on whether 25 percent is necessary as a minimum reduction requirement for all foods, or whether a lower level is possible.

However, FDA acknowledges that permitting comparative claims for foods with a percentage reduction of less than 25 percent may serve to facilitate consumers efforts to improve their diets if such claims are reliably made and the absolute reduction referred to by the comparative claim is nutritionally significant.

Consistent with "reduced fat" claims, the agency is also proposing to require an absolute reduction of more than 3 g of fat per serving from the reference food. While this criterion is new, FDA stated above its belief that an additional criterion specifying the absolute amount of reduction for the nutrient is necessary in order to preclude manufacturers from making inconsequential changes in a product, which, because of the initial low level of the nutrient, result in considerable reductions in terms of percent but not in terms of absolute amounts.

In determining the absolute reduction to be required, FDA considers that the amount must be both measurable in foods and nutritionally consequential. To meet these criteria, the amount would have to be, as discussed above with respect to "reduced fat" claims, not less than that amount that is considered to be "low." The amount defined as "low fat" is proposed to be 3 g or less per serving and per 100 g of food. Accordingly, FDA is proposing in § 101.62(b)(5)(i) that to bear a comparative claim for fat, an absolute reduction of more than 3 g of fat per serving is required.

In regard to reference foods, the agency is proposing in § 101.13(j)(1) in the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register** that for comparative claims, comparisons may be made to an industry-wide norm, to the manufacturer's regular product, or to a current, valid composite data base such as USDA's Handbook No. 8, "Composition of Foods, Raw, Processed, Prepared." The first two reference points are identical to those listed above for a "reduced" claim. The agency is proposing to permit the third reference point, as initially proposed in FDA's tentative final rule on cholesterol content claims (55 FR 29456 at 29463), for comparative claims because it believes that consumers will benefit from label statements that make legitimate, appropriate comparisons with similar classes of products, and that comparative claims do not necessarily need to imply a comparison to the product itself or a narrow range of similar products. For example, a label statement such as "My amaranth chips have 25 percent less fat than other chip snack foods" would be appropriate (if the amaranth chips also contain more than 3 g less of fat than the named class of products). In making this comparison, the manufacturer could rely on values from a current, valid data base for the

similar class of products. FDA specifically solicits comment on this point.

The agency is proposing in § 101.62(b)(5)(ii) that, as required in proposed § 101.13(j)(2), labels or labeling of a food for which a comparative claim is made must include a statement in immediate proximity to the most prominent such claim of the extent (percent or fraction) that the fat is reduced, the identity of the reference food to which it is compared, and the quantitative information comparing the actual amount of fat in a serving of the food to the amount in the reference food that it resembles and for which it substitutes. This requirement is identical to that for "reduced fat" claims discussed above. An alternative approach to comparative nutrient content claims is discussed in the companion document on general principles for nutrient content claims published elsewhere in issue of the Federal Register.

5. "____ Percent Fat Free" Claims

The agency received many comments to the 1989 ANPRM stating that "____ percent fat free" claims on foods are confusing and misleading. These comments suggest that many consumers do not understand this type of claim. Additional comments suggested that the term be prohibited.

The agency is proposing to prohibit the use of this claim in those circumstances in which it would be misleading and thus would misbrand the product. Claims that a food is "____ percent fat free" emphasize how close the food is to being free of fat, that is, to containing no fat. They imply that the food has a very small amount of fat in it, and that the food is useful in structuring a diet that is low in fat. The impression that the claim makes is misleading, however, if the food, despite the percentage calculation, contains a significant amount of fat.

On June 6, 1991, in a speech given at the 20th Anniversary Conference sponsored by the Center for Science in the Public Interest, the Commissioner outlined the agency's concerns about "____ percent fat free" claims:

> The high number—often 90 percent, 93 percent, and even 97 percent—linked with a desirable characteristic—"fat free"—leads people to conclude that the food itself promotes good health. It can also lead people to conclude that they can eat as much of it as they want. * * * We believe that this kind of assertion confuses and misleads consumers. Foods that derive a high percentage of their calories from fat should not be making low-fat claims.
> (Ref. 29)

The Commissioner called on industry to remove these claims from their products.

To ensure that the consumer is not misled by the term "____ percent fat free," and that, as the claim implies, the food does in fact contain only a small amount of fat, FDA is proposing in § 101.62(b)(6)(i) to require that such claims can only be made in foods that meet the criteria: (1) For "low fat" foods as proposed in § 101.62(b)(2) of this document (i.e., such foods would contain 3 g or less of fat per serving and per 100 g of food) or (2) for "low fat" meal-type products as proposed in § 101.62(b)(3) (i.e., such meal-type products would contain 3 g or less of fat per 100 g of product). The agency believes the claim would be misleading on a food or meal-type product that contains more than this low level.

The agency advises that a "____ percent fat free" declaration would be misleading if the number of g of fat in a serving of the food were not presented in conjunction with the claim. Under section 201(n) of the act, a food label is misleading if it fails to reveal facts material in light of the representations that are made on the label. Clearly, the actual amount of fat in a food is a material fact when a "____ percent fat free" claim is made. Therefore, in § 101.62(b)(6)(ii), FDA is proposing to require that the disclosure of the amount of total fat in a serving of food appear in immediate proximity to the most prominent such claim. In addition, given the potentially misleading nature of the claim, FDA believes that the quantitative disclosure of the amount of fat in a serving of the food should be in no less than one-half the size of the type of the "____ percent fat free" statement.

Finally, FDA is proposing in § 101.62(b)(6)(ii) that if the food contains less than 0.5 g of fat per serving (i.e., meets the criteria for "fat free"), the amount of fat may be declared as "0." This proposal is consistent with the rules set forward in the supplementary nutrition labeling proposal for declaration of fat in the nutrition label.

FDA is proposing in § 101.62(b)(6)(iii) that the type size of all components of the "____ percent fat free" claim be uniform. FDA is concerned that claims that would give the numerical percentage in smaller type size than the words "fat free" would lead consumers to focus only on the "fat free" portion of the claim, misleading them into believing that the food was totally free of fat.

Finally, § 101.62(b)(6)(iv) proposes that a "100 percent fat free" claim must meet all of the criteria in § 101.62(b)(1) for "fat free" claims. This would require that, in addition to containing less than 0.5 g of fat per serving, the food will have to contain no added ingredient that is a fat or oil, and if the food is inherently free of fat, the label will have to so indicate by use of the term "a 100 percent fat free food."

The agency requests comments on these proposed provisions for the use of "____ percent fat free" claims. Specific comments on whether these provisions are sufficient to prevent such claims from being misleading, or whether such claims should be prohibited entirely, are requested.

C. Fatty Acid Claims

In response to the 1989 ANPRM, FDA received very few comments that addressed nutrient content claims regarding fatty acids. However, not only do the 1990 amendments require in section 403(r)(2)(A)(i) of the act that claims characterizing the level of nutrients required in nutrition labeling be made in accordance with definitions adopted by FDA, they add section 403(r)(2)(A)(iv) to the act. This section states that a claim "may not be made with respect to the level of saturated fat in the food if the food contains cholesterol unless the label or labeling of the food discloses the level of cholesterol in the food in immediate proximity to such claims and with appropriate prominence which shall be no less than one-half the size of the claim with respect to the level of saturated fat."

In accordance with these provisions, the agency is proposing in § 101.62(c) to provide for the proper use of the terms "low in saturated fat" and "reduced in saturated fat" and of comparative statements about the content of saturates. As required in the 1990 amendments, proposed § 101.62(c) requires that labels of foods containing 2 mg or more of cholesterol per serving that bear any of the claims being proposed for saturated fat, disclose the level of cholesterol in the food in immediate proximity to such claim and with appropriate prominence which must be no less than one-half of the size of the claim. FDA is proposing to exempt foods containing less than 2 mg of cholesterol per serving from this requirement because the agency is proposing in this rulemaking that such foods be considered "free" of cholesterol and the amount be declared as zero in nutrition labeling.

The agency is also proposing in § 101.62(c) to require that the amount of total fat be disclosed in immediate proximity to claims about saturated fat. The agency believes that disclosure of

total fat is needed because recent FDA research suggests that consumers often do not differentiate between total fat and saturated fat content (Ref. 30). This finding leads FDA to tentatively conclude that "low" or "reduced" saturated fat claims would often be interpreted as "low" or "reduced" total fat claims. Such an interpretation would be incorrect because not all foods that are low in saturates are low in total fat (e.g., some vegetable oils and nuts are low in saturates yet contain about 14 g of total fat per serving). Accordingly, the agency believes a saturated fat claim will be misleading under section 201(n) and 403(a) of the act if the total fat content is not disclosed in immediate proximity to such claim.

1. "Low in Saturated Fat"

a. *Definition.* The agency is defining the term "low in saturated fat" (or "low saturated fat," "contains a small amount of saturated fat," "low source of saturated fat," or "little saturated fat") in proposed § 101.62(c)(1)(i) to describe foods that contain 1 g or less of saturated fatty acids per serving and not more than 15 percent of calories from saturated fatty acids.

The agency derived the first criterion (i.e., 1 g or less of saturated fatty acids per serving) of its proposed definition for "low in saturated fat" following the general approach to defining "low" claims that is discussed in the companion document on nutrient content claims published elsewhere in this issue of the **Federal Register** and summarized under the above discussion for "low fat" claims. As discussed above, this general approach suggests that the starting point for the definition of "low" for a nutrient is 2 percent of its DRV. If a nutrient is not ubiquitous in the food supply, the percent of the DRV used as the cutoff is increased to adjust for its uneven distribution.

With respect to saturated fatty acids, current dietary guidelines (Refs. 6, 8, and 9) recommend that a person consume less than 10 percent of calories from saturated fats, which for a diet of 2,350 calories per day would allow for consumption of about 25 g of saturated fat per day. This value has been proposed as the DRV for saturates (55 FR 29476). Two percent of this proposed DRV is 0.5 g.

However, the agency is not proposing 0.5 g as the cutoff of a "low in saturated fat" claim because saturated fat is not ubiquitous in the food supply. Very little saturated fat is found, for example, in most fruit, vegetables, and grains. Because of the uneven distribution of saturated fat, the agency tentatively concludes that an appropriate upper limit for a "low saturated fat" claim should be set at two times 2 percent of the DRV, or 1 g per serving. Doubling the 2 percent level is consistent with the agency's treatment of fat, and the distribution of saturated fat in the diet roughly parallels the distribution of total fat. Moreover, this amount appears to be a reasonable definition for "low saturated fat" because if a person consumed an average level of 1 g in 16 to 20 servings of food per day, he or she would consume 16 to 20 g of saturated fat daily, comfortably within the DRV of 25 g of saturated fat.

Therefore, the agency is proposing in § 101.62(c)(1)(i) that the first criterion for the definition of "low in saturated fat" be 1 g or less of saturated fat per serving. According to FDA's Regulatory Food Composition Data Base (Ref. 25), this criterion would allow a "low saturated fat" claim on foods such as most fruit, vegetables, and grains; skim milk and other dairy foods made from skim milk; evaporated milk; a few nondairy cream substitutes and dessert toppings; egg substitutes; mayonnaise-style salad dressing; and many soups, breads, and low calorie salad dressings. Of the fats and oils food group, only a few oils, such as canola and safflower, and a few margarine spreads containing less than 40 percent fat meet the criterion of 1 g or less saturated fat. While FDA's Regulatory Food Composition Data Base is not representative of the entire food supply and does not contain foods that have recently been introduced in the marketplace, it gives an indication of the types of food categories that would meet the subject criterion.

b. *Need for second criterion.* A general discussion of the need for a second criterion in establishing definitions for nutrient content claims can be found in the companion document on nutrient content claims which is published elsewhere in this issue of the **Federal Register.** The agency has stated that it believes a second criterion is needed to control "low" claims on nutrient-dense foods with small serving sizes where such food items can be consumed frequently, resulting in a substantial intake of the nutrient. The agency then proposed using g of the nutrient per 100 g of food as the preferred second criterion.

In considering the appropriateness of using "per 100 g" as the second criterion for "low in saturated fat," two things become apparent. First, fats and oils that are commonly consumed generally contain only fat, and, second, 100 g of these foods would rarely, if ever, be consumed in a day. Furthermore, a review of FDA's Regulatory Food Composition Data Base (Ref. 25) revealed that of those fats and oils identified above as containing 1 g or less of saturated fat per serving, none would be able to make "low saturated fat" claims if a second criterion based on 100 g is included in that definition. Because all fats and oils contain more than 1 percent saturated fatty acids, they would exceed 1 g of saturated fat per 100 g.

The agency believes that it is important that consumers be able to easily identify fats and oils that contain especially low levels of saturated fats. While the information needed to make this assessment will be located on the nutrition label once the revised mandatory nutrition labeling regulations are finalized, comments have clearly shown that many consumers use nutrient content claims to make purchase decisions rather than relying on the more complete nutrient content information in the nutrition label. Accordingly, the agency tentatively concludes that a "low saturated fat" claim would be helpful to consumers in identifying such foods, and that the identification, and subsequent purchase, of such foods will help individuals to meet dietary recommendations. The agency also believes that it will assist in reaching population goals such as the "Healthy People 2000" national objective of reducing average saturated fat intake to less than 10 percent of calories (Ref. 24). Additionally, such claims will provide an incentive to the food industry to develop fats and oils with lower levels of saturated fatty acids.

Accordingly, FDA is not proposing to use a second criterion based on weight for "low saturated fat claims". However, the agency continues to be concerned about saturated fat content claims made on small servings of food that may be consumed frequently and thereby result in a substantial total daily intake of saturated fat. In addressing this issue, FDA looked at similar definitions used by other nations. Canada defines "low saturates" as foods containing no more than 2 g of saturated fatty acids per serving and not more than 15 percent calories from saturated fatty acids (Ref. 31). In the United Kingdom (UK), a food is considered to be low in saturated fat if it contains 3 g or less saturates per serving and per 100 g of food (Ref. 32). In setting their per serving criterion at 2 and 3 g, respectively, both countries are far less restrictive on that primary criterion than the subject proposal; however they both seem to share FDA's concern over the need for a second criterion. The British (UK) compensate

by setting a second criterion at 3 g per 100 g of food, a criterion what would eliminate many foods with small serving sizes.

FDA has studied and finds merit in Canada's approach of no more than 15 percent of calories coming from saturated fats. While dietary recommendations are for less than 10 percent of calories in the diet being provided by saturated fat, the fact that saturated fat is not ubiquitous in the food supply would allow higher amounts in those foods that contain saturated fats to balance off those that are lower, resulting in a total daily diet that meets dietary recommendations.

The use of a second criterion of no more than 15 percent of calories from saturated fat would continue to allow for "low saturated fat" claims on most fruit, vegetables, and grains; skim milk and other dairy foods made from skim milk; a nondairy liquid cream substitute; egg substitutes; mayonnaise-style salad dressing; many soups, breads, and low calorie salad dressings; and canola and safflower oils. Those foods that would meet the first criterion but not a criterion of no more than 15 percent of calories from saturated fats include evaporated milk, nondairy dessert toppings, and the margarine spreads. The agency tentatively concludes that it is appropriate to prohibit these foods from bearing a "low saturated fat" claim because they all could be consumed frequently, resulting in a substantial daily intake of saturated fat.

Accordingly, FDA is proposing in § 101.62(c)(1)(i) that "low saturated fat" claims may be used to describe the level of saturated fat provided the food contains 15 percent or less of calories from saturated fat as well as 1 g or less of saturated fat per serving. Comments are specifically requested on the suitability of, and need for, the proposed second criterion for "low saturated fat" claims.

c. *Foods inherently "low in saturated fat."* As previously discussed for "low fat" claims, the agency believes that the use of the claim "low in saturated fat" on the labels of foods that are inherently low in saturated fat can be misleading. Accordingly, FDA is proposing in § 101.62(c)(1)(ii) to require that "low in saturated fat" claims on foods that inherently meet the criteria specified in § 101.62(c)(1)(i) refer to all foods of that type and not merely to the particular brand to which the labeling is attached. This is consistent with the general policy on "free" and "low" nutrient content claims proposed in § 101.13(e)(2), which is published elsewhere in this issue of the Federal Register.

For example, raspberries would meet the definition for the term "low in saturated fat." Therefore, if the agency adopts proposed § 101.62(c)(1)(ii), a package of raspberries bearing a saturated fat claim would be labeled "raspberries, a low saturated fat food."

d. *"Low in saturated fat" meal-type products.* FDA is proposing in § 101.62(c)(2)(i) that a "low in saturated fat" claim may be made for a meal-type product that contains 1 g or less of saturated fat per 100 g of product. The proposed policy of basing nutrient content claims on the amount of the nutrient per 100 g rather than on the amount per serving and per 100 g as is done for individual foods is explained above for "low fat" meal-type products.

In its submission (Ref. 22), GMA suggested that for meal-type products "low saturated fat" be defined as 1.2 g or less of saturated fat per 100 g. FDA believes that it would be beneficial and less confusing if it used the same quantitative amount for "low saturated fat" claims for meal-type products that it is proposing on a per serving basis for "low saturated fat" claims on individual foods, 1 g. The proposed value of 1 g of saturated fat per 100 g would permit a "low saturated fat" claim on a 10-ounce meal when the declaration of saturated fat on the nutrition label is 3 g or less. GMA's suggestion would allow it on the same meal when the declaration is 3.5 g or less. FDA does not believe the difference is significant enough to warrant the confusion that would be caused by using different quantitative amounts.

As with other foods, if a meal-type product inherently meets the "low saturated fat" definition, its label will have to reveal that fact if a claim is made. This requirement is set out in proposed § 101.62(c)(2)(ii).

2. "Reduced Saturated Fat"

In proposed § 101.62(c)(3)(i), the agency is defining the term "reduced in saturated fat" ("reduced saturated fat," or "saturated fat reduced") to describe a food that has been specifically formulated or processed to reduce its content of saturated fat by 50 percent or more, with a minimum reduction of more than 1 g per serving from the reference food that it resembles and for which it substitutes.

The agency selected the level of 50 percent for the minimum reduction in saturated fat to qualify for the "reduced in saturated fat" descriptor in accordance with the general provisions for "reduced" nutrient content claims described above for "reduced fat" foods. These general provisions consider the level of reduction that would result in substantial reductions in the nutrient content of foods, the need for consistency of terms, and the technological feasibility of reducing levels of nutrients in foods. The provisions also consider the need for dietary changes relative to current intakes of nutrients.

Comments from both consumers and health professionals to the 1989 ANPRM and at the public hearings urged consistency in the definitions of terms to assist consumers in understanding the meaning of terms. They suggested that unless there were compelling reasons to the contrary, the agency should revise the current definitions for "reduced" calories, fat, and sodium that were 33 percent, 50 percent, and 75 percent, respectively, because it was not reasonable to expect consumers to remember the definition for each. Such variability, they argued, defeated the purpose of the terms.

In response to these comments and because of the many similarities between saturated fat and total fat, FDA believes that it is appropriate to use the same percent reduction to define "reduced" for both food components. Being absent from most fruit, vegetables, and grain products, neither food component is ubiquitous in the food supply. Therefore, similar levels of reduction could be expected to have a significant impact on dietary intakes of both.

In support of this position, FDA compared the need for dietary changes in saturated fat relative to current intakes with that for total fat discussed above under "reduced fat" claims. Current guidelines recommend reducing saturated fat from the current level in the average U.S. adult diet of 13 percent of calories (Ref. 1) to less than 10 percent of calories (Refs. 6, 8, and 9). This will require a reduction in saturated fat intake of 29 percent (Ref. 27). The need for dietary changes in total fat relative to current intakes is 23 percent, a comparable value. This information, and the agency's desire to provide for consistent definitions for similar terms so that consumer education efforts can be more easily implemented, have led FDA to propose that the first criterion for "reduced saturated fat" claims be a reduction of saturated fat of 50 percent or more.

FDA is also proposing in § 101.62(c)(3)(i) a second criterion that the amount of saturated fat in a food bearing a "reduced saturated fat" claim be reduced as a minimum by more than 1 g per serving from the reference food to which it is being compared. This criterion is consistent with the agency's

position discussed above for "reduced fat" claims and is intended to preclude manufacturers from making inconsequential changes in their products that, because of the initial low level of the nutrient, result in considerable reductions in terms of percent but not in terms of absolute amounts.

As stated above, the agency has tentatively concluded that if a food is to make a consequential as well as measurable reduction in a nutrient, the absolute reduction should not be less than that amount that is defined as "low" on a per serving basis. For saturated fat, that amount would be "more than 1 g."

As proposed in § 101.13(j)(1) of the companion document on nutrient content claims, the reference foods against which "reduced" claims may be measured are either an industry-wide norm or the manufacturer's regular product. These reference points are defined and discussed above in the section on "reduced fat" claims.

The agency is proposing in § 101.62(c)(3)(ii) that a food that bears the claim "reduced in saturated fat" be labeled as required in proposed § 101.13(j)(2), which is included in the companion document on nutrient content claims. Thus, proposed § 101.62(c)(3)(ii) requires that in immediate proximity to the most prominent use of the claim, information be presented on the extent (percent or fraction) that the saturated fat has been reduced, the identity of the reference food to which it is compared, and the actual quantity of saturated fat in a serving of the food compared to the amount in the reference food. For example, a nondairy creamer that had been reformulated to reduce its saturated fat content from the industry-wide norm could make a "reduced saturated fat" claim when accompanied by the following information: "Contains 50 percent less saturated fat than the national average for nondairy creamers. Saturated fat reduced from 3 grams per serving to 1.5 grams per serving."

3. Comparative Claims

Consistent with the discussion of comparative claims describing the fat content of foods, FDA is proposing in § 101.62(c)(4) to allow the use of comparative claims using the term "less" for foods that have been formulated, reformulated, altered, or processed in a way that has resulted in at least a minimum reduction in their saturated fat content. Proposed § 101.62(c)(4)(i) requires a reduction of 25 percent or more in saturated fat and a minimum reduction of more than 1 g of saturated fat per serving from a reference food. The agency believes that a reduction of 25 percent or more is necessary to ensure that consumers are not misled by claims for reductions that are inconsequential, i.e., that the products will serve a useful role in the diet of those individuals who are attempting to limit their consumption of saturated fat.

Additionally, the requirement for an absolute reduction of more than 1 g is necessary to preclude manufacturers from making comparative claims for products that are relatively low in saturated fat and therefore in which even a high percentage reduction in saturated fat content would be inconsequential. For example, without the inclusion of an additional criterion, a food containing only 2 g of saturated fat per serving could be reformulated to contain 1.5 g of saturated fat per serving and thereby qualify to use a comparative claim. In fact, the reduction of 0.5 g of saturated fat cannot be considered either substantial or of nutritional significance.

As discussed under comparative claims for fat, FDA is proposing in § 101.13(j)(1) in the companion document on nutrient content claims that for comparative claims, the reference food may be an industry-wide norm, the manufacturer's regular product, or, when the comparison is to a class of similar foods, to a current, valid data base such as USDA's Handbook No. 8, "Composition of Foods, Raw, Processed, Prepared."

Additionally, the labeling requirements proposed in § 101.62(c)(4)(ii) are identical to those for "reduced saturated fat" claims in proposed § 101.62(c)(3)(ii). The information that must be presented in immediate proximity to the most prominent use of the comparative claim is the percent or fraction that the saturated fat is reduced, the identity of the reference food to which the comparison is made, and the quantitative information that compares the actual amount of saturated fat in a serving of the food to the amount in the reference food.

4. Need for Additional Definitions

The agency is requesting comments on whether there are any other definitions that are necessary to effectively inform consumers about fat and fatty acid content. The agency is not proposing definitions for terms that describe the content of monounsaturated or of polyunsaturated fatty acids. Although the supporting text in some consensus reports (Refs. 6 and 9) noted the likelihood of reducing the risk for CHD (Ref. 9) and atherosclerotic cardiovascular disease (Ref. 6) when specific unsaturated fatty acids are substituted for saturated fatty acids in the diet, the conclusions of these reports did not include quantitative recommendations with respect to intakes of these fatty acids. Therefore, the agency has tentatively concluded that, except for use of the comparative term "more," which is discussed in the companion document on nutrient content claims, the scientific evidence is not sufficiently clear to establish the need for nutrient content claims for unsaturated fatty acids. The agency invites comments on this view.

The agency also is not proposing to define the term "saturated fat free." The agency has proposed in § 101.62(c)(1)(i) to establish a per serving criterion for "low in saturated fat" claims at 1 g or less. This amount is approximately ⅓ the level of fat that it has proposed would qualify for the "low fat" descriptor (3 g or less per serving) and corresponds with dietary guidance that saturated fat should amount to no more than ⅓ of the total fat intake in the diet. The agency believes that the amount of saturated fat that would justify a "saturated fat free" claim should similarly be ⅓ of the maximum fat content permitted to make a "fat free" claim. This standard would result in a criterion of 0.17 g or less of saturated fat per serving. Analytical methodologies for assessing saturated fat content are not precise at such low levels, however. Also, from a food processing point of view, control at such a low level may be difficult. Therefore, the agency has concluded that a "saturated fat free" claim is not feasible.

5. Other Comments

Several comments to the tentative final rule argued that the declaration of fatty acid content ought to be mandatory within nutrition labeling and recommended breaking out additional subcomponents, such as omega-3, omega-6, and trans fatty acids.

At the time the tentative final rule was issued, the 1990 amendments had not been passed. As a result, including saturated fatty acids as a required element of nutrition labeling was only a proposal, and the agency could not assume that this proposal would be adopted. Hence, FDA included discussions on the type and form of fatty acid labeling in the tentative final rule. With the passage of the 1990 amendments, the inclusion of saturated fat within nutrition labeling has become more of a certainty.

The issue of exactly what should be included in nutrition labeling, including what type of breakdown of fatty acid content should be included, is being considered as a part of the agency's supplementary nutrition labeling proposal. Therefore, there is no need to consider that issue as part of this rulemaking.

D. Cholesterol Claims and Responses to Comments to the Tentative Final Rule

1. Thresholds and Other General Requirements for Cholesterol Claims

a. *Saturated fat thresholds.* Several comments to the tentative final rule on cholesterol nutrient content claims (55 FR 29456) objected to the saturated fat thresholds on cholesterol claims. Many of these comments asserted that FDA did not have the legal authority to prohibit truthful claims. They stressed the need for consumer education rather than prohibition of claims. One comment argued that scientific evidence does not show that following dietary guidelines to reduce fat and saturated fat intake will decrease the risk of CHD.

While the agency concluded that it had the authority under sections 403(a)(1), 201(n), and 701(a) of the act to propose threshold levels of fat and saturated fat in the tentative final rule (55 FR 29456), its authority was clarified by passage of the 1990 amendments, particularly section 403(r)(2)(A)(vi) of the act. This section states that a nutrient content claim "may not be made if the Secretary by regulation prohibits the claim because the claim is misleading in light of the level of another nutrient in the food."

One of the main purposes of this rulemaking is, by defining cholesterol content claims, to provide consumers with information that they can use to reduce their risk of CHD. There is convincing evidence that dietary intake of saturated fatty acids is also a significant factor in the etiology of this disease. The Surgeon General's Report, for example, states that "excessive saturated fat consumption is the major dietary contributor to total blood cholesterol levels" (Ref. 5, p. 11), and the NAS's "Diet and Health" report found a strong relationship between blood cholesterol levels and the prevalence and incidence of atherosclerotic CHD (Ref. 6). Accordingly, the agency believes it would be misleading for a food that contains significant amounts of saturated fatty acids to make claims regarding cholesterol content and, thereby, to encourage consumers to buy the product for the purpose of reducing their risk of heart disease.

The agency agrees that consumer education programs are necessary to explain the relationship of cholesterol and saturated fat to the risk of cardiovascular disease. However, FDA is not persuaded that such programs can effectively reach and be understood by all consumers. A recent FDA consumer survey found that 40 percent of respondents thought that a "cholesterol free" food would also be low in saturated fat, and another 20 percent were not sure what the claim implies about saturated fat content (Ref. 33). The survey found that consumers are interested in cholesterol content claims because they believe that eating foods with no or low cholesterol will have a significant effect on their blood cholesterol levels and on their chances of developing heart disease (Ref. 33). These findings lead FDA to conclude that a significant number of consumers are likely to believe that a food that bears a cholesterol content claim will help to lower blood cholesterol levels and to reduce the risk of heart disease. In point of fact, foods containing little or no cholesterol can contain saturated fats at levels that can contribute to high blood cholesterol which, in turn, can contribute to atherosclerotic CHD (Ref. 6). Accordingly, FDA continues to believe that to ensure that cholesterol content claims do not mislead consumers, it is necessary to permit their use only when the foods also contain levels of saturated fats that are below a specified threshold level.

The agency, therefore, is proposing in § 101.62(d) to prohibit the use of cholesterol content claims, including, in a change from the tentative final rule, "reduced cholesterol" and comparative claims, on foods that contain more than 2 g of saturated fatty acids per serving.

b. *Appropriate threshold level for saturated fat.* Many comments suggested changing the threshold levels for saturated fatty acids. The agency had proposed levels of 2 g or less per serving and 6 percent or less saturated fat on a dry weight basis. Most of the comments were opposed to the percent dry weight criterion. They argued that a dry weight limit would discourage the development of new food products with lower fat and cholesterol contents, particularly those in which water is substituted, in part, for fat. Comments stated that the development of new food technologies to produce more healthful foods would be hampered, and that the dry weight criterion was unnecessary and would unfairly penalize foods that have a high moisture content. One comment also objected to the 2 g criterion and suggested lowering the threshold level to 1 g, related to suggested changes in the definition of "saturated fatty acids."

The agency is persuaded that the dry weight criterion is not necessary and is possibly counterproductive to the "Healthy People 2000" objective of increasing the availability of processed food products that are reduced in fat and saturated fat content (Ref. 24). Accordingly, FDA is deleting the dry weight criterion.

In regard to the definition for "saturated fatty acids," the agency noted in the tentative final rule on cholesterol nutrient content claims (55 FR 29469) that this definition was the subject of another rulemaking, namely the proposed rule entitled "Food Labeling; Mandatory Status of Nutrition Labeling and Nutrient Content Revision." The discussion of this definition has been carried forward in the agency's supplementary mandatory nutrition labeling proposal. FDA recognizes the relationship between the definition, that is, the particular fatty acids that are included in the definition, and the numerical value associated with this threshold level (as well as the values defining "low" and "reduced" saturated fat) and will make adjustments in the proposed threshold level as necessary if the definition is modified in the associated rulemaking on nutrition labeling. However, if the definition of "saturated fatty acids" is not modified, the agency does not find compelling reasons, given in the comments, to revise the per serving value of 2 g. Accordingly, FDA is proposing in § 101.62(d)(1)(i)(B) and (d)(1)(ii)(B), (d)(2)(i)(B) and (d)(2)(ii)(B), and (d)(4)(i)(B) and (d)(4)(ii)(B) that the terms "cholesterol free," "low cholesterol," and "reduced cholesterol," respectively, be allowed only when the food product contains 2 g or less of saturated fatty acids per serving. A similar requirement is proposed for comparative cholesterol claims in § 101.62(d)(5)(i)(B) and (d)(5)(ii)(B).

As a result of this 2 g saturated fat threshold above which cholesterol claims may not be used, FDA tentatively concludes that it is not necessary to propose a requirement, based on section 403(r)(2)(A)(iii)(II) of the act, that the saturated fat content be disclosed adjacent to a cholesterol claim whenever the amount of saturated fat exceeds a set value. As discussed in the companion document on descriptor claims published elsewhere in this issue of the **Federal Register**, FDA is proposing in § 101.13(h) that the disclosure level for saturated fat be 4 g per serving or per 100 g. This value is 15

percent of the proposed DRV for saturated fat and is proposed as the level of saturated fat "that increases to persons in the general population the risk of disease or a health related condition which is diet related" as required by section 403(r)(2)(A)(iii) of the act. Because the agency is proposing that it would be misleading to make a cholesterol claim on a food exceeding 2 g of saturated fat, disclosure of levels of 4 g and above have no application to cholesterol claims.

c. *Fat thresholds.* Many comments to the tentative final rule (55 FR 29456) were opposed to the use of a total fat threshold that would prohibit cholesterol claims on foods that contain more than 5 g fat per serving and more than 20 percent fat on a dry weight basis. Some of these comments argued that current scientific knowledge does not support an association between the intake of total fat and high blood cholesterol as it does with saturated fatty acid intake, and therefore that a limit on total fat does not pass scientific scrutiny. Comments also asserted that such a threshold would condone the "good food/bad food" concept by requiring individual foods (and even ingredients of foods), rather than the total diet, to meet dietary guidelines of less than 30 percent of calories from fat.

A few comments pointed out that FDA surveys show that many consumers believe that cholesterol is found in all fats and oils, and that this finding demonstrates that there is a need for consumer education (which could include declarative statements adjacent to claims informing consumers of the total fat content of the product) rather than removal of truthful claims. Comments also stated that a total fat threshold would be a disincentive to the food industry to formulate low cholesterol and low fat foods, which would hinder the achievement of the "Healthy People 2000" objectives (Ref. 24). Comments also pointed out that such a threshold would interfere with harmonization between the U.S. and Canada, because Canada only restricts the saturated fatty acid content of foods making cholesterol claims.

FDA does not agree that a threshold for disallowing a descriptor supports a "good food/bad food" concept. The agency believes that such a threshold merely restricts the use of nutrient content claims to those foods on which they will not be misleading. However, FDA is persuaded by the comments that a cholesterol claim is not inherently misleading on a food that is high in total fat but contains 2 g or less of saturated fatty acids per serving.

The agency notes that Congress in the 1990 amendments appears to have considered that, in appropriate circumstances, cholesterol claims could be made on foods that contain significant levels of fat (see 21 U.S.C. 343(r)(2)(A)(iii)). For example, House Report 101–538 (Ref. 34, p. 20) states that a "no cholesterol" claim may be allowed on margarine, a food that is largely fat, under certain conditions. Accordingly, the agency is deleting the total fat thresholds.

d. *Conditions for use of cholesterol claims on foods exceeding disclosure levels of fat.* A cholesterol claim represents and suggests that the product provides a health benefit, and the level of fat in the food has a material bearing on this claim. This position is supported by section 403(r)(2)(A)(iii) of the act, which states that if a food contains fat or saturated fat in an amount that increases the risk for persons in the general population of developing a diet-related disease or health condition, it may not make a claim with respect to cholesterol unless it meets certain requirements and discloses the amount of total fat or saturated fat in immediate proximity to such claims.

Section 403(r)(2)(B)(ii) of the act provides similar language for nutrient content claims with the requirement that any nutrient in a food at a level that increases risk of diet related disease or health condition shall prominently disclose that nutrient on the label or in labeling in immediate proximity to the claim. FDA is referring to this level as a "disclosure level." The act goes even further with respect to health claims. In section 403(r)(3)(A)(ii), the act prohibits, except in special circumstances, health claims for a food if any nutrient is present in the food in an amount that increases the risk of diet-related disease or health condition. FDA will refer to this level as a "disqualifying level." The statutory language defining a disclosure level for a nutrient in conjunction with a nutrient content claim is the same as that for a disqualifying level for the nutrient for a health claim. Consequently, FDA is proposing the same levels for the individual nutrients for both types of claims.

The disclosure level for fat is proposed in § 101.13(h) of the companion document on nutrient content claims as an amount that is more than 11.5 g per serving or per 100 g of food. The identical amount is proposed in § 101.14(a)(5) of the proposed rule on health claims published elsewhere in this issue of the **Federal Register** as the disqualifying level for fat for health claims. In the proposed rule on health claims, the agency discusses how it arrived at the proposed disclosure and disqualifying levels.

Briefly, in setting such levels, FDA considered that there are no generally recognized levels at which nutrients such as fat, saturated fat, cholesterol, or sodium in an individual food will pose an increased risk of disease. Therefore, if FDA were to attempt to set these levels on an individual food basis, it would not be possible to do so. However, sections 403(r)(2)(B)(ii) and 403(r)(3)(A)(ii) of the act require that the agency take into account the significance of the food in the total daily diet. The intake of nutrients such as fat, saturated fat, and cholesterol in the total day's diet in excess of dietary recommendations increases the risk of diet-related disease. Therefore, because the agency's proposed DRV's for total fat, saturated fat, cholesterol, and sodium are based on recommended dietary intake levels, the agency tentatively decided to tie the disclosure and disqualifying levels to the DRV's.

To determine the appropriate disclosure/disqualifier levels, FDA used an approach based on the number of servings of food in a day and available information on food composition. As described in the health claims proposal, the agency has tentatively found that an appropriate disclosure/disqualifying level for individual foods is between 10 and 20 percent of the DRV. The agency made this tentative finding by looking at the food supply. It noted that the nutrients fat, saturated fat, cholesterol, and sodium are present in roughly one-half of the general USDA food categories. Therefore, if approximately 20 foods/beverages are consumed in a day and half of the foods consumed contain the nutrient at a level of 10 percent of the DRV (on average), then the total daily intake of the nutrient would be 100 percent of the DRV. This level of intake would not constitute a risk for chronic disease. On the other hand, if the same number of foods are consumed and half the foods contain on average 20 percent of the DRV, then the total daily intake of the nutrient would be 200 percent of the DRV, a level of intake that would increase the risk for diet-related disease. The agency then used food composition data to evaluate the effect of establishing various disclosure/disqualifying levels between 10 and 20 percent and tentatively concluded that a level of 15 percent of the DRV was most appropriate. If one-half of the foods consumed during the day contains on average this amount, the total daily intake of the nutrient

would exceed the DRV but without the risks inherent at higher levels. Yet, if this criterion is used, a significant number of foods would not be disqualified. Thus, FDA is proposing to establish disclosure/disqualifying levels for total fat, saturated fat, cholesterol, and sodium, and that these levels be 15 percent of the DRV per serving and per 100-g of food. These levels are 11.5 g for total fat, 4.0 g for saturated fat, 45 mg for cholesterol, and 360 mg for sodium. FDA is proposing that the disclosure/disqualifying levels apply on a 100–g basis as well as on a serving size basis to prevent nutrient-dense foods (i.e., those foods that contain relatively high concentrations on a caloric basis of one or more of the subject nutrients) that are consumed in small servings from being promoted for increased use in a diet through the use of health claims or nutrient content claims.

Accordingly, to implement section 403(r)(2)(A)(iii) of the act, FDA is proposing in § 101.62(d)(1)(ii)(C), (d)(2)(ii)(C), (d)(4)(ii)(C), and (d)(5)(ii)(C) that a "cholesterol free," "low cholesterol," "reduced cholesterol," or a comparative claim, respectively, may be made on foods containing more than 11.5 g of fat per serving or per 100 g of food only if, in addition to meeting the requisite cholesterol and saturated fat levels, the food label or labeling discloses the level of total fat in a serving of the food as labeled. The agency believes this requirement, if adopted, will prevent consumers from being misled about the health benefits of the product by the cholesterol claim.

In accordance with section 403(r)(2)(A)(iii)(II) of the act, FDA is also proposing in these paragraphs that the disclosure of fat must appear in immediate proximity to such claim and with appropriate prominence, that is in type that is no less than 1/2 the size of the type used for such claim. Because the level of fat has a material bearing on the claim, FDA is proposing that the disclosure of fat come immediately after the claim and before the referral statement required by § 101.13(g) (i.e., "See [*appropriate panel*] for nutrition information"). To limit unnecessary duplication of information, FDA is also proposing that if the claim appears on more than one panel, the requirement of the act will be met if the fat content is disclosed adjacent to the claim on each panel except for the panel that bears nutrition labeling, where it will not be required. Likewise, if the claim appears more than once on a panel, the requirement of the act will be met if the fat content is disclosed adjacent to the claim that is printed in the largest type on that panel. This proposal is similar to that proposed in § 101.13(g) of the companion document on nutrient content claims regarding the referral statement.

In addition to requiring that total fat levels be disclosed in immediate proximity to any cholesterol claims made on labels of foods that have more than 11.5 g of fat, section 403(r)(2)(A)(iii) of the act identifies two other conditions for use of cholesterol claims on such foods. These conditions are: (1) "the Secretary finds by regulation that the level of cholesterol is substantially less than the level usually present in the food or in a food which substitutes for the food and which has a significant market share," or (2) "the Secretary by regulation permits a statement regarding the absence of cholesterol on the basis of a finding that cholesterol is not usually present in the food and that such a statement would assist consumers in maintaining healthy dietary practices and the regulation requires that the statement disclose that cholesterol is not usually present in the food" (21 U.S.C. 343(r)(2)(A)(iii)(I)).

i. *Substantially less.* In regard to the first condition, FDA is proposing in § 101.62(d)(1)(ii)(E) and (d)(2)(ii)(E) to permit "free" and "low" cholesterol claims to be made on foods that contain more than 11.5 g of total fat if the foods meet the required cholesterol levels for the claim as a result of special processing, alteration, formulation, or reformulation that caused them to contain "substantially less" cholesterol than the reference foods.

The agency is proposing in § 101.62(d)(1)(ii)(E) and (d)(2)(ii)(E) to define "substantially less" in a way that is consistent with the requirements of § 101.62(d)(5)(i)(A) for a comparative claim using the term "less." Proposed § 101.62(d)(5)(i)(A) provides that to make a comparative claim, a food must contain at least 25 percent less cholesterol, with a minimum reduction of more than 20 mg of cholesterol per serving, than the reference food. The 25 percent reduction is consistent with the agency's position that a 25 percent or greater reduction in a nutrient for which excess consumption is a public health concern is consequential (that is, substantial) because it will assist persons attempting to limit their consumption of the nutrient to meet dietary recommendations. This position is the basis for comparative claims for sodium (49 FR 15510 at 15521, April 18, 1984) and for cholesterol as proposed in § 101.25(a)(2)(iv) of the tentative final rule. It also corresponds with USDA guidelines that permit comparative fat claims for meat and poultry products when fat is reduced by 25 percent.

FDA is proposing, as the second criterion for "substantially less," a minimum reduction of more than 20 mg of cholesterol per serving to preclude manufacturers from making inconsequential changes in a product, which, because of the initial low level of the nutrient, results in considerable reductions in terms of percent but not in terms of absolute amounts. The level of more than 20 mg cholesterol is that amount which exceeds the level proposed for a "low cholesterol" claim. FDA has tentatively concluded in its companion document on nutrient content claims that if a food is to make a consequential as well as a measurable reduction in a nutrient, the absolute reduction should not be less than that amount which is considered to be "low."

In reference to the requirement in section 403(r)(2)(A)(iii)(I) of the act that the level of cholesterol be less than the level usually present in the food "or in a food which substitutes for the food," the agency is proposing in § 101.62(d)(1)(ii)(E), (d)(2)(ii)(E), (d)(4)(ii)(A), and (d)(5)(ii)(A) for "cholesterol free," "low cholesterol," "reduced cholesterol," and comparative cholesterol claims, respectively, that the substitute food meet the requirements for a substitute food proposed in § 101.13(d) of the companion document on nutrient content claims. Proposed § 101.13(d) states that a substitute food is a food that organoleptically, physically, and functionally resembles the food for which it substitutes, that may be used interchangeably with such food, and that is not nutritionally inferior (as defined in current § 101.3(e)(4)). For example, vegetable oil margarine resembles butter in its performance characteristics (i.e., organoleptic properties, physical attributes, and functional properties), is used interchangeably with butter, and is not nutritionally inferior to butter. Therefore, a "cholesterol free" claim would be allowed for vegetable oil margarine on the basis that it substitutes for butter and contains substantially less cholesterol than butter.

Section 403(r)(2)(A)(iii)(I) of the act also requires that the substitute food discussed in the preceding paragraph have a "significant market share." FDA is proposing to find that a food has a significant market share if it has a market share of 5 percent or more of the sales of that category of foods according to an authoritative marketing data base. Examples of national data bases of food sales include those developed by The A.C. Nielsen Co. and Information

Resources, Inc. The agency is proposing to define "significant market share" as 5 percent or more because, for most categories of foods, products with less than this amount are not likely to remain on the market. Many retailers will not carry products with less than 5 percent of the market, and manufacturers find it uneconomical to continue to produce and market such products (Ref. 35). Therefore, in proposed § 101.62(d)(1)(ii)(E), (d)(2)(ii)(E), (d)(4)(ii)(A), and (d)(5)(ii)(A) for "cholesterol free," "low cholesterol," "reduced cholesterol," and comparative cholesterol claims, respectively, FDA is proposing to parenthetically define "significant market share" as a market share of 5 percent or more.

The agency is also proposing in § 101.62(d)(1)(ii)(E) and (d)(2)(ii)(E) that foods containing more than 11.5 g of fat per serving or per 100 g of food that make "free" and "low" cholesterol claims on the basis of containing "substantially less" amounts than another food be labeled in accordance with proposed § 101.13(j)(2) for all relative claims. Similar requirements exist in § 101.62(d)(4)(i)(C) and (d)(4)(ii)(D) for foods making "reduced cholesterol" claims and in § 101.62(d)(5)(i)(C) and (d)(5)(ii)(D) for foods making comparative cholesterol claims. Thus, if the agency adopts these requirements, the label or labeling would have to bear, in immediate proximity to the claim, a statement of the percent of reduction, identification of the reference food, and quantitative information comparing the product's per serving cholesterol content with that of the reference food (e.g., "Cholesterol free margarine, contains 100 percent less cholesterol than butter (0 mg of cholesterol compared with 30 mg in one serving of butter). Contains 11 grams of fat per serving."). (Note: Even though margarine contains less than 11.5 g per serving, it contains more than 11.5 g per 100 g, and therefore a "cholesterol free" claim on this food must disclose the amount of total fat.)

ii. *Absence claims.* The second condition in section 403(r)(2)(A)(iii) of the act for allowing cholesterol claims on foods that have more than 11.5 g of fat is that absence (i.e., "free") claims may be permitted on the basis of a finding that while cholesterol is not usually present in the food, such a claim would assist consumers in maintaining healthy dietary practices, and the claim discloses that cholesterol is not usually present in the food.

Consistent with the discussion on claims for foods that are inherently free of fat, FDA believes it is helpful to consumers to highlight "cholesterol free" foods useful in maintaining healthy dietary practices whether the food is inherently free of cholesterol or is processed to be that way. Several FDA surveys have shown that consumers want and use descriptor claims to identify foods having positive nutritional attributes (Refs. 19 through 21). These survey results, in conjunction with comments to the 1989 ANPRM, have persuaded FDA that the definitions established in this proposed rule respond to consumers' needs and help to educate consumers on the intrinsic properties of foods. Therefore, FDA has tentatively concluded that it is not necessary to limit "cholesterol free" claims to foods in which cholesterol is usually present or that substitute for foods that usually contain cholesterol.

However, the agency is concerned that unrestricted use of "free" claims on foods that are inherently free of cholesterol can be misleading since the claim could imply that the particular brand of food bearing the claim is different from other foods of the same type. Accordingly, FDA is proposing in § 101.62(d)(1)(ii)(D) to require that if a food is inherently free of cholesterol (i.e., it has not been processed, altered, formulated, or reformulated to remove cholesterol) it may make a cholesterol claim only if the claim refers to all foods of that type and not merely to the particular brand to which the labeling is attached (e.g., "Canola oil, a cholesterol-free food"). Such claims are subject to additional disclosure requirements in § 101.62 and § 101.13 (e.g., "Contains 14 g fat per serving" and "See [*appropriate panel*] for information on fat and other nutrients"). (Note: The agency does not consider margarines to be inherently free of cholesterol since the standard of identity for margarine allows for the use of animal fats.)

This requirement is consistent with the general policy on "free" and "low" nutrient content claims stated in rulemaking for sodium (49 FR 15510 at 15517) and cholesterol descriptor claims (51 FR 42584 at 42589 and 55 FR 29456 at 29465) and set forth in current § 105.66(c)(2) for "low calorie" claims. The agency has taken the position that foods inherently free of, or low in, a nutrient should not be labeled with a claim such as "cholesterol free," or "low cholesterol," immediately preceding the name of the food because such terminology would imply that the food has been altered to remove the nutrient as compared to other foods of the same type. Thus, FDA is proposing in § 101.62(d)(2)(i)(C) and (d)(2)(ii)(D) that foods that inherently contain 20 mg or less of cholesterol may be labeled as "low cholesterol" as long as the label makes clear that all foods of that type, and not merely the brand to which the label attaches, are low in cholesterol (e.g., "lowfat cottage cheese, a low cholesterol food").

For the same reasons, FDA is proposing in § 101.62(d)(1)(i)(C) to reflect the statutory language of section 403(r)(2)(A)(ii)(II) of the act by proposing to require that foods that contain less than the disclosure level of fat and that are inherently free of cholesterol must disclose that cholesterol is not usually present if they make a "cholesterol free" claim (e.g., applesauce, a cholesterol free food"). Foods that contain less than the disclosure level of fat and that have been processed to contain less than 2 mg of the cholesterol that is usually present in the food, or that have substitutes that contain cholesterol, can bear a "cholesterol free" claim under section 403(r)(2)(A)(ii)(I) of the act and proposed § 101.62(d)(1)(i)(A).

e. *Application of saturated fat thresholds to "reduced cholesterol" foods.* Comments were mixed on whether the fat and saturated fat thresholds should apply to "reduced cholesterol" claims. Several comments expressed the belief that reduced claims should adhere to the same thresholds as "free" or "low" cholesterol claims to be consistent and, thereby, to avoid consumer confusion and to provide "a level playing field." One such comment expressed the opinion that any cholesterol claim will convey to consumers the impression that a food is a healthy choice, and, therefore, a "reduced cholesterol" claim would be misleading if it did not have the same thresholds as "free" and "low" claims. Opposing comments supported the proposed position of not applying threshold levels to foods making "reduced" claims, stating that the use of thresholds would prevent some foods from making claims, thereby depriving consumers of useful information and the selection of foods with significant reductions in cholesterol.

The agency is convinced by the comments and the scientific evidence that cholesterol content claims can be misleading to consumers if the product contains amounts of saturated fat that contribute to high blood cholesterol levels. As stated above, a cholesterol claim represents and suggests that the product provides a health benefit, and that benefit is missing if the product contains high levels of saturated fat. Therefore, under section 403(r)(2)(A)(vi) of the act, which prohibits a claim if the claim is misleading in light of the level

of another nutrient, the agency is proposing to apply the saturated fat threshold to "reduced" as well as to free" and "low" cholesterol claims. Accordingly, FDA is modifying proposed § 101.25(a)(iii) in the tentative final rule (redesignated as § 101.62(d)(4) in this document) to require that "reduced cholesterol" claims only be used on labels or in labeling of foods that contain less than 2 g of saturated fat per serving. For these reasons, the agency is also including a similar requirement in proposed § 101.62(d)(5) for comparative claims.

2. "Cholesterol Free"

a. *Definition.* FDA first proposed that a "cholesterol free" food be defined as one containing less than 2 mg of cholesterol per serving in its proposed rule of November 25, 1986 (51 FR 42584). The agency selected a cutoff of less than 2 mg of cholesterol because that level is biologically and nutritionally insignificant. Moreover, analytical precision below that limit is not possible (51 FR 42584 at 42588). This quantitative amount was carried forward in the agency's tentative final rule on cholesterol nutrient content claims (55 FR 29456). In the tentative final rule, the agency rejected comments to the 1986 proposal that suggested that the level used in defining "cholesterol free" should be changed. Differing comments had recommended both lowering the defined amount to absolute zero and raising it to 5 mg per serving. FDA responded that a zero level could not be detected with analytical certainty, and that raising the level up to 5 mg could result in consumption of dietarily significant amounts of cholesterol when only "cholesterol free" foods were consumed.

A few comments on the 1990 tentative final rule reiterated comments received on the 1986 proposed rule on cholesterol nutrient content claims (51 FR 42584) that the level used in defining "cholesterol free" should be modified. Comments again recommended lowering the defined amount to zero and raising it to 5 mg per serving. However, none of these comments presented any information that the agency had not already received in response to the 1986 proposal and considered in drafting the tentative final rule.

In its tentative final rule, FDA advised that it considered that document to contain the final determination of the agency on all substantive issues other than on the threshold levels of fat and saturated fatty acids, and that a comment would have to be very significant to cause the agency to make any changes in the rule other than to the threshold levels. Therefore, not being presented with any new evidence, FDA has not revised the level of cholesterol in the definition for "cholesterol free" in proposed § 101.25(a)(2)(i), redesignated in this document as § 101.62(d)(1).

FDA is not proposing a second criterion based on the amount of cholesterol per 100 g for the definition of "free" because the first proposed criterion for "cholesterol free" requires that the food contain such a trivial level of cholesterol from a public health perspective that even frequent consumption in large amounts of food that bear a claim would not affect in any meaningful way the overall cholesterol level in the diet.

b. *Synonyms.* In accordance with the discussion on synonyms in the companion document on nutrient content claims, the agency is proposing in § 101.62(d)(1) to add the term "zero cholesterol," "trivial source of cholesterol," "negligible source of cholesterol," and "dietary insignificant source of cholesterol" as a synonym for "cholesterol free," "free of cholesterol," and "no cholesterol." As suggested in the IOM report on nutrition labeling (Ref. 4), the use of consistent and targeted nutrient content claims increases consumers' confidence in the validity of the claim. The agency requests comments on whether consumers commonly understand the other synonyms to have the same meaning as "free."

3. "Low Cholesterol"

a. *Definition.* In its proposed rule of November 25, 1986 (51 FR 42584), FDA proposed to allow the term "low cholesterol" on the label or in labeling of foods that contain less than 20 mg of cholesterol per serving. The agency found that foods containing less than 20 mg of cholesterol per serving were generally those that had been identified as useful to persons who want to control or moderate their cholesterol intakes or to maintain their cholesterol intakes at relatively low levels.

Comments submitted to the proposed rule persuaded FDA to modify the proposed definition in its tentative final rule: (1) To change the definition from "less than 20 mg per serving" to "20 mg or less per serving," and (2) to add a second criterion based on density, namely that the food contain 0.2 mg or less of cholesterol per g of food. FDA made the first change to be consistent with the agency's other definitions for "low," for calories (§ 105.66(c)(1)(i)) and for sodium (§ 101.13(a)(3)), that include the integer in the definition.

FDA made the second change to prevent "low cholesterol" label claims from conveying a misleading impression about the cholesterol content of certain foods. Comments pointed out that a single criterion based on serving size could result in widely recognized "high cholesterol" foods with small serving sizes (e.g., butter, lard, and some processed cheese foods) being labeled as "low cholesterol." These comments stressed that despite their small serving sizes, such foods actually may be consumed frequently and in large amounts, resulting in a substantial total daily intake of cholesterol. In addition, the comments were concerned that a "low cholesterol" claim on such foods could encourage increased consumption of the food, significantly adding to an individual's total cholesterol intake.

The comments to the tentative final rule fully supported the first criterion for "low cholesterol" claims (i.e., that the food should contain 20 mg or less cholesterol per serving). However, several comments requested the second criterion based on cholesterol density (i.e., 0.2 mg per g) be eliminated. These comments argued that promulgation of a regulation specifying serving sizes would negate the need for the second criterion.

As explained in the companion document on nutrient content claims, the agency has determined that, for the reasons discussed above, there continues to be a need for a second criterion for "low" claims even when FDA's rulemaking on serving sizes is completed (Ref. 36). The agency is proposing in that document to base the second criterion on the amount of the nutrient per 100 g of food.

Accordingly, FDA is proposing to keep the second criterion for the definition of "low cholesterol." However, the agency is modifying proposed § 101.25(a)(ii), redesignated as § 101.62(d)(2), to specify the second criterion as 20 mg per 100 g of food rather than 0.2 mg per g, an identical amount.

This definition is in accordance with the general approach described in the companion document on nutrient content claims for arriving at a definition for "low." This approach is described above in the discussions of the definitions of "low fat" and "low in saturated fat." Under that approach, the definition of "low" for a nutrient that is ubiquitous in the food supply, such as calories, is 2 percent of the DRV. If the nutrient is not ubiquitous but is found in more than a few food categories, such as fat, FDA has proposed to define "low" as two times the level that is 2 percent of the DRV. If the nutrient is found at measurable levels in the foods in only a few food categories, the agency has

proposed to define "low" as three times 2 percent of the DRV. Cholesterol, which is found only in foods of animal origin, is in the latter group. The DRV for cholesterol is 300 mg, 2 percent of which is 6 mg. Therefore, the definition of "low" is 18 mg (three times 6 mg). Rounded to the nearest 5 mg increment as is required in current and proposed nutrition labeling regulations, the proposed level is 20 mg per 100 g of food.

FDA is also proposing in § 101.62(d)(2) to allow the use of the synonymous terms, "contains a small amount of cholesterol" in accordance with the discussion on synonyms in the proposed rule on nutrient content claims.

b. *Definition of "low cholesterol" meal-type product.* As discussed in the companion document on nutrient content claims and above for "low fat" claims for meal type products, the agency has received many comments requesting that FDA provide for the use of nutrient content claims on these products. In recognition of the increasing role that meal-type products have in the marketplace, the agency believes that it is important to establish nutrient content claims that will help consumers to identify positive nutritional characteristics of such products. Accordingly, FDA is proposing in § 101.62(d)(3) that a "low cholesterol" claim may be made for a meal-type product that contains 20 mg or less of cholesterol per 100 g of the product. This value is the same as that suggested by GMA (Ref. 22) and uses the same quantitative amount of cholesterol used to define "low cholesterol" for individual foods. As noted above, FDA finds merit in setting nutrient content claims for meal type products on the basis of the amount of a nutrient per 100 g rather than on the basis of the amount per serving and per 100 g as is done for most "low" claims for individual foods. FDA anticipates that people will not consume more than one or two meal-type products per day, rather than the average of 16 to 20 servings of individual foods (Refs. 15 through 17). Therefore, FDA tentatively concludes that it is not reasonable to expect meal-type products to meet the same per serving criteria as individual foods.

For the same reason, FDA is proposing that the saturated fat threshold in § 101.62(d)(2)(i)(B) and (d)(2)(ii)(B) be modified from 2 g or less per serving to 2 g or less per 100 g. This proposed level would allow a 10 ounce meal that meets the requisite cholesterol levels to make a "low cholesterol" claim if it contained less than 5.5 g of saturated fat, a value that is approximately ⅓ of the DRV for saturated fat. FDA is proposing to make a similar modification in the fat level in § 101.62(d)(2)(i) and (d)(2)(ii). Thus, under proposed § 101.62(d)(3), the determination as to whether § 101.62(d)(2)(i) or (d)(2)(ii) applies will be made on the basis of whether the product contains 11.5 g or less of fat per 100 g of food.

4. "Reduced Cholesterol"

In its proposal of November 25, 1986 (51 FR 42584), FDA proposed to allow a "reduced cholesterol" claim on a food that had been specially formulated or processed to reduce its cholesterol content by 75 percent. The 75 percent criterion reflected FDA's concern about the many foods that contain relatively large amounts of cholesterol, and the possibility that products with relatively high levels of cholesterol could easily claim to have reduced cholesterol content if the agency permitted a lesser reduction.

Comments on the proposed rule requested that the percent reduction be lowered to 30 or 50 percent because the 75 percent requirement was unrealistic and technologically infeasible. FDA was not persuaded that cholesterol levels could not be reduced by 75 percent in many foods, and, in accordance with the agency's intent that the "reduced cholesterol" claim be reserved for those products that accomplished a very substantial reduction in the level of cholesterol, it did not change the requirement in the tentative final rule (55 FR 29456).

Comments to the tentative final rule requested that the agency reevaluate its position on the definition of "reduced cholesterol," suggesting that the definition be lowered from 75 percent to 25 or 33 percent. The comments pointed out that consumption surveys reflect a decrease in consumption of cholesterol over the past two decades, and these comments argued that too stringent a requirement for "reduced cholesterol" would limit the incentive for industry to develop "reduced cholesterol" foods to further this trend.

The agency has reviewed the use of "reduced" claims for cholesterol in light of the general criteria for "reduced" nutrient content claims set out in the companion document on nutrient content claims. These general criteria take into consideration the level of reduction that would result in substantial reductions in the nutrient content of foods, the need for consistency of terms, the technological feasibility of reducing levels of nutrients in foods, and the need for dietary changes relative to current intakes of nutrients.

The basis for defining a substantial reduction of a nutrient in food should include consideration of the distribution of the nutrient within the food supply and the amount of reduction that is necessary to produce a substantial reduction in the amount of the nutrient in the diets of individuals. Dietary cholesterol is not ubiquitous in the food supply. It is found only in foods of animal origin. Accordingly, if dietary intake levels of cholesterol are to be reduced substantially, it is important to make substantial reductions in individual foods that are major sources of cholesterol. FDA has reevaluated what level of reduction constitutes a substantial reduction in cholesterol content for several reasons.

First, FDA's 1988 Food Labeling and Package Survey (FLAPS) did not encounter any foods that made "reduced cholesterol" claims (Ref. 37). A few foods that had removed all of their cholesterol content (i.e., egg substitutes) properly bore "cholesterol free" rather than "reduced cholesterol" claims. These results of the FLAPS survey, in addition to earlier comments about the technological unfeasibility of a 75 percent reduction, are significant.

Moreover, comments indicate that lowering the defined level of reduction for "reduced cholesterol" claims from 75 percent to 50 percent would give industry greater incentive to develop new foods that meet the criterion through special processing or reformulation. In addition, this change would allow for greater consistency in the definitions of "reduced" foods because the agency is proposing that "reduced" claims for sodium, fat, and saturated fat be defined as a 50 percent reduction. The importance of such consistency of terms for consumer education purposes was emphasized at the 1989 public hearings and in comments to the ANPRM.

FDA has also examined the need for dietary change in light of dietary recommendations. In the case of dietary cholesterol, NAS's "Diet and Health" report (Ref. 6) and the NCEP report of the Expert Panel on Population Strategies for Blood Cholesterol Reduction (Ref. 9) recommend consumption of less than 300 mg of cholesterol per day. The agency compared these values to current intake levels reported in a recent food consumption survey and estimates that a reduction in cholesterol intake of 20 percent is needed to lower the cholesterol content of the American diet to amounts recommended in dietary

guidance (Ref. 27). Since substantial reductions in cholesterol can only be made in a few food categories, it is reasonable to triple this value, as was done in calculations above for defining "low cholesterol" foods, to bring the percent change needed to 60 percent, a value that could appropriately be rounded down to 50 percent to maintain consistency with the proposed definitions for "reduced fat," "reduced saturated fat," and "reduced sodium." FDA is persuaded by the comments that a 75 percent reduction, as originally proposed for "reduced cholesterol" claims in 1986 (51 FR 42584) and carried forward in the tentative final rule (55 FR 29456), is not necessary. The factors discussed above, in addition to recent food consumption survey data showing a decrease in cholesterol intake levels, have convinced the agency that the earlier proposed requirement for a 75 percent reduction is not necessary to evoke a sufficient change in the food supply to allow the public to meet current dietary recommendations. Accordingly, the agency is proposing in § 101.62(d)(4)(i)(A) and (d)(4)(ii)(A) that the term "reduced cholesterol" may be used on foods that have been formulated or processed to reduce their cholesterol content by 50 percent.

However, to ensure that a 50 percent reduction amounts to more than an inconsequential reduction in cholesterol content, the agency is also proposing in § 101.62(d)(4)(i)(A) and (d)(4)(ii)(A) to add a second criterion that there be a minimum reduction of more than 20 mg per serving from the reference food. This criterion is consistent with the second criterion for other "reduced" nutrient content claims discussed above and represents an absolute reduction that is no less than the amount which is considered "low."

As proposed in § 101.13(j)(1) of the companion document on nutrient content claims, the reference foods against which "reduced cholesterol" claims are to be measured are either an industry-wide norm or the manufacturer's regular product. These reference points are defined and discussed above in the section on "reduced fat" claims.

The agency is proposing in § 101.62(d)(4)(i)(C) and (d)(4)(ii)(D) that the food that bears a "reduced cholesterol" claim be labeled in compliance with § 101.13(j)(2) as proposed in the companion document on nutrient content claims. This proposed section requires information in immediate proximity to the most prominent use of the claim of the extent (percent or fraction) that the cholesterol is reduced, the identity of the reference food to which it is compared, and the quantitative information comparing the actual amount of cholesterol in a serving of the food to the amount in the reference food.

5. Comparative Claims

Consistent with the earlier discussion of comparative claims describing the fat content of foods, FDA is proposing in § 101.62(d)(5) to allow the use of comparative claims using the term "less" for foods that have been reformulated, altered, or processed in a way that has resulted in a reduction of cholesterol. Proposed § 101.62(d)(5)(i)(A) and (d)(5)(ii)(A) would require a reduction of 25 percent or more in cholesterol and a minimum reduction of more than 20 mg of cholesterol per serving from a reference food. The agency believes that a reduction of 25 percent or more is necessary to ensure that consumers are not misled by claims for reductions that are inconsequential, i.e., that the products will serve a useful role in the diet of those individuals who are attempting to limit their consumption of cholesterol. Additionally, consistent with other relative claims, FDA believes it is important to provide for an absolute reduction that is not less than the amount that is defined as "low" (i.e., more than 20 mg of cholesterol per serving).

As discussed with respect to comparative claims for fat, FDA is proposing in § 101.13(j)(1) in the companion document on nutrient content claims that for comparative claims, the reference food may be an industry-wide norm, the manufacturer's regular product, or, if the comparison is to a class of similar foods, a current, valid data base such as USDA's Handbook No. 8, "Composition of Foods, Raw, Processed, Prepared."

Additionally, the labeling requirements proposed in § 101.62(d)(5)(i)(C) and (d)(5)(ii)(D) are identical to those in proposed § 101.13(j)(2) for all other relative claims. They require, in immediate proximity to the most prominent use of the claim, the percent or fraction that the cholesterol is reduced, the identity of the reference food to which it is compared, and the quantitative information comparing the actual amount of cholesterol in a serving of the food to the amount in the reference food.

IV. Conditions of Use of Defined Terms

A. Foods for Children

In § 101.13(a) of the companion document on nutrient content claims, the agency is proposing to prohibit the use of nutrient content claims, including claims about the fat, fatty acid, or cholesterol content on foods that are specifically intended for infants and toddlers less than 2 years of age. This provision is consistent with the agency's proposed exclusion of the use of claims about cholesterol and fatty acid content in such foods in proposed § 101.25(a)(1)(ii) and (b)(2), respectively, of the tentative final rule on cholesterol nutrient content claims (55 FR 29456).

The agency proposed this provision (55 FR 29456) based on comments to its 1986 proposal on cholesterol nutrient content claims (51 FR 42584). These comments stated that changing the diet of these children toward a more restrictive dietary pattern should await demonstration that such dietary restriction is needed and would support adequate growth and development. The agency agreed with these comments and proposed to exclude the use of nutrient content claims and quantitative cholesterol and fatty acid labeling on foods specifically intended for use by infants and toddlers. The agency tentatively concludes that this exclusion should also apply to fat nutrient content claims because the issue of a suitable dietary pattern for infants and toddlers includes the issue of the total fat content of their diet. There is agreement among the American Academy of Pediatrics, the American Heart Association, the National Institutes of Health's Consensus Conference on Lowering Blood Cholesterol, and the NCEP that fat and cholesterol should not be restricted in the diets of infants (Ref. 38).

Until the agency has information that a more restrictive dietary pattern (as might be encouraged by the use of these nutrient content claims) is appropriate for these children and would support adequate growth and development, the agency is proposing to bar the use of these nutrient content claims on food products that are specifically intended for infants and toddlers.

B. Use of Defined Terms in Conjunction with Statement of Identity

Comments on the 1989 ANPRM addressed the issue of how claims that describe the fat content of foods should be used with the names of standardized foods. Some of the comments suggested that these terms be allowed in conjunction with the names of standardized foods, even when the resulting food no longer complies with the standard.

This is an important issue that has ramifications for all nutrient content claims. Accordingly, FDA has prepared

a separate document on this issue. It is published elsewhere in this issue of the **Federal Register.**

C. Misbranding

Proposed § 101.25(g), which was numbered as § 101.25(d) in the cholesterol tentative final rule (55 FR 29456), states that any label or labeling that is not in conformity with this section shall be deemed to be misbranded under sections 201(n) and 403(a) of the act. The agency is proposing to retain this provision, redesignated as § 101.62(e) and modified to include authority under section 403(r) of the act.

V. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VI. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354). FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register.** The agency requests comments on the RIA.

VII. Effective Date

FDA notes, however, that in section 10(a)(3)(B) of the 1990 amendments, Congress provides that if the Secretary of Health and Human Services (the Secretary), and by delegation FDA, finds that requiring compliance with section 403(q) of the act, on mandatory nutrition labeling, or with section 403(r)(2) of the act, on nutrient content claims, 6 months after publication of the final rules in the **Federal Register** would cause undue economic hardship, the Secretary may delay the application of these sections for no more than 1 year. In light of the agency's tentative findings in its regulatory impact analysis that compliance with the 1990 amendments by May 8, 1993, will cost $1.5 billion, and that 6 month and 1 year extensions of that compliance date will result in savings that arguably outweigh the lost benefits, FDA believes that the question of whether it can and should provide for an extension of the effective date of sections 403(q) and (r)(2) of the act is squarely raised.

FDA has carefully studied the language of section 10(a)(3)(B) of the 1990 amendments and sees a number of questions that need to be addressed. The first question is the meaning of "undue economic hardship." FDA recognizes that the costs of compliance with the new law are high, but those costs derive in large measure from the great number of labels and firms involved. The agency questions whether the costs reflected in the aggregate number represent "undue economic hardship." Therefore, FDA requests comments on how it should assess "undue economic hardship." Should it assess this question on a firm-by-firm basis, as was provided in the bill that passed the House Committee on Energy and Commerce (H. Rept. 101–538, 101st Cong., 2d sess., 24 (1990)), an industry-by-industry basis, or should it assess this question on an aggregate basis? If the agency should take the latter approach, comments should provide evidence that would permit the agency to make a determination that there is "undue economic hardship" for most companies. FDA also points out that assessing hardship on a firm-by-firm basis would likely be extremely burdensome because of the likely number of requests.

FDA will consider the question of the meaning and appropriate application of section 10(a)(3)(B) of the 1990 amendments as soon as possible after the comment period closes. The agency intends to publish a notice in advance of any final rule announcing how it will implement this section to assist firms in planning how they will comply with the act. The early publication of this notice is to assist firms in avoiding any unnecessary expenses that could be incurred by trying to comply with a compliance date that may cause "undue economic hardship."

VIII. Comments

Interested persons may, on or before February 25, 1991, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

In accordance with section 3(b)(1)(B) of the 1990 amendments, FDA must issue by November 8, 1992, final regulations permitting nutrient content claims for fat and cholesterol. If the agency does not promulgate final regulations by November 8, 1992, section 3(b)(2) of the 1990 amendments provides that the regulations proposed in this document shall be considered as the final regulations. The agency has determined that 90 days is the maximum time that it can provide for the submission of comments and still meet this statutory timeframe for the issuance of final regulations. Thus, the agency is advising that it will not consider any requests under 21 CFR 10.40(b) for extension of the comment period beyond February 25, 1992. The agency must limit the comment period to no more than 90 days to assure sufficient time to develop a final rule based on this proposal and the comments it receives.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

§ 101.25 [Removed]

2. Section 101.25 *Labeling of foods in relation to fat and fatty acid and cholesterol content* is removed.

3. Section 101.62 is added to subpart D to read as follows:

§ 101.62 Nutrient content claims for fat, fatty acid, and cholesterol content of foods.

(a) *General requirements.* A claim about the level of fat, fatty acid, and cholesterol in a food may only be made on the label and in the labeling of the food if:

(1) The claim uses one of the terms defined in this section in accordance with the definition for that term;

(2) The claim is made in accordance with the general requirements for nutrient content claims in § 101.13; and

(3) The food for which the claim is made is labeled in accordance with § 101.9 or, where applicable, § 101.36.

(b) *Fat content claims.* (1) The terms "fat free," "free of fat," "no fat," "zero fat," "nonfat" "trivial source of fat," "negligible source of fat," or "dietarily insignificant source of fat" may be used on the label or in labeling of a food provided that:

(i) The food contains less than 0.5 gram of fat per reference amount customarily consumed and per labeled serving size;

(ii) The food contains no added ingredient that is a fat or oil; and

(iii) As required in § 101.13(e)(2), if the food meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to lower fat content, it is labeled to disclose that fat is not usually present in the food (e.g., "broccoli, a fat-free food").

(2) The terms "low fat," "low in fat," "contains a small amount of fat," "low source of fat," or "little fat" may be used on the label or in labeling of foods, except meal-type products as defined in § 101.13(l), provided that:

(i) The food contains 3 grams or less of fat per reference amount customarily consumed, per labeled serving size, and per 100 grams of food; and

(ii) If the food meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to lower fat content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches (e.g., "frozen perch, a low fat food").

(3) The terms defined in paragraph (b)(2) of this section may be used on the label or in labeling of a meal-type product as defined in § 101.13(l) that:

(i) The product contains 3 grams or less of fat per 100 grams; and

(ii) If the product meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to lower fat content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches.

(4) The terms "reduced fat," "reduced in fat," or "fat reduced" may be used on the label or in labeling of a food, except meal-type products as defined in § 101.13(l), provided that:

(i) The food has been specifically formulated, altered, or processed to reduce its fat content by 50 percent or more, with a minimum reduction of more than 3 grams per reference amount customarily consumed and per labeled serving size, from the reference food that it resembles and for which it substitutes as defined in § 101.13 (j)(1)(i) and (j)(1)(ii); and

(ii) As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the fat has been reduced; the identity of the reference food; and quantitative information comparing the level of fat in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g., "Reduced fat—50 percent less fat than our regular brownie. Fat content has been reduced from 8 grams to 4 grams per serving").

(5) A comparative claim using the term "less" may be used on the label or in labeling of a food, including meal-type products as defined in § 101.13(l), provided that:

(i) The food contains at least 25 percent less fat, with a minimum reduction of more than 3 grams per reference amount customarily consumed and per labeled serving size, from the reference food that it resembles and for which it substitutes as defined in § 101.13 (j)(1)(i), (j)(1)(ii), and (j)(1)(iii); and

(ii) As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the fat has been reduced; the identity of the reference food; and quantitative information comparing the level of fat in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g. "This pound cake contains 40 percent less fat than our regular pound cake. Fat content has been lowered from 10 grams to 6 grams per serving.").

(6) The term "____ percent fat free" may be used on the label or in labeling of a food provided that:

(i) The food meets the criteria for "low fat" in paragraph (b)(2) or (b)(3) of this section.

(ii) The label or labeling discloses the amount of total fat per serving (as declared on the label) of the food expressed to the nearest 1/2 gram. When the total fat content is less than 0.5 grams per serving, the amount may be declared as "0." Such disclosure shall appear in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) and in type size that shall be no less than one half the size of the type used for such claim.

(iii) The percent of reduction and the words "fat free" are in uniform type size.

(iv) A claim for "100 percent fat free" meets all criteria for "fat free" in paragraph (b)(1) of this section.

(c) *Fatty acid content claims.* The label or labeling of foods that bear claims with respect to the level of saturated fat shall disclose the level of total fat and cholesterol in the food in immediate proximity to such claim each time the claim is made and in type that shall be no less than one-half the size of the type used for the claim with respect to the level of saturated fat. Declaration of cholesterol content may be omitted when the food contains less than 2 milligrams of cholesterol per labeled serving size.

(1) The terms "low in saturated fat," "low saturated fat," "contains a small amount of saturated fat," "low source of saturated fat," or "a little saturated fat" may be used on the label or in labeling of a food, except meal type products as defined in § 101.13(l), provided that:

(i) The food contains 1 gram or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size, and not more than 15 percent of calories from saturated fatty acids.

(ii) If a food meets these conditions without benefit of special processing, alteration, formulation, or reformulation to lower saturated fat content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches (e.g., "raspberries, a low saturated fat food").

(2) The terms defined in paragraph (c)(1) of this section may be used on the label or in labeling of a meal-type product as defined in § 101.13(l) provided that:

(i) The product contains 1 gram or less of saturated fatty acids per 100 grams of food; and

(ii) If the product meets these conditions without the benefit of special processing, alteration, formulation, or reformulation to lower saturated fat content, it is labeled to clearly refer to all foods of its type and not merely to the particular brand to which the label attaches.

(3) The terms "reduced saturated fat," "reduced in saturated fat," or "saturated fat reduced" may be used on the label or in labeling of a food, except meal-type products as defined in § 101.13(l), provided that:

(i) The food has been specifically formulated, altered, or processed to reduce its saturated fatty acid content by 50 percent or more, with a minimum reduction of more than 1 gram per reference amount customarily consumed and per labeled serving size from the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i) and (j)(1)(ii); and

(ii) As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the saturated fat was reduced; the identity of the reference food; and quantitative information comparing the level of saturated fat in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g., "Reduced saturated fat. Contains 50 percent less saturated fat than the national average for nondairy creamers. Saturated fat reduced from 3 grams to 1.5 grams per serving").

(4) A comparative claim using the term "less" may be used on the label or in labeling of a food, including meal-type products as defined in § 101.13(l), provided that:

(i) The food contains at least 25 percent less saturated fat with a minimum reduction of more than 1 gram per reference amount customarily consumed and per labeled serving size, from the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i), (j)(1)(ii), and (j)(1)(iii); and

(ii) As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the saturated fat was reduced; the identity of the reference food; and quantitative information comparing the level of saturated fat in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g., "Brand Y crackers contains 40 percent less saturated fat than our regular Brand X crackers. Brand Y contains 6 grams saturated fat; Brand X contains 10 grams saturated fat.").

(d) *Cholesterol content claims.* (1) The terms "cholesterol free," "free of cholesterol," "zero cholesterol," "no cholesterol," "trivial source of cholesterol," "negligible source of cholesterol," or "dietarily insignificant source of cholesterol" may be used on the label or in labeling of a food provided that:

(i) For foods that contain 11.5 grams or less of total fat per reference amount customarily consumed, per labeled serving size, and per 100 grams of food:

(A) The food contains less than 2 milligrams of cholesterol per reference amount customarily consumed and per labeled serving size;

(B) The food contains 2 grams or less of saturated fat per reference amount customarily consumed and per labeled serving size;

(C) As required in § 101.13(e), if the food contains less than 2 milligrams of cholesterol per reference amount customarily consumed and per labeled serving size without the benefit of specia1 processing, alteration, formulation, or reformulation to lower cholesterol content, it is labeled to disclose that cholesterol is not usually present in the food (e.g., "applesauce, a cholesterol-free food").

(ii) For foods that contain more than 11.5 grams of total fat per reference amount customarily consumed, per labeled serving size, or per 100 grams of food:

(A) The food contains less than 2 milligrams of cholesterol per reference amount customarily consumed and per labeled serving size;

(B) The food contains 2 grams or less of saturated fat per reference amount customarily consumed and per labeled serving size;

(C) The label or labeling discloses the level of total fat in a serving (as declared on the label) of the food. Such disclosure shall appear in immediate proximity to such claim preceding the referral statement required in § 101.13(g) in type that shall be no less than one-half the size of the type used for such claim. If the claim appears on more than one panel, the disclosure shall be made on each panel except for the panel that bears nutrition labeling. If the claim appears more than once on a panel, the disclosure shall be made in immediate proximity to the claim that is printed in the largest type; and

(D) As required in § 101.13(e), if the food contains less than 2 milligrams of cholesterol per reference amount customarily consumed and per labeled serving size without the benefit of special processing, alteration, formulation, or reformulation to lower cholesterol content, it is labeled to disclose that cholesterol is not usually present in the food (e.g., "Canola oil, a cholesterol-free food, contains 14 grams of fat/serving"); or

(E) If the food contains less than 2 milligrams of cholesterol per reference amount customarily consumed and per labeled serving size only as a result of special processing, alteration, formulation, or reformulation, the amount of cholesterol is substantially less (i.e., meets requirements of paragraph (d)(5)(i)(A) of this section) than the food for which it substitutes as specified in § 101.13(d) that has a significant (i.e., 5 percent or more) market share. As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the cholesterol was reduced; the identity of the reference food; and quantitative information comparing the level of cholesterol in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g., Cholesterol free margarine, contains 100 percent less cholesterol than butter. Contains no cholesterol compared with 30 milligrams in one serving of butter. Contains 11 grams of fat per serving.")

(2) The terms "low in cholesterol," "low cholesterol," "contains a small amount of cholesterol," "low source of cholesterol," or "little cholesterol" may be used on the label or in labeling of a food, except meal type products as defined in § 101.13(1), provided that:

(i) For foods that contain 11.5 grams or less of total fat per reference amount customarily consumed, per labeled serving size, and per 100 grams of food:

(A) The food contains 20 milligrams or less of cholesterol per reference amount customarily consumed, per labeled serving size, and per 100 grams of food;

(B) The food contains 2 grams or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size;

(C) As required in § 101.13(e), if the food contains 20 milligrams or less of cholesterol per reference amount customarily consumed, per labeled serving size, and per 100 grams of food without the benefit of special processing, alteration, formulation, or reformulation to lower cholesterol content, it is labeled to clearly refer to all foods of that type and not merely to the particular brand to which the label attaches (e.g., "lowfat cottage cheese, a low cholesterol food").

(ii) For foods that contain more than 11.5 grams of total fat per reference amount customarily consumed, per labeled serving size, or per 100 grams of food:

(A) The food contains 20 milligrams or less of cholesterol per reference amount customarily consumed, per labeled serving size, and per 100 grams of food;

(B) The food contains 2 grams or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size;

(C) The label or labeling discloses the level of total fat in a serving (as declared on the label) of the food. Such disclosure shall appear in immediate proximity to such claim preceding the referral statement required in § 101.13(g) in type that shall be no less than one-half the size of the type used for such claim. If the claim appears on more than one panel, the disclosure shall be made on each panel except for the panel that bears nutrition labeling. If the claim is made more than once on a panel, the disclosure shall be made in immediate proximity to the claim that is printed in the largest type; and

(D) As required in § 101.13(e)(2), the food contains 20 milligrams or less of cholesterol per reference amount customarily consumed, per labeled serving size, and per 100 grams of food without the benefit of special processing, alteration, formulation, or reformulation to lower cholesterol content, it is labeled to clearly refer to all foods of that type and not merely to the particular brand to which the label attaches; or

(E) If the food contains 20 milligrams or less of cholesterol only as a result of special processing, alteration, formulation, or reformulation, the amount of cholesterol is substantially less (i.e., meets requirements of paragraph (d)(5)(i)(A) of this section) than the food for which it substitutes as specified in § 101.13(d) that has a significant (i.e., 5 percent or more) market share. As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the cholesterol has been reduced; the identity of the reference food; and quantitative information comparing the level of cholesterol in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g., "Low cholesterol peanut butter sandwich crackers, contains 83 percent less cholesterol than our regular peanut butter sandwich crackers. Cholesterol lowered from 30 milligrams to 5 milligrams per serving, contains 13 grams of fat per serving.").

(3) The terms listed in paragraph (d)(2) of this section may be used on the label or in labeling of a meal-type product as defined in § 101.13(1) provided that the product meets the requirements of paragraph (d)(2) of this section except that the determination as to whether paragraph (d)(2)(i) or (d)(2)(ii) of this section applies to the product will be made only on the basis of whether the product contains 11.5 grams or less of fat per 100 grams of food, the

requirement in paragraphs (d)(2)(i)(A) and (d)(2)(ii)(A) of this section shall be limited to 20 milligrams of cholesterol per 100 grams, and the requirement in paragraphs (d)(2)(i)(B) and (d)(2)(ii)(B) of this section shall be modified to require that the food contain 2 grams or less of saturated fat per 100 grams rather than per reference amount customarily consumed and per labeled serving size.

(4) The terms "reduced cholesterol," "reduced in cholesterol" or "cholesterol reduced" may be used on the label or in labeling of a food or a food that substitutes for that food as specified in § 101.13(d), except meal type products as defined in § 101.13(l), provided that:

(i) For foods that contain 11.5 grams or less of total fat per reference amount customarily consumed, per labeled serving size, and per 100 grams:

(A) The food has been specifically formulated, altered, or processed to reduce its cholesterol content by 50 percent or more, with a minimum reduction of more than 20 milligrams per reference amount customarily consumed and per labeled serving size from the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i) and (j)(1)(ii);

(B) The food contains 2 grams or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size; and

(C) As required in § 101.13(j)(2) for relative claims, the percent that the cholesterol has been reduced; the identity of the reference food; and quantitative information comparing the level of cholesterol in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii).

(ii) For foods that contain more than 11.5 grams of total fat per reference amount customarily consumed, per labeled serving size, or per 100 grams of food:

(A) The food has been specifically formulated, altered, or processed to reduce its cholesterol content by 50 percent or more, with a minimum reduction of more than 20 milligrams per reference amount customarily consumed and per labeled serving size, from the reference food (as defined in § 101.13(j)(1)(i) and (j)(1)(ii)) that it resembles and for which it substitutes as specified in § 101.13(d) that has a significant (i.e., 5 percent or more) market share;

(B) The food contains 2 grams or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size;

(C) The label or labeling discloses the level of total fat in a serving (as declared on the label) of the food. Such disclosure shall appear in immediate proximity to such claim preceding the referral statement required in § 101.13(g) in type that shall be no less than one-half the size of the type used for such claim. If the claim appears on more than one panel, the disclosure shall be made on each panel except for the panel that bears nutrition labeling. If the claim is made more than once on a panel, the disclosure shall be made in immediate proximity to the claim that is printed in the largest type; and

(D) As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the cholesterol has been reduced; the identity of the reference food; and quantitative information comparing the level of cholesterol in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii).

(5) A comparative claim using the term "less" may be used on the label or in labeling of a food or a food that substitutes for that food as specified in § 101.13(d), including meal-type products as defined in § 101.13(1), provided that:

(i) For foods that contain 11.5 grams or less of total fat per reference amount customarily consumed, per labeled serving size, and per 100 grams:

(A) The food contains at least 25 percent less cholesterol, with a minimum reduction of more than 20 milligrams per reference amount customarily consumed and per labeled serving size, from the reference food that it resembles and for which it substitutes as defined in § 101.13(j)(1)(i), (j)(1)(ii), and (j)(1)(iii);

(B) The food contains 2 grams or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size; and

(C) As required in § 101.13(j)(2) for relative claims, the percent that the cholesterol was reduced; the identity of the reference food; and quantitative information comparing the level of cholesterol in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii).

(ii) For foods that contain more than 11.5 grams of total fat per reference amount customarily consumed, per labeled serving size, or per 100 grams of food:

(A) The food contains at least 25 percent less cholesterol, with a minimum reduction of 20 milligrams per reference amount customarily consumed and per labeled serving size, from the reference food as defined in § 101.13(j)(1)(i), (j)(1)(ii), and (j)(1)(iii) that it resembles and for which it substitutes as specified in § 101.13(d) that has a significant (i.e., 5 percent or more) market share;

(B) The food contains 2 grams or less of saturated fatty acids per reference amount customarily consumed and per labeled serving size;

(C) The label or labeling discloses the level of total fat in a serving (as declared on the label) of the food. Such disclosure shall appear each time the claim is made, in immediate proximity to such claim preceding the referral statement required in § 101.13(g) in type that shall be no less than one-half the size of the type used for such claim. If the claim appears on more than one panel, the disclosure shall be made on each panel except for the panel that bears nutrition labeling. If the claim is made more than once on a panel, the disclosure shall be made in immediate proximity to the claim that is printed in the largest type; and

(D) As required in § 101.13(j)(2) for relative claims, the percent (or fraction) that the cholesterol was reduced; the identity of the reference food; and quantitative information comparing the level of cholesterol in the product per labeled serving size with that of the reference food that it replaces are declared in immediate proximity to the most prominent such claim as defined in § 101.13(j)(2)(ii) (e.g., "This pound cake contains 30 percent less cholesterol than our regular pound cake. Cholesterol lowered from 45 milligrams to 30 milligrams per serving. Contains 12 grams of fat per serving.").

(e) *Misbranding.* Any label or labeling containing any statement concerning fat, fatty acids, or cholesterol that is not in conformity with this section shall be deemed to be misbranded under sections 201(n), 403(a), and 403(r) of the Federal Food, Drug, and Cosmetic Act.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

BILLING CODE 4160-01-M

21 CFR Part 101

[Docket No. 84N-153A]

RIN 0905-AD08

Food Labeling: "Cholesterol Free," "Low Cholesterol," and "___ Percent Fat Free" Claims

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to amend its food labeling regulations to define "cholesterol free" and "low cholesterol" and to provide for the proper use of these terms and the term "___ percent fat free." The proposed rule is intended to ensure that these terms are not used in a manner that is misleading to consumers. In this document, FDA is also responding to the comments that it received in response to its tentative final rule on cholesterol claims (55 FR 29456, July 19, 1990) that pertain to use of the terms "cholesterol free" (including "no cholesterol" and "free of cholesterol") and "low cholesterol."

DATES: Written comments by January 27, 1992. The agency is proposing that any final rule that may be issued based upon this proposal become effective 30 days following its publication.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Virginia L. Wilkening, Center for Food Safety and Applied Nutrition (HFF-204), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-245-1561.

SUPPLEMENTARY INFORMATION:

I. Background

FDA has had a long interest in the proper labeling of foods with information on fat and cholesterol content. FDA's policies have reflected contemporary knowledge on the effect of these food components on health.

Because there was a lack of agreement on the relationship between fat and cholesterol and good health at the time the agency's current regulations were adopted, FDA limited the amount of information that could be provided on the food label about these food components. The relevant regulations are 21 CFR 101.9(c)(6) (formerly 21 CFR 1.17), which requires that the fat content of a food be included in the nutrition label (38 FR 2132, January 19, 1973; and amended at 38 FR 6951, March 14, 1973), and 21 CFR 101.25 (formerly 21 CFR 1.18) (42 FR 14302, March 15, 1977), which provides for the voluntary listing of cholesterol and fatty acid content as part of the food's nutrition label. No other information on fat or cholesterol content is permitted.

In 1986, however, with the emergence of a consensus that limiting dietary cholesterol would contribute to good health, FDA published a proposal to define terms that describe the cholesterol content of foods, including "cholesterol free" and "low cholesterol" (51 FR 42584, November 25, 1986). FDA also proposed to require that whenever these or other terms describing cholesterol content are used on the label, the cholesterol and fatty acid content of the food must be declared in the nutrition label.

As part of the Secretary of the Department of Health and Human Services' food labeling initiative, FDA issued a tentative final rule on cholesterol labeling on July 19, 1990 (55 FR 29456). In announcing that FDA would publish this document, Secretary Louis W. Sullivan stated: "All of us have been frustrated by the misuse of these terms, and only clear, standardized definitions will help us eliminate misleading claims." (Ref. 1.)

In the document FDA addressed the comments that it had received on the 1986 proposal. Many of the comments requested that FDA limit the amount of fat and saturated fatty acids that could be present in foods on which cholesterol claims are made. FDA agreed with these comments and, in the tentative final rule (55 FR 29456), the agency proposed to limit the fat and saturated fatty acid content of foods bearing such claims.

FDA proposed to limit the use of "cholesterol free" and "low cholesterol" to foods that, in addition to containing the requisite cholesterol levels, contain not more than 5 grams (g) of fat and not more than 2 g of saturated fatty acids per serving. On a dry weight basis, these foods could contain not more than 20 percent fat and not more than 6 percent saturated fatty acids. The agency did not propose to change the requisite cholesterol level for "cholesterol free" foods from the 1986 proposal. However, in the case of "low cholesterol" foods, FDA proposed to change the amount of cholesterol per serving from "less than 20 mg" to "20 mg or less" and to add a second criterion, 0.2 mg or less cholesterol per g of food.

On November 8, 1990, the President signed the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). The 1990 amendments made the most significant changes in food labeling law since the passage of the Federal Food, Drug, and Cosmetic Act of 1938 (the act). The 1990 amendments strengthen the Secretary's food labeling initiative by clarifying FDA's legal authority to require nutrition labeling on foods and by defining the circumstances under which claims may be made about the nutrients in foods. Specifically, the 1990 amendments add section 403(r), which deals with claims on foods, to the act. Section 403(r)(1)(A) of the act states that a food is misbranded if a claim is made on the label or labeling that characterizes the level of any nutrient of the type required to be declared in nutrition labeling unless the claim conforms to the specific requirements of the act.

The 1990 amendments directly affect FDA's July 19, 1990 tentative final rule on cholesterol claims. Because of the magnitude of changes needed in the tentative final rule to bring it into conformity with requirements of the 1990 amendments, the agency is issuing a new proposed rule on cholesterol descriptors elsewhere in this issue of the **Federal Register**. The agency is including in that proposal definitions for fat and fatty acid descriptors because of the interrelationship of these food components and cholesterol in the etiology of cardiovascular disease. The 1990 amendments require that FDA propose new regulations by November 8, 1991, and issue final regulations by November 8, 1992. These regulations will go into effect in May of 1993.

As the rulemaking on cholesterol labeling has proceeded, however, FDA has grown progressively more concerned about the "cholesterol free" ("no cholesterol" or "free of cholesterol"), "low cholesterol," and ___ percent fat free" claims that have appeared in the marketplace. The agency's concerns culminated in May of 1991 in an FDA decision to advise a number of companies that the "no cholesterol" claims that they made on their products were misleading (Refs. 1a through 6). Each of the manufacturers that FDA contacted made a product that, while containing no cholesterol, was high in total fat and bore a picture of a heart or some other representation that implied that the food was particularly good for the heart. FDA advised the firms that their products were misbranded under sections 201(n) and 403(a) of the act (21 U.S.C. 321(n) and 343(a)) because their labels failed to reveal that dietary factors other than cholesterol content play a necessary role in achieving a healthy heart, and that the products were high in fat, and excess fat in the diet is a general health

risk. All of the firms that received letters from FDA agreed to modify their labels.

On June 6, 1991, in a speech given at the 20th Anniversary Conference sponsored by the Center for Science in the Public Interest, the Commissioner of FDA outlined the agency's concerns about "____ percent fat free" claims:

> The high number—often 90 percent, 93 percent, and even 97 percent—linked with a desirable characteristic—"fat free"—leads people to conclude that the food itself promotes good health. It can also lead people to conclude that they can eat as much of it as they want. * * * We believe that this kind of assertion confuses and misleads consumers. Foods that derive a high percentage of their calories from fat should not be making low fat claims.
> (Ref. 7)

The Commissioner called on industry to remove these claims from their products.

In response to FDA's actions, the food industry has expressed concern about what it perceives as a lack of rules regarding cholesterol and "____ percent fat free" claims. Industry has argued that fairness suggests that FDA should provide a set of rules under which such claims may or may not be made before the agency institutes enforcement actions. FDA is addressing these concerns in this proposal.

The agency intends to act on this proposal in an expeditious manner. The agency intends to publish a final rule in this proceeding as quickly as possible, and that that final rule will establish interim rules until the final rule implementing the 1990 amendments is promulgated.

II. Basis for Action

FDA has decided that manufacturers should not be permitted to continue to make misleading "cholesterol free" (including "no cholesterol" and "free of cholesterol"), "low cholesterol," and "____ percent fat free" claims while the rulemaking under the 1990 amendments goes forward. The agency has focused on these claims because of the wide industry use of them, and because of the significant effect that they can have on the public health if misused. Therefore, the agency has tentatively decided to adopt interim regulations that lay out the circumstances in which these claims may be made on the food label. Although "reduced cholesterol" and comparative claims were also proposed in the tentative final rule, they are not being addressed in this document because they are rarely found in the marketplace and have not been identified as a source of misleading claims.

The agency is not proposing these rules because it believes that such rules are a necessary prerequisite to enforcement actions against products that misuse "free" and "low cholesterol" and "____ percent fat free" claims. FDA can and will take actions against products that are misbranded at any time.

FDA is issuing these proposed regulations under sections 201(n), 403(a), and 701(a) of the act, and not under the new sections added by the 1990 amendments. FDA believes that these three provisions provide ample authority for the regulations that it is proposing. Section 403(a) of the act states that a food is misbranded if its labeling is false or misleading in any particular. Section 201(n) of the act states that labeling may be misleading not only because of representations made on or in the labeling, but also to the extent that the labeling fails to bear facts material in light of the representations made or material with respect to the consequences that may result from use of the article. Finally, section 701(a) of the act authorizes the agency to adopt regulations for the efficient enforcement of the act.

Although the agency is not relying on the 1990 amendments for legal authority to adopt these proposed interim regulations (in fact, the regulations that will be adopted under the 1990 amendments will supersede these proposed regulations if they are adopted by the agency), the agency has reviewed this proposal in light of the 1990 amendments. The agency recognizes that these proposed interim regulations do not exactly track the 1990 amendments. However, because the purpose of these proposed regulations, like that of the 1990 amendments, is to assure that certain cholesterol and fat claims are not made in a misleading manner, the agency is satisfied that these proposed regulations are not inconsistent with the 1990 amendments.

As stated above, elsewhere in this issue of the **Federal Register**, FDA is publishing a document on fat, saturated fat, and cholesterol nutrient content claims under the 1990 amendments. FDA plans to publish, if possible, the final rule in that proceeding so that comprehensive rules on nutrient content claims for these nutrients are in place at the same time.

III. The Proposed Regulations

A. Modifications of Section 101.25

FDA is proposing to remove § 101.25(a), (b)(2)(ii), (b)(2)(iii), (c)(1), (c)(2)(i), (c)(2)(iii), (d), and (g) because they are out of date. The agency had proposed to delete these provisions of § 101.25 in its proposed rule on cholesterol descriptors (51 FR 42584). The only comments received on these deletions addressed the deletion of percent of calories from fat in § 101.25(c)(2)(i). FDA responded to these comments in the tentative final rule on cholesterol descriptors (55 FR 29456 at 29469).

FDA is also proposing to revise § 101.25(b), (c), and (h) to reflect these deletions and to add a new paragraph (d) as described below.

B. Cholesterol Claims

FDA is proposing to permit "cholesterol free" and "low cholesterol" claims on foods that meet specific requirements that will ensure that these claims are not used in a misleading manner. These requirements, as proposed in § 101.25(d)(1) and (d)(2), are:

(1) That the food must contain no more than the requisite levels of cholesterol;

(2) That the food must contain 2 g or less of saturated fat per serving;

(3) That the label or labeling must disclose the amount of fat per serving in conjunction with the cholesterol claim; and

(4) That, if a food is inherently free of, or low in, cholesterol, the food must be labeled to refer to all foods of that type and not to a particular brand.

1. Definition

a. *"Cholesterol free".* FDA first proposed that a "cholesterol free" food be defined as one containing less than 2 mg of cholesterol per serving in its proposed rule of November 25, 1986 (51 FR 42584). That discussion is included herein by reference. The agency selected the cutoff of less than 2 mg of cholesterol because that level is biologically and nutritionally insignificant. Moreover, analytical precision below that limit is not possible (51 FR 42584 at 42588). This quantitative amount was carried forward in the agency's tentative final rule on cholesterol descriptors (55 FR 29456). In the tentative final rule, the agency rejected comments to the 1986 proposal suggesting that the level used in defining "cholesterol free" should be changed. Differing comments had recommended both lowering the defined amount to absolute zero and raising it to 5 mg per serving. FDA responded that a zero level could not be detected with analytical certainty, and that raising the level to 5 mg could result in consumption of dietarily significant amounts of

cholesterol when only "cholesterol free" foods were consumed.

In its tentative final rule, FDA advised that it considered that document to contain the final determination of the agency on all substantive issues other than on the threshold levels of fat and saturated fatty acids above which a "cholesterol free" claim would be misleading, and that a comment would need to be very significant to cause the agency to make any changes in the rule other than to the threshold levels. No new evidence on this issue was presented in comments on the tentative final rule. Therefore, FDA has not revised the definition for "cholesterol free."

This rule applies to all the phrases that mean the product has no cholesterol, such as "cholesterol free," "free of cholesterol," "no cholesterol," and "does not have any cholesterol." It is not possible to list here all descriptive phrases that would lead consumers to believe the product had no cholesterol. This regulation is designed to govern all such phrases.

b. *"Low cholesterol".* In its proposed rule of November 25, 1986 (51 FR 42584), FDA proposed to allow the term "low cholesterol" on the label or labeling of foods that contain less than 20 mg of cholesterol per serving. That discussion is included herein by reference. The agency found that foods containing less than 20 mg of cholesterol per serving were generally those that had been identified as useful to persons who want to control or moderate their cholesterol intakes or to maintain their cholesterol intakes at relatively low levels.

Comments submitted to the proposed rule persuaded FDA to modify the proposed definition in its tentative final rule: (1) To change the definition from "less than 20 mg per serving" to "20 mg or less per serving," and (2) to add a second criterion based on density, namely that the food contain 0.2 mg or less of cholesterol per g of food. The first change was made to be consistent with FDA's other definitions for "low," for calories (§ 105.66(c)(1)(i)) and for sodium (§ 101.13(a)(3)), that include the integer in the definition.

FDA made the second change to prevent "low cholesterol" label claims from conveying a misleading impression about the cholesterol content of certain foods. Comments pointed out that a single criterion based on serving size could result in widely recognized "high cholesterol" foods with small serving sizes (e.g., butter, lard, and some processed cheese foods) being labeled as "low cholesterol." These comments stressed that despite their small serving sizes, such foods actually may be consumed frequently and in large amounts, resulting in a substantial total daily intake of cholesterol. In addition, the comments were concerned that a "low cholesterol" claim on such foods could encourage increased consumption of the food, significantly adding to an individual's total cholesterol intake.

The comments to the tentative final rule fully supported the first criterion for "low cholesterol" claims (i.e., that the food should contain 20 mg or less cholesterol per serving). However, several comments requested that the second criterion (i.e., 0.2 milligram per gram (mg/g)) be eliminated. These comments argued that promulgation of a regulation specifying serving sizes would negate the need for the second criterion.

Based on a review of the impact of the agency's proposed rule on serving sizes (55 FR 29517) on content descriptors, the agency has tentatively determined that there continues to be a need for a second criterion based on nutrient density even when FDA's rulemaking on serving sizes is completed (Ref. 8). Accordingly, FDA is carrying forward the second criterion for the definition of "low cholesterol." However, the agency is modifying proposed § 101.25(a)(2)(ii), redesignated as § 101.25(d)(2)(i), to specify the second criterion as 20 mg/100 g of food rather than 0.2 mg/g, an identical amount. The agency believes that expressing the second criterion as per 100 g, rather than as per g, is simpler because it eliminates decimals and makes the amount per serving and per weight identical (i.e., 20 mg of cholesterol per serving and per 100 g).

2. Saturated Fat Thresholds

Several comments to the tentative final rule (55 FR 29456) objected to the saturated fat threshold as well as to the total fat threshold for cholesterol claims. Many of these comments asserted that FDA did not have the legal authority to prohibit truthful claims. They stressed the need for consumer education rather than prohibition of claims. One comment argued that scientific evidence does not show that following dietary guidelines to reduce fat and saturated fat intake will decrease the risk of cardiovascular disease.

FDA believes there is convincing evidence that dietary intake of saturated fatty acids is related to the risk of cardiovascular disease, the reduction of which is one purpose behind this rulemaking to define cholesterol content claims. This belief is supported by the "Surgeon General's Report on Nutrition and Health" which states: "Excessive saturated fat consumption is the major dietary contributor to total blood cholesterol levels" (Ref. 9, p. 11), and by the National Research Council's "Diet and Health" report which found a strong relationship between blood cholesterol levels and the prevalence and incidence of atherosclerotic cardiovascular disease (Ref. 10). Accordingly, the agency believes that it would be misleading for a food that contains a significant amount of saturated fatty acids to make a cholesterol claim and, thereby, to encourage consumers to buy the product for the purpose of reducing their risk of heart disease.

The agency agrees that consumer education programs are necessary to explain the relationship between saturated fat intake and the risk of cardiovascular disease. However, FDA is not persuaded that such programs can effectively reach and be understood by all consumers. A recent FDA consumer survey found that 40 percent of respondents thought that a "cholesterol free" food would also be low in saturated fat, and another 20 percent were not sure what the claim implies about saturated fat content (Ref. 11). The survey found that consumers are interested in cholesterol content claims because they believe that eating foods with no or low cholesterol will have a significant effect on their blood cholesterol levels and on their chances of developing heart disease (Ref. 11). These findings lead FDA to conclude that a significant number of consumers are likely to perceive that a food that bears a cholesterol content claim will help to lower blood cholesterol levels and to reduce the risk of heart disease. In point of fact, foods containing little or no cholesterol can contain saturated fats at levels that can contribute to high blood cholesterol which, in turn, can contribute to atherosclerotic cardiovascular disease (Refs. 9 and 10). Accordingly, FDA continues to believe that to ensure that cholesterol content claims do not mislead consumers, it is necessary to permit their use only when the foods also contain levels of saturated fats that are below a specified threshold level.

The agency, therefore, is proposing in § 101.25(d)(1)(ii) and (d)(2)(ii) to prohibit the use of "cholesterol free" and "low cholesterol" claims, respectively, on foods that contain more than 2 g of saturated fatty acids.

3. Threshold Level for Saturated Fat

Many comments suggested changing the threshold levels for saturated fatty acids. The agency had proposed levels of 2 g or less per serving and 6 percent or less saturated fat on a dry weight basis. These values were based on

calculations of the maximum amount of saturated fat that could be present in foods bearing cholesterol claims if a person consuming a typical diet of 16 servings of food per day ate only such foods and was to stay within dietary guidelines of less than 10 percent of calories from saturated fat. Most of the comments were opposed to the percent dry weight criterion. They argued that a dry weight limit would discourage the development of new food products with lower fat and cholesterol contents where water is substituted, in part, for fat. Comments stated that the development of new food technologies to develop more healthful foods would be hampered, and that the dry weight criterion was unnecessary and would unfairly penalize foods that have a high moisture content. A few comments also objected to the 2 g criterion and suggested lower levels, generally related to suggested changes in the definition of "saturated fatty acids."

The agency is persuaded by the arguments contained in the comments that the dry weight criterion is not necessary and is possibly counterproductive to the "Healthy People 2000" objective of increasing the availability of processed food products that are reduced in fat and saturated fat content (Ref. 12). Accordingly, FDA is deleting the dry weight criterion and proposing the 2 g criterion as the sole threshold level for foods bearing a "cholesterol free" or "low cholesterol" claim.

In regard to the definition for "saturated fatty acids," the agency noted in the tentative final rule (55 FR 29469) that the definition was the subject of another rulemaking, namely the proposed rule entitled "Food Labeling; Mandatory Status of Nutrition Labeling and Nutrient Content Revision." FDA recognizes the relationship between the definition of "saturated fatty acids" (i.e., the particular fatty acids that are included in the definition) and the numerical value associated with this threshold level (as well as the values defining "low" and "reduced" saturated fat) and will make adjustments in the proposed threshold level as necessary if it modifies the definition in the nutrition labeling rulemaking. However, for now, FDA is proposing to carry forward the definition of saturated fatty acids in § 101.25(c)(2)(ii) and to adopt a saturated fat threshold of 2 g per serving for "cholesterol free", and "low cholesterol" claims.

4. Total Fat Threshold

Many comments to the tentative final rule (55 FR 29456) were opposed to the use of a total fat threshold that would prohibit cholesterol claims on foods that contain more than 5 g fat per serving and more than 20 percent fat on a dry weight basis. Some of these comments argued that current scientific knowledge does not support an association between the intake of fat and high blood cholesterol, as it does with saturated fatty acid intake, and that therefore a limit on total fat does not pass scientific scrutiny. Comments also asserted that such a threshold would condone the "good food/bad food" concept by requiring individual foods (and even ingredients of foods), rather than the total diet, to meet dietary guidelines of less than 30 percent of calories from fat.

A few comments argued that even though FDA surveys show that many consumers believe that cholesterol is found in all fats and oils, these findings demonstrate a need for consumer education rather than removal of truthful claims. Such education, the comments suggested, could include declarative statements adjacent to claims informing consumers of the total fat content of the product. Comments also stated that a total fat threshold would be a disincentive to the food industry to formulate low cholesterol and low fat foods, which would hinder the achievement of the "Healthy People 2000" objectives (Ref. 12), as well as international harmonization between the U.S. and Canada. The comments pointed out that Canada only restricts the saturated fatty acid content of foods making cholesterol claims.

FDA does not agree that a threshold for allowing a descriptor supports a "good food/bad food" concept. The agency believes that such a threshold merely restricts the use of descriptors to those foods on which they will not be misleading. However, FDA is persuaded by the comments that a cholesterol claim is not inherently misleading on a food that is high in total fat but low in saturated fatty acids. Accordingly, the agency is deleting the total fat threshold.

5. Disclosure of Fat Content

A "cholesterol free" or "low cholesterol" claim, however, represents and suggests that the product provides a health benefit, and the level of fat in the food has a material bearing on this claim. Excess fat in a food increases the likelihood of cancer, other chronic diseases, and obesity. Thus, a "cholesterol free" or "low cholesterol" claim would be misleading under sections 201(n) and 403(a) of the act if the number of grams of fat in a serving of the food is not presented. Moreover, information on another panel of the food labeling would generally not correct this problem. See *United States* v. *An Article of Food * * * "Manischewitz * * * Diet Thins,"* 377 F. Supp. 746, 749 (E.D.N.Y. 1974).

Therefore, in § 101.25(d)(1)(iii) and (d)(2)(iii), FDA is proposing to require that the amount of total fat in a serving of food appear in immediate proximity to a "cholesterol free" or "low cholesterol" claim, respectively. "Immediate proximity" is defined as immediately adjacent to the claim and with no intervening material. FDA is proposing that if the food contains less than 0.5 g of fat per serving, the amount of fat may be declared as "0." The agency believes that less than 0.5 g is a negligible amount of fat.

6. Foods Inherently Cholesterol Free of, or Low in, Cholesterol

FDA is proposing in § 101.25(d)(1)(iv) to carry forward that part of proposed § 101.25(a)(2)(i) (55 FR 29456) that requires that if a manufacturer wishes to make a "cholesterol free" claim on a food that contains less than 2 mg of cholesterol per serving without the benefit of special processing or reformulation to alter cholesterol content, the food must be labeled as "____, a cholesterol free food" (e.g., "applesauce, a cholesterol free food"). The agency believes that this requirement is necessary to make clear that all foods of that type, and not merely the particular brand to which the labeling attaches, do not contain cholesterol. Placement of the term "cholesterol free" immediately before the name of the food (e.g., "cholesterol free applesauce.) would imply that the food has been altered to reduce cholesterol as compared to other foods of the same type. Such an implication would be false and misleading.

For the same reasons, FDA is proposing a similar provision in § 101.25(d)(2)(iv), based on proposed § 101.25(a)(2)(ii) (55 FR 29456) for "low cholesterol" claims. Under this provision foods that are inherently low in cholesterol will have to be labeled as "____, a low cholesterol food" (e.g., "lowfat cottage cheese, a low cholesterol food").

C. "____ Percent Fat Free" Claims

As stated above, FDA has significant concerns about " percent fat free" claims, and these concerns are reinforced by the comments that FDA has received that suggest that many consumers do not understand this type of claim. Therefore the agency is proposing to prohibit the use of this claim in those circumstances in which it

would be misleading and thus would misbrand the product.

Claims for "____ percent fat free" emphasize how close a food is to being free of fat, that is, to containing no fat. They imply that the food has a very small amount of fat in it, and that the food is useful in structuring a diet that is low in fat. The impression that the claim gives is misleading, however, if the food, despite the percentage calculation, contains a significant amount of fat.

Thus, to ensure that, as the claim implies, the food does in fact contain only a small amount of fat, FDA is proposing to require that such claims can only be made on foods that contain 3 g or less of fat per serving and per 100 g of food. FDA also believes that this level would provide an appropriate basis on which to describe a food as "low fat" or "low in fat." The agency urges that any use of the term "low fat" in labeling be in accordance with these levels. In determining this amount, FDA's starting point was § 101.3(e)(4)(ii), in which FDA defines a measurable amount of an essential nutrient as 2 percent of the U.S. Recommended Daily Allowance (RDA). Although there is no U.S. RDA for fat, most dietary guidance (Refs. 10 and 13) suggests that no more than 30 percent of calories should come from fat. Assuming that the average American consumes 2,350 calories a day (55 FR 29476), the average diet should contain no more than 75 g of fat. Two percent of 75 g is 1.5 g.

The agency is not proposing 1.5 g as the cut off for allowing "____ percent fat free" claims, however, because it believes that to do so would unduly restrict the type of foods that could make such a claim. The agency looked at the distribution of fat in the food supply and found that fat is not ubiquitous. Several food categories, including fruits, vegetables, and grains, are mostly free of fat. To account for this fact, FDA believes that it is reasonable to double the measurable amount of fat to arrive at a content level at which it would be misleading to make a "____ percent fat free" claim. Thus, in § 101.25(d)(3)(i), FDA is proposing to permit such claims only on foods that contain 3 g or less of fat per serving.

The agency believes that in addition to a criterion based on the amount of fat in a serving, a criterion based on density (amount in a given weight of food) is needed to control claims on fat-dense foods that have small serving sizes. Such foods may be consumed frequently resulting in a substantial total daily intake of fat. For example, some powdered coffee whiteners contain less than 3 g of fat per serving but contain 35 g of fat per 100 g of food. In addition, the agency is concerned that "____ percent fat free" claims on such foods could encourage consumers to consume the food in larger amounts and more frequently, significantly adding to the total fat intake in an individual's diet.

A density criterion is consistent with the definition for "low calorie" foods in § 105.66(c)(1)(ii) and the proposed definition discussed above for "low cholesterol" claims. In each of these cases, the second criterion is an amount per 100 g equivalent to the amount per serving. For example, "low calorie" is defined as 40 calories per serving and 0.4 calories per gram. The value of 0.4 calories per gram equals 40 calories per 100 g. Therefore, the definition is also 40 calories per serving and per 100 g. The agency considers this consistency to be helpful to consumers and health professionals in being able to recall and use the definitions. Accordingly, FDA is proposing in § 101.25(d)(3)(i) that "____ percent fat free" claims be permitted on food containing 3 g or less fat per serving and per 100 g.

Finally, a "____ percent fat free" declaration would be misleading if the number of grams of fat in a serving of the food was not presented in conjunction with the claim. As discussed with respect to the "cholesterol free" claim, under section 201(n) of the act, a food label is misleading if it fails to reveal facts material in light of the representations that are made on the label. Clearly, the actual amount of fat in a food is a material fact when a "____ percent fat free" claim is made. Moreover, that information generally must be presented on the same label panel as the claim. *United States* v. *An Article of Food * * * "Manischewitz * * * Diet Thins," supra.* Therefore, in § 101.25(d)(3)(ii), FDA is proposing to require that the disclosure of the amount of total fat in a serving of food appear in immediate proximity to a "____ percent fat free" claim. FDA is proposing that if the food contains less than 0.5 g of fat per serving, the amount of fat may be declared as "0." The agency believes that less than 0.5 g is a negligible amount of fat.

V. Economic Impact

This proposal defines the terms "cholesterol free" and "low cholesterol" and provides for the proper use of these terms and for the use of "____ percent fat free" claims in the labeling of foods. The costs resulting from this proposed rule are those borne by firms currently using these terms but not as provided for by this proposal. The agency estimates that 3500 labels may need to be redesigned in order to comply with this proposed regulation for an estimated one-time incremental cost of $25 million. Therefore, in accordance with Executive Order 12291, FDA has carefully analyzed the economic effects of this proposal and has determined that the final rule, if promulgated, will not be a major rule as defined by that Order.

FDA, in accordance with the Regulatory Flexibility Act, has considered the effect that this proposal

would have on small entities including small businesses and has determined that, in accordance with section 605(b) of the Regulatory Flexibility Act, that there will be no significant economic impact on a substantial number of small entities.

VI. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VII. Comment Period

Interested persons may, on or before January 27, 1992, submit to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857, written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.25 is amended by revising the section heading, and paragraphs (b), (c), (d), and (h) and by removing and reserving paragraphs (a) and (g) and (h) to read as follows:

§ 101.25 Labeling of food in relation to fat, fatty acid, and cholesterol content.

(a) [Reserved]

(b) A food label or labeling may include a statement of the cholesterol content of the food: *Provided*, That it meets the following conditions:

(1) The food is labeled in accordance with the provisions of § 101.9; and

(2) The cholesterol content, stated to the nearest 5-milligram increment per serving, is declared in nutrition labeling in accordance with the provisions of § 101.9(c)(6)(ii).

(c) A food label or labeling may include information on the fatty acid content of the food: *Provided*, That it meets the following conditions:

(1) The food is labeled in accordance with the provisions of § 101.9; and

(2) The amount of fatty acids, calculated as the triglycerides and stated in grams per serving to the nearest gram, is declared in nutrition labeling in accordance with the provisions of § 101.9(c)(6)(ii). Fatty acids shall be declared in the following two categories, stated with the following headings, in the following order, and displayed with equal prominence:

(i) *Cis, cis*-methylene-interrupted polyunsaturated fatty acids, stated as "Polyunsaturated", and

(ii) The sum of lauric, myristic, palmitic, and stearic acids, stated as "Saturated".

(d) *Descriptors.* (1) The terms "cholesterol free," "free of cholesterol," or "no cholesterol" or phrases that mean the same thing may be used to describe a food provided that:

(i) The food contains less than 2 milligrams of cholesterol per serving;

(ii) The food contains 2 grams or less of saturated fat per serving;

(iii) The label or labeling discloses the amount of total fat per serving of the food expressed to the nearest gram. When the total fat content is less than 0.5 grams per serving, the amount may be declared as "0." Such disclosure shall appear in immediate proximity to such claim; and

(iv) If the food inherently contains less than 2 milligrams of cholesterol per serving without the benefit of special processing or reformulation to lower cholesterol content, it shall be labeled to clearly refer to all foods of that type and not merely to the particular brand to which the label attaches (e.g., "applesauce, a cholesterol free food").

(2) The terms "low cholesterol" or "low in cholesterol" may be used to describe a food provided that:

(i) The food contains 20 milligrams or less of cholesterol per serving and per 100 grams;

(ii) The food contains 2 grams or less of saturated fat per serving;

(iii) The label or labeling discloses the amount of total fat per serving of the food expressed to the nearest gram. When the total fat content is less than 0.5 grams per serving, the amount may be declared as "0." Such disclosure shall appear in immediate proximity to such claim; and

(iv) If the food inherently contains 20 milligrams or less of cholesterol per serving and per 100 grams without the benefit of special processing or reformulation to lower cholesterol content, it shall be labeled to clearly refer to all foods of that type and not merely to the particular brand to which the label attaches (e.g., "lowfat cottage cheese, a low cholesterol food").

(3) The term "____ percent fat free" may be used to describe a food provided that:

(i) The food contains 3 grams or less fat per serving and per 100 grams, and

(ii) The label or labeling discloses the amount of total fat per serving of the food expressed to the nearest gram. When the total fat content is less than 0.5 grams per serving, the amount may be declared as "0." Such disclosure shall appear in immediate proximity to such claim.

* * * * *

(g) [Reserved]

(h) Any food bearing a label or having labeling containing any statement concerning cholesterol, fat, or fatty acids which is not in conformity with this section shall be deemed to be misbranded under sections 201(n) and 403(a) of the Federal Food, Drug, and Cosmetic Act.

Dated: November 4, 1991.

21 CFR Part 130

[Docket No. 91N-0317 et al.]

RIN 0905-AD08

Food Standards: Requirements for Substitute Foods Named by Use of a Nutrient Content Claim and a Standardized Term

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to amend the General Provisions for food standards to prescribe a general definition and standard of identity for substitute foods named by use of a nutrient content claim defined in 21 CFR part 101 (such as "fat free," "low calorie," and "light") in conjunction with a traditional standardized name (for example "reduced-fat sour cream"). FDA is proposing this action in recognition of current national nutrition

goals and the resulting need to allow modified versions of certain standardized foods to bear descriptive names that are meaningful to the consumer. FDA believes that the action proposed herein will promote honesty and fair dealing in the interest of consumers. This proposal applies only to standards of identity and not to standards of fill or quality.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may be issued based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Shellee A. Davis, Center for Food Safety and Applied Nutrition (HFF–414), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–485–0112.

SUPPLEMENTARY INFORMATION:

I. Introduction

One of the main purposes of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) was to establish the circumstances in which claims could be made that describe the nutrient content of food. In response to the 1990 amendments, elsewhere in this issue of the **Federal Register**, FDA is proposing definitions for such nutrient content claims together with general principles and procedures governing their use. A use of nutrient content claims in which there is a great deal of both industry and consumer interest, but that is not addressed in the nutrient content claims document, is as part of the statement of identity of substitutes for standardized foods.

Foods that are subject to food standards, or that substitute for foods that are subject to food standards, make up a substantial portion of the nation's food supply. There is a strong desire among consumers for substitute foods that have been modified to reduce their fat, saturated fat, cholesterol, or sodium levels below those that are required, or that would occur, under existing food standards. This desire has been voiced in consumer comments in related FDA rulemakings and in statements made at public hearings held by the agency in recent years.

Manufacturers have responded to this consumer desire by placing statements on food labels, including the labels of foods that are subject to standards of identity, that describe the products as "reduced fat" or "light." FDA has been concerned about these actions for two reasons. First, as a general matter, because no uniform set of definitions exists for these nutrient content claims, they are being used in an inconsistent manner, which can result in consumers being confused and misled. Second, FDA is concerned because these nutrient content claims are being used in a manner that is not provided for in the standards of identity. Thus, the use of these nutrient content claims has had the effect of undermining confidence in the labeling of standardized foods, and FDA has taken regulatory action against some of these uses.

FDA's objective, however, is to facilitate, not to hinder, consumer's selection of healthful alternative foods. As Congress recognized in adopting the 1990 amendments (see section II. G. of this document), this objective can be fostered by the use of statements regarding the level of certain nutrients in foods. The agency also recognizes that for foods subject to standards of identity, this objective requires action to provide for the use of accurate, easily understood statements of identity that inform consumers about the nutritional characteristics of substitute products. Finally, FDA believes that such action is necessary to ensure that the substitute products are equivalent to the standardized foods that they replace with respect to nutritional quality and similar to them with respect to essential performance and organoleptic characteristics.

Therefore, FDA tentatively concludes that it is appropriate in addressing the use of nutrient content claims in foods in general, to specifically address the naming of foods that substitute for standardized products using nutrient content claims with standardized terms. That is what the agency intends to do in this document.

II. Background on Food Standards and Food Names

A. The Federal Food, Drug and Cosmetic Act of 1938

Congress provided for the establishment of definitions and standards of identity for particular foods in section 401 of the Federal Food, Drug, and Cosmetic Act (the act) of 1938. Congress' original concept of food standards was that there are certain traditional foods that everyone knows, such as bread, milk, and cheese, and that when consumers buy these foods, they should get the foods that they are expecting. Thus, the definitions and standards of identity fixed the content of the food that could be called by a particular name. For example, any food called "bread" has to comply with the definition and standard for that food. Many of the food standards established by FDA were in the form of restrictive recipes that defined the composition of these foods in great detail. As a result, many food manufacturers argued that food standards suppressed competition and stifled innovation.

FDA has promulgated approximately 300 standards of identity under section 401 of the act. These standards are codified in 21 CFR parts 131 through 169. Under the misbranding provisions of section 403 of the act, if a food resembles a standardized food but does not comply with the standard, that food must be labeled as an "imitation."

B. Formal Rulemaking Keeps Standards Behind Technology

Because of the elaborate, formal rulemaking procedures specified for food standards in section 701(e) of the act, many months or years were often required to adopt a standard or to amend one once it had been adopted. As a result, FDA found it almost impossible to keep food standards up-to-date with advances in food technology and nutrition.

C. Food Additive Provisions and the "Safe and Suitable" Policy

Before enactment of the Food Additives Amendment of 1958 and the Color Additive Amendments of 1960, virtually all ingredients of standardized foods were prescribed individually by name. These amendments, however, included requirements for the premarket approval of new food and color additives and, thus, eliminated questions of safety from the development of food standards.

As a result, FDA felt that it could depart from the strict recipe approach to food standards. In the standard for frozen raw breaded shrimp, which was issued in 1961 (now codified at 21 CFR 161.175), instead of specifying each individual ingredient allowed in the breading, FDA simply provided for "safe and suitable" batter and breading ingredients.

FDA defined "safe and suitable" in 21 CFR 130.3(d) to mean regulated food additives, color additives, generally recognized as safe substances (GRAS), and other functional ingredients used in conformance with provisions of the act at levels no higher than necessary to achieve the intended functional effect. A number of current standards of identity permit the use of "safe and suitable" ingredients.

D. The 1973 "Common or Usual Names" Policy

In the Federal Register of March 14, 1973 (38 FR 6964), FDA promulgated regulations governing the establishment of "common or usual names" for nonstandardized foods. FDA advised in the proposed rule of June 22, 1972 (37 FR 12327), that new food standards need not be issued if, for certain foods, appropriate labeling would be sufficient to protect the interest of consumers. In such cases, in lieu of a full food standard, the agency would rely instead on the establishment of the common or usual name of the food.

One of the principal benefits of this regulation (now codified at 21 CFR part 102) was that new products and names for them could be adopted by informal notice-and-comment procedures, rather than by the costly and time-consuming process of formal rulemaking under section 701(e) of the act. The new regulation did not prove to be widely applicable, however, because many foods (e.g., ice cream, cheese) are defined not only by ingredient content but also by technical descriptions of methods of manufacture, processing, or storage, which are much more amenable to presentation in a standard of identity.

E. The 1973 "Imitation" Policy

In a further attempt to provide for advances in food technology and thus to give manufacturers relief from the dilemma of either complying with an outdated standard or having to label their new products as "imitation," FDA sought in 1973 to narrow the scope of food standards by adopting the so-called "imitation" policy. Until 1973, there were no objective criteria for the use of the term "imitation." In the Federal Register of August 2, 1973 (38 FR 20702), FDA promulgated 21 CFR 101.3(e), which provides that only nutritionally inferior substitute foods are required to be labeled "imitation."

In its proposed rule of January 19, 1973 (38 FR 2138), FDA noted that vast strides in food technology had been made since the act was enacted in 1938, and that "there are now on the market many new wholesome and nutritious food products, some of which resemble and are substitutes for other, traditional foods. Significantly, it is no longer the case that 'such products are necessarily inferior to the traditional foods for which they may be substituted."

In addressing the nutritional properties of substitute foods in which fat and calories are reduced, FDA stated that since a reduction in fat content or caloric content may well be desirable, such a reduction should not be regarded as nutritional inferiority.

The regulation defined "nutritional inferiority" as any reduction in the content of an essential nutrient that is present at a level of 2 percent or more of the U.S. Recommended Daily Allowance (U.S. RDA), as established in 21 CFR 101.9(c)(7). It also provided that a substitute food would not be deemed to be an imitation if, in addition to not being nutritionally inferior, its label bears a common or usual name that complies with 21 CFR 102.5, or it bears "an appropriately descriptive term that is not false or misleading."

Under this policy, FDA took the position that an appropriately descriptive term included not only a description of the change from the standardized food (for example "reduced fat") but also the fact that the food was a substitute or alternative to a standardized food. FDA felt that it was necessary to include the latter fact to ensure that the consumer was not misled into believing that he or she was buying the traditional food. Thus, a cheddar cheese product in which the fat was reduced (FDA's informal view was that fat had to be reduced by 50 percent for it to be "reduced") had to be called "reduced fat cheddar cheese substitute." Many manufacturers, however, felt that terms such as "substitute" or "alternative" have a derogatory meaning and imply to the consumer that the products are of inferior quality, or that they are less nutritious than the respective standardized foods. The manufacturers felt that consumers would consequently be unwilling to accept and purchase the substitute products.

FDA also took the position that if such a product were labeled without the use of the term "substitute" or "alternative," the product would purport to be the standardized food. Thus, the manufacturer could seek to amend the standards of identity to provide for the modified food. However, if the manufacturers marketed the food without doing so, the product was subject to regulatory action as a misbranded food.

F. The 1989 Advance Notice of Proposed Rulemaking

In the Federal Register of August 8, 1989 (54 FR 32610), FDA published an advance notice of proposed rulemaking (ANPRM) concerning food labeling. The agency requested public comments on several matters, including "whether to formally define commonly used food nutrient content claims and/or reconsider the use of standards of identity for foods." The notice stated that because of the growing public interest in eating healthy foods, manufacturers had begun to place statements on their labels that described their products in such ways as "low in _____" and "reduced _____." FDA had found, however, that these nutrient content claims were not always used in honest or consistent ways. To bring some order to the marketplace and to ensure that consumers are not misled, FDA stated that it was developing a series of nutrient content claims for use on the labels of foods.

G. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101–535). The 1990 amendments make the most significant changes in food labeling and food standards law since passage of the act in 1938. The effect of this legislation is to clarify and strengthen FDA's legal authority to require nutrition labeling on foods and to establish the circumstances under which claims may be made about nutrients in foods. Several provisions of the 1990 amendments relate to the proposal discussed below.

Section 3(a) of the 1990 amendments revised the act by, among other things, adding new paragraph 403(r)(1)(A). This provision states that a food is misbranded if it bears a claim in the label or labeling that either expressly or by implication characterizes the level of any nutrient of the type required by nutrition labeling (i.e., amounts of saturated fat, total fat, cholesterol, sodium, complex carbohydrates, total carbohydrates, sugars, total calories derived from any source and derived from total fat, and various vitamins and minerals), unless such claim has been specifically defined (or otherwise exempted) by regulation, as required by section 403(r)(2)(A)(i) of the act.

Section 3(a) of the 1990 amendments also added new section 403(r)(5)(C) to the act, which states that nutrient content claims that are made with respect to a food because the claim is required by a standard of identity issued under section 401 of the act are not subject to section 403(r)(2)(A)(i). Thus, a nutrient content claim that is part of the name of a standardized food may continue to be used even if the use of the term in the standardized name is not consistent with the definition for the term that FDA adopts, or even if FDA has not defined the term. This exemption was necessary to protect the status of existing standards having names that make a nutrient content claim (such as "low-fat milk"). The

legislative history of the 1990 amendments (Ref. 1, p. 22) reveals that Congress was aware, however, that the Secretary and, by delegation, FDA have the authority to correct this problem by amending the portions of the standards of identity pertaining to food labels to conform with the regulations issued under new section 403(r) of the act.

Section 3(b)(1)(A)(iii) of the 1990 amendments requires that the Secretary issue regulations to define the following terms (unless the Secretary finds that the use of any such terms would be misleading): "Free," "low," "light"/"lite," "reduced," "less," and "high."

Section 7(1) of the 1990 amendments amended 403(i) of the act by striking out the provision that exempted standardized foods from the requirement for full ingredient labeling. Under the pre-1990 amendment provisions of paragraph 403(i) of the act, only those components of standardized foods classified as "optional" had to be declared by their common or usual name on the label, and then only when specifically required by FDA.

Section 8 of the 1990 amendments removed section 401 of the act from the coverage of section 701(e). Thus, FDA may now use informal notice-and-comment rulemaking, rather than formal rulemaking, in adopting new food standards and in amending or repealing existing standards, except for the existing standards for dairy products and maple syrup.

III. Existing Regulations Employing Nutrient Content Claims

FDA has adopted several regulations prescribing nutrient content claims. For example, the regulation on sodium labeling (current 21 CFR 101.13) defines various levels of sodium on a per serving basis as follows: "Sodium free" (less than 5 milligrams), "very low sodium" (35 milligrams or less), "low sodium" (140 milligrams or less), and "reduced sodium" (75 percent reduction for the food as a whole). The agency has also defined "low calorie" and "reduced calorie" foods relating to usefulness in reducing or maintaining caloric intake or body weight (current 21 CFR 105.66), as well as terms such as "sugar free," "sugarless," and "no sugar" (current 21 CFR 105.66(f)).

A number of standards of identity have been established that incorporate the terms "light," "low," "non," or "reduced" in the names of the standards, including: lowfat dry milk (§ 131.123), nonfat dry milk (§ 131.125), nonfat dry milk fortified with vitamins A and D (§ 131.127), lowfat milk (§ 131.135), acidified lowfat milk (§ 131.136), cultured lowfat milk (§ 131.138), light cream (§ 131.155), light whipping cream (§ 131.157), lowfat yogurt (§ 131.203), nonfat yogurt (§ 131.206), low sodium cheddar cheese (§ 133.116), low sodium colby cheese (§ 133.121), lowfat cottage cheese (§ 133.131), nonfat milk macaroni products (139.121), and low-fat cocoa (§ 163.114).

In addition, FDA has issued many temporary marketing permits (TMP's) under terms of § 130.17 for various low-, reduced- and non-fat alternative foods such as light eggnog, nonfat cottage cheese, and light sour cream. By issuing a TMP, FDA expresses its willingness to refrain from instituting regulatory action against a product on the grounds that it does not conform to the applicable standard while market tests are conducted to measure consumer acceptance of the product, identify mass production problems, assess commercial feasibility, and determine whether the standards of identity should be amended to provide for the new food.

IV. The Current Situation

In the August 1989 ANPRM (54 FR 32610), FDA stated that it was aware that manufacturers were using nutrient content claims such as "low in _____" or "reduced _____" on a wide variety of food labels, and that, in the absence of definitions provided by FDA, the nutrient content claims were being used in an inconsistent manner, so that consumers were likely confused or being misled.

The agency is also aware that these nutrient content claims are being applied to products that substitute for foods for which FDA has published standards of identity, particularly dairy products defined in 21 CFR Part 131 (Milk and cream), Part 133 (Cheese and related cheese products), and Part 135 (Frozen desserts), as well as mayonnaise and salad dressings defined in 21 CFR Part 169 (Food dressings and flavorings). By use of nutrient content claims such as "low fat," "reduced fat," or "no fat," these products are represented as containing levels of fat that are below the minimum levels required by the respective standards of identity for the foods for which the products substitute.

As discussed above, the formal rulemaking procedures specified for food standards in section 701(e) of the act have made it difficult to update the many existing food standards. Consequently, certain food standards do not reflect advances in food technology or current knowledge regarding nutrition and health. The most immediate problem is with fat, which was considered to be an economically and nutritionally valuable component of food when the act was enacted in 1938 and which is the basic characterizing ingredient in many foods for which standards have been adopted over the last 50 years, primarily dairy products.

Today, high dietary levels of cholesterol and fat/fatty acids are implicated as significant risk factors in the development of cardiovascular and other chronic diseases. Both "The Surgeon General's Report on Nutrition and Health" (Ref. 2) and the National Academy of Science's report on "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 3) focus on fat consumption by Americans as the primary diet-related risk factor for cardiovascular disease.

Technological developments have brought about new products having a reasonable degree of consumer acceptance that are low or reduced in fat and cholesterol. The inflexibility of the traditional standards system, however, places these and similar products at a disadvantage when they attempt to enter the market because they cannot legally be called by a name that is easily recognized or desired by consumers. For instance, a product called "sour cream" must contain a minimum of 18 percent milkfat, as required by the standard of identity, § 131.160, even though lower fat products are now available.

FDA is aware that the issues discussed in this document, including suggestions for improvements in the food standards system, have been addressed repeatedly for many years by experts and observers both inside and outside the agency (Refs. 4 through 15). The role of food standards was assessed by a committee of the Food and Nutrition Board of the National Academy of Sciences' Institute of Medicine (IOM) as part of a recent study supported by the U.S. Department of Health and Human Services and the U.S. Department of Agriculture. In its report entitled "Nutrition Labeling, Issues and Directions for the 1990's" (Ref. 16), the committee observed that: "In 1990, less skepticism exists about consumers' abilities, aided by informative labeling, to protect themselves against debased or diluted products * * *. Attention is now focused on the consumption of too much fat rather than the possibility that some products will be made using less of an ingredient than was historically considered a valuable constituent. Accordingly, it seems clear to the [IOM] Committee that any system that significantly impedes the marketing of reduced-, low-, and non- or no-fat

substitutes should be examined and, presumably, changed." FDA believes that this is a fair assessment of the current situation.

V. Pending Petitions

The Milk Industry Foundation (MIF), Washington, DC 20006, a trade association representing manufacturers and distributors of dairy products, filed a petition, dated September 12, 1988 (Docket No. 88P-0329), to establish a standard of identity for "light sour cream." MIF believes that establishing a standard of identity for "light sour cream" would promote public health, satisfy consumer demand, and would assure that "light sour cream" has an appropriate reduction in fat content. Since the MIF petition was filed, FDA has received a number of applications from companies desiring to market test "light (or lite) sour cream," and the agency has issued 19 TMP's for the product. FDA received two additional petitions to establish a standard for "light sour cream" from H. P. Hood, Inc. (Docket No. 89P-0105), and Crowley Foods, Inc. (Docket No. 89P-0403), at the time these manufacturers submitted applications to extend their TMP's.

MIF also filed a petition, dated September 16, 1988 (Docket No. 88P-0334), to establish a standard of identity for "light eggnog." MIF stated in its petition that establishing a standard of identity for light eggnog would promote public health, satisfy consumer demand, and would assure that light eggnog products have a significant reduction in fat content. Since the MIF petition was filed, FDA has received a number of applications from companies desiring to market test "light (or lite) eggnog." The agency has issued 33 TMP's for the product. H. P. Hood, Inc., submitted a petition (Docket No. 89P-0329) to establish a standard for "light eggnog" at the time they applied to extend their TMP for this product.

FDA has received a number of letters from firms indicating that they desire to participate in the extended market tests for "light sour cream" and "light eggnog," and FDA has issued letters of approval for participation in the extensions.

The International Ice Cream Association (IICA), Washington, DC 20006, a trade association representing manufacturers and distributors of ice cream and other frozen desserts, and the Public Voice for Food and Health Policy (Public Voice), Washington, DC 20036, a national nonprofit consumer research, education, and advocacy organization, submitted petitions dated February 23 and March 30, 1990, respectively, asking FDA to amend the standard of identity for ice milk to change the name of the food to "reduced fat ice cream" and to establish standards of identity for products designated as "lowfat ice cream" and "nonfat ice cream." The Public Voice petition would, in addition, reduce the maximum milkfat content in the standard of identity for ice milk from 7 percent to 5 percent.

Kraft General Foods, Inc. (KGF), Philadelphia, PA 19103, a manufacturer and distributor of a broad range of food products within the United States, also submitted a petition, on March 14, 1990, to establish a standard of identity for "nonfat ice cream." The Calorie Control Council (CCC), Atlanta, GA 30342, an international association of manufacturers of low-calorie and diet foods and beverages, including manufacturers of a variety of sweeteners and other low-calorie ingredients, submitted a petition, dated March 5, 1990, to add a provision to each of the IICA proposed standards (i.e., "reduced fat ice cream," "lowfat ice cream," and "nonfat ice cream") to permit the use of any safe and suitable sweeteners, including saccharin, aspartame, and acesulfame potassium (acesulfame K), in the foods. IICA submitted another petition, dated March 29, 1990, to expand its February 23, 1990, petition to include a provision in the standard of identity for ice cream (§ 135.110) and in each of its proposed standards to permit the use of safe and suitable sweeteners, as provided in the CCC petition.

On January 22, 1991, FDA published an advanced notice of proposed rulemaking (56 FR 2149) concerning the filing of these petitions to amend the standards for ice cream and ice milk and to establish standards for reduced fat, lowfat, and nonfat ice creams.

FDA is responding to the above petitions in this proposal although FDA will also respond to some portions of the petitions to amend the standards for ice cream and ice milk in a separate proposal to be published at a future date. FDA encourages these petitioners and all interested persons to comment on this proposal and on the other nutrient content claim proposals published elsewhere in this issue of the Federal Register.

VI. Rationale and Legal Issues

A. Appropriateness of the Proposed Action

Questions concerning the naming of foods that are substitutes for standardized foods and concerning the use of standardized terms with nutrient content claims to describe products that substitute for standardized foods have confronted the agency for almost 20 years. In response to FDA's proposed rule on the "imitation" policy published in the Federal Register of January 19, 1973 (38 FR 2138), one comment recommended that the "imitation" regulation should preclude the use of a standardized name in connection with the name of a nonstandardized product (38 FR 20702, 20703). FDA rejected this suggestion, however, on the grounds that it may be necessary to include a standardized name in the name of a substitute food in order to provide the consumer with accurate, descriptive, and fully informative labeling. The agency confirmed this interpretation in the Federal Register of January 19, 1979 (44 FR 3964), stating that the existence of a standard of identity for a particular food does not necessarily preclude the use of the standardized name in connection with the name of a nonstandardized food.

In further commenting on the use of standardized names for substitute foods in the Federal Register of August 19, 1983 (48 FR 37666), FDA again advised that in some cases, it may be reasonable and appropriate to include the name of a standardized food or other traditional food in the name of a substitute food in order to provide the consumer with an accurate description. The agency stated that when this is done, the name of the food must be modified such that the nature of the substitute food is clearly described and is clearly distinguished from the food that it resembles and for which it is intended to substitute. The agency stated that the modification of the traditional or standardized food's name must be descriptive of all differences that are not apparent to the consumer. Thus, the agency concluded, the procedure for naming these foods will depend on the nature of the substitute food and the manner and extent to which it differs from the food it simulates.

As discussed in section III of this document, a number of standards of identity have been established that incorporate the terms "light," "low," "non," or "reduced" in the names of the standards. Thus, the use of nutrient content claims (similar to those discussed herein) in connection with standardized terms is neither new nor unusual.

However, FDA did not have available a uniform set of defined nutrient content claims that could be referenced in a regulation of that provided for their use in a generic sense in connection with standardized terms, nor did it have a mandate from Congress to provide statements regarding the level of these

nutrients in foods "in a manner that facilitates the public's understanding" (Ref. 1, p. 18). New section 403(r) (1) of the act (added by section 3 of the 1990 amendments) provides for the establishment of FDA-defined nutrient content claims on food labels to accurately and truthfully inform consumers about the nutritional content of products complying with the definitions. FDA believes that this section together with section 401 of the act, which gives the agency authority to promulgate definitions and standards of identity if such action will promote honesty and fair dealing in the interest of consumers, and the amendment of section 701(e), which makes it possible to adopt new standards by notice and comment rulemaking, provide the agency with the authority and the means to adopt the new generic standard in proposed § 130.10.

FDA believes that this proposed action is reasonable and appropriate, and that it is needed to provide the consumer with accurate, descriptive, and fully informative labeling that will not only promote honesty and fair dealing in the interest of consumers but will also facilitate achievement of the national nutritional goals. The agency invites comments with respect to the appropriateness and need for the action proposed in this document.

B. Departure From Traditional Policy

FDA is aware that the regulatory approach in proposed § 130.10 represents a departure from the agency's traditional policy with respect to the naming of substitute foods. FDA notes, however, that its policies have always evolved, even in the absence of significant legislative amendments to the act.

For example, in 1953 FDA held that the nondairy product "Chil-Zert" was misbranded under section 403(c) of the act because it was a substitute for ice cream (which was not standardized at the time) but was not labeled as "imitation," even though the package was conspicuously labeled "Not an Ice Cream" and "Contains No Milk or Milk Fat." By 1973, however, when FDA instituted the "imitation" policy, the agency had decided that a nutritionally equivalent substitute for a standardized food need not be labeled "imitation" provided its label bore a common or usual name, or an appropriately descriptive name, that was not misleading. Moreover, FDA also decided that "since a reduction in fat content or calorie content may well be desirable, such a reduction should not be regarded as nutritional inferiority" (38 FR 2138).

FDA believes that recent developments make further changes in FDA's policies appropriate. Through the 1990 amendments, Congress has given FDA the authority to ensure that consumers are given information about the ingredient and nutrient content of virtually all foods and to establish the circumstances under which claims may be made about the levels of nutrients in foods. Thus, the agency can now rely more on labeling requirements, and less on restrictive recipes, in carrying out its mandate to ensure that consumers get the products they expect, and that the nutritional and health-related properties of foods are properly conveyed to the consumer.

VII. FDA Proposal

A. Generic Standard

FDA recognizes that valuable and helpful information concerning the nutrient content of food could be conveyed to consumers if defined nutrient content claims could be used in a consistent and responsible manner in the names of certain substitute foods. A substitute food as defined in proposed § 101.13(d) in the general proposal on nutrient content claims, published elsewhere in this issue of the **Federal Register**, is one that may be used interchangeably with another food that resembles, i.e., organoleptically, physically, and functionally similar to, that food, and is not nutritionally inferior to that food unless labeled as an "imitation."

The agency is also defining in that proposal the terms "free," "low," "light" or "lite," "reduced," and "high." In addition, FDA is proposing to define the terms "very low" (for sodium only) and "source" and to make provision for the use of comparative statements using the terms "less," "fewer," and "more" because the agency has tentatively concluded that they would be useful in helping consumers choose a healthy diet. FDA is also defining the term "modified" in proposed § 101.13(k) to be used in the statement of identity of a food that bears a comparative claim in conformity with the requirements of 21 CFR part 101.

Given these developments and the other developments discussed in this proposal, FDA believes that it is now appropriate for it to set forth general requirements governing the establishment of standards of identity for certain nutritionally equivalent alternate foods. The proposed general requirements in § 130.10 specify the conditions under which aspects of traditional standards and appropriate nutrient content claims may be used to define new standardized foods.

The establishment of individual new standards may be necessary for certain foods, but, in general, the promulgation of a large number of individual regulations would be time-consuming and unnecessarily wasteful of the agency's resources. Consequently, FDA believes that a generic standard applicable to the vast majority of alternate foods offers the most reasonable and effective approach. Proposed § 130.10 describes the conditions under which a variety of substitute foods may use nutrient content claims and standardized names.

B. Existing Standards Using Nutrient Content Claims Not Affected

Currently there are a number of standards, such as lowfat cottage cheese (§ 133.131) in which a nutrient content claim ("lowfat") is already part of the name of the food. The names of such foods would remain unchanged by the regulation proposed in this document. In recognition of the fact that various nutrient content claims have already been incorporated in the names of a number of standardized foods (see listing of such foods in section III of this document), Congress exempted these foods from compliance with the nutrient content claim-provisions of the 1990 amendments (section 403(r)(5)(CC) of the act). FDA points out, however, that these existing standards are subject to amendment to make them consistent with the nutrient content claim definitions that are being proposed in a document published elsewhere in this issue of the **Federal Register**.

C. Substitute Foods Defined by This Proposal

1. Nutrient Content Claims

FDA is proposing in § 130.10 a generic standard of identity that prescribes the conditions under which substitute foods (as defined in proposed § 101.13(d)) that do not comply with a standard of identity defined in 21 CFR parts 131 through 169 because of a deviation that is described by a nutrient content claim, but that do comply with the standard in most other respects, may be named using a nutrient content claim and the standardized term. In § 130.10(a), FDA is proposing that the use of the nutrient content claim to name the new food must comply with the requirements of § 101.13 and with the requirements of the regulations in 21 CFR part 101 that define the particular nutrient content claim that is used.

Proposed § 101.13, which is published elsewhere in this issue of the **Federal Register**, prescribes the general circumstances in which claims that characterize the level of a nutrient in a food may be made on a food label or in labeling. Proposed § 101.13(b) limits the claims that can be used, expressly or by implication, to characterize the level of a nutrient (nutrient content claim) of the type required to be declared in nutrition labeling pursuant to § 101.9 to those that have been defined by FDA regulation.

Moreover, the substitute food must meet the definition for the nutrient content claim that FDA has adopted. For example, to use a "reduced fat" nutrient content claim as part of the statement of identity for a cheddar cheese product, it will not be enough for the product to have slightly less than the minimum milkfat content required by the standard of identity for cheddar cheese (§ 133.113). Rather the product will have to have a significant fat reduction. Proposed § 101.62(b)(4)(i) requires that a food must be specifically formulated, altered, or processed to reduce its fat content by 50 percent or more, with a minimum reduction of more than 3 grams per label serving size and per reference amount customarily consumed, from the reference food that it resembles and for which it substitutes to bear such a claim. Regular cheddar cheese contains 10 grams fat per 30 gram serving. Therefore, if this proposal is adopted, "reduced fat cheddar cheese" will have to contain 5 grams or less fat per serving to comply with these requirements and with § 130.10.

Proposed § 130.10(a) requires that the food comply with the traditional standard in all respect except as described by the nutrient content claim and as provided in paragraphs (b) and (d) of the regulation. These exceptions are discussed below.

A number of the standards in 21 CFR parts 131 through 169 contain several requirements for the standardized foods. FDA realizes that some alternate foods using nutrient content claims may deviate from the standard in more than one aspect. For example, eggnog, as defined in § 131.170, must contain not less than 6 percent milkfat and one or more of the optional egg yolk containing ingredients specified in § 131.170(c), such that the egg yolk solids content is not less than 1 percent by weight of the finished food. A product such as nonfat eggnog would deviate from the standard in that it would contain less than 6 percent milkfat and less than the required amount of egg yolk solids content. FDA is requesting comment concerning how far a product may deviate from a standard and still qualify for use of the standardized name.

2. Serving Size

Elsewhere in this issue of the **Federal Register**, FDA is publishing a reproposal of its serving size regulations (first proposed July 19, 1990 (55 FR 29517)) as part of its food labeling initiative to implement the provisions of the 1990 amendments. To prevent consumer deception as a result of a manufacturer reducing the serving size and thereby the calorie, fat, or sodium content per serving, FDA is proposing in § 101.12, which is published elsewhere in this issue of the **Federal Register**, that the serving size of a substitute product, such as a "low calorie" version of the food, must be based on the same reference amount customarily consumed as that of the regular counterpart food. Thus, any change in the characteristics of the food will be the result of changes in the food and not of changes in the serving size.

3. Presentation of Information

To avoid consumer confusion, FDA believes that the principal display panel of the label should clearly describe the difference between the traditional standardized product and the modified substitute product bearing the standardized term, and that the product should be labeled in accordance with proposed nutrient content claim regulations in proposed § 101.13 and other regulations in part 101 (proposed elsewhere in this issue of the **Federal Register**).

For example, for a reduced fat product to comply with §§ 101.13 and 101.62, a truthful comparative statement must appear in immediate proximity to the most prominent use of the fat claim, stating the percentage difference in fat between the modified product and the traditional standardized product. Proposed § 101.62 also requires the declaration of quantitative information comparing the actual amount of fat in a serving of a reduced fat product as compared to the amount in the traditional standardized product. Thus, the principal display panel of the label of a product such as "reduced fat sour cream" that contains 50 percent less fat than regular sour cream will have to include the statement "contains 50 percent less fat than regular sour cream, fat content has been reduced from 6 grams to 3 grams per serving" in immediate proximity to the most prominent (as defined in § 101.62(b)(2)(ii)) statement of identity.

D. Nutritional Inferiority

FDA is proposing to specifically require in § 130.10(b) that a substitute food named by use of a nutrient content claim and a standardized term not be nutritionally inferior, as defined in § 101.3(e)(4), to the traditional standardized food. For example, a cheddar cheese product containing 33 percent less milkfat than regular cheddar cheese that is nutritionally inferior to cheddar cheese under § 101.3(e) would be subject to the requirements of section 403(c) of the act and thus properly labeled as "imitation cheddar cheese."

In § 101.3(e)(4)(i), FDA defines nutritional inferiority as any reduction in the content of an essential nutrient that is present in the food in a measurable amount. FDA has defined measurable amount of an essential nutrient in a food in § 101.3(e)(4)(ii) as 2 percent or more of the U.S. RDA of protein or any vitamin or mineral listed under current § 101.9(c)(7)(iv) per average or usual serving, or where the food is customarily not consumed directly, per average or usual portion, as established in § 101.9. FDA is proposing in the document on Mandatory Nutrition Labeling, published elsewhere in this issue of the **Federal Register**, to establish Reference Daily Intakes (RDI's) for use in declaring nutrient content in nutrition labeling and to replace the current U.S. RDA's with the RDI's. If FDA adopts that proposal, nutritional equivalence will be based on the established RDI.

Dairy products typically contain a significant quantity of fat-soluble vitamins, such as vitamin A, in the milkfat portion. For example, one serving (30 grams) of cheddar cheese provides 8 percent of the U.S. RDA for vitamin A. A 33-percent reduction in the amount of milkfat in "modified cheddar cheese" also reduces the amount of vitamin A and other fat-soluble vitamins per serving. Therefore, FDA believes that vitamin A and other essential nutrients must be added to restore nutrients to products to ensure that the substitute food is not nutritionally inferior to the standardized food. FDA is proposing to provide for that addition in § 130.10(b). Under this proposal, the addition of nutrients will be reflected in the ingredient statement.

E. Performance Characteristics of Food

FDA believes that consumers expect that a product bearing a standardized name will not only resemble the traditional standardized food but will perform like the traditional standardized food. Consumers may assume that the substitute product can be used interchangeably with the traditional standardized food in all applications.

Therefore, in order not to mislead consumers, FDA is proposing in § 130.10(c) to require that a product bearing the standardized name have similar performance characteristics to the standardized food. FDA is proposing that the performance characteristics on which the substitute food is judged include physical properties (e.g., texture, melting point, freezing point), flavor characteristics (e.g., aroma and taste), functional properties (e.g., body, spreadability), and shelf life.

FDA recognizes, however, that it may not be possible or practical to produce substitute products that perform similarly to the traditional standardized food in all respects. As discussed in section IV of this proposal, many existing standards require certain levels of fat because fat was considered to be a valuable component of food when these standards were established. Reduced fat substitute foods, under proposed § 101.62 (b)(4), must have at least 50 percent of the fat removed. The fat is replaced by one or more other ingredients. Many manufacturers "agree that successful fat reduction typically extends beyond the abilities of one single ingredient. It requires a firm understanding of what fat does in a product, and how those functions can be replicated with nonfat ingredients. This understanding covers three primary arenas: Mouthfeel/textural characteristics, flavor characteristics and functionality/ processing concerns" (Ref. 17, p. 28).

Fats exhibit unique physical properties in a food. The fatty acid composition, crystal formation, melting and solidifying properties, and association with aqueous components of the food are important regarding the various textural properties fat imparts. For example, milkfat is important in ice cream because it inhibits the formation of large ice crystals and provides a smooth texture to the food.

Fats are important carriers for flavor because most food flavors, both natural and artificial, whether inherent in a food or added to a food, are fat soluble. Fats are also major contributors to flavor compound precursors and to functional characteristics. For example, a cheddar cheese substitute "made from milk with increased polyunsaturated fatty acid content does not develop normal flavor or body characteristics" (Ref. 18, 337).

FDA believes that shelf life is another important performance characteristic because the moisture content of a food may increase significantly with the reduction of a component such as fat. The increase in moisture becomes a factor in the microbial stability of products. In a food such as "reduced fat ice cream," the increase in moisture also can lead to the formation of large ice crystals because the higher level of free moisture makes the product less freeze-thaw stable (Ref. 17, p. 40).

Therefore, to assure that consumers are not misled as to the characteristics of the modified product, FDA is also proposing in § 130.10(c) to require that if a product bearing a standardized term does not perform in the same way as the traditional standardized food, the label must include a statement informing the consumer of any significant differences. For example, a reduced fat margarine may not perform the same as margarine for use in frying, and if this proposal is adopted, a statement such as "not recommended for frying purposes" must appear on the label. Under 403(f) of the act, FDA believes that the statement must appear on the label with such conspicuousness and in such terms as to render it likely to be read and understood by the consumer under customary conditions of purchase and use. FDA believes that the statement must appear in the same area of the label as the statement of identity for the modified product so that the consumer will know where to find such information. Therefore, FDA is proposing in § 130.10(c) to require that this statement appear on the principal display panel within the bottom 30 percent of the area of the label panel with appropriate prominence which shall be no less than one-half the size of the most prominent nutrient claim on the panel but no smaller than one-sixteenth of an inch.

The agency tentatively concludes that this information is a material fact under section 201(n) of the act because it bears on the consequence of the use of the article. Accordingly, this information must be communicated to the consumer on the product label or the labeling would be misleading, and the product would be misbranded under section 403(a) of the act. FDA is requesting comments concerning what differences in performance characteristics a modified standardized product may possess and still resemble the standardized food closely enough to be included in that product category.

F. Other Ingredients

1. Ingredients Provided For by Proposed Regulation

FDA believes that the ingredients used in the modified version of the standardized food should be those ingredients provided for by the traditional standard with only those deviations necessary to attain an acceptable finished product that meets the requirements of the nutrient content claim that is used. Therefore, FDA is proposing in § 130.10(d)(1) that ingredients used in the product be those ingredients provided for by the traditional standard except that, in addition, "safe and suitable" ingredients, as defined in 21 CFR 130.3(d), may be used to improve texture, add flavor, prevent syneresis, or extend shelf life so that the product is not inferior in performance characteristics to the traditional standardized food.

If flavors are added to a modified standardized product, the label must comply with § 101.22. According to § 101.22(i), if the label, labeling, or advertising of a food makes any direct or indirect representations with respect to the primary recognizable flavor, by word, vignette (e.g., depiction of a fruit), or other means, or if for any other reason the manufacturer or distributor of a food wishes to designate the type of flavor in the food other than through the statement of ingredients, such flavor shall be considered the characterizing flavor. If the food contains any artificial flavor that simulates, resembles, or reinforces the characterizing flavor, under § 101.22(i), the name of the food on the principal display panel or panels of the label must be accompanied by the common or usual name of the characterizing flavor, in letters not less than one-half the height of the letters used in the name of the food. In addition, the name of the characterizing flavor shall be accompanied by the word or words "artificial" or "artificially flavored," in letters not less than one-half the height of the letters in the name of the characterizing flavor. For example, the name of an artificially butter-flavored light margarine would be "light margarine, artificially flavored" if the labeling implies that the product has a buttery taste. Also, natural and artificial flavors must be declared in accordance with applicable sections of 21 CFR part 101 in the ingredient statement in accordance with proposed § 130.10(f).

2. Use of Similar Ingredients

The provision for the use of safe and suitable ingredients proposed in § 130.10(d)(1) is not intended to allow for the replacement or exchange of any required ingredient or component of a required ingredient in the standardized food with functionally similar ingredients from other sources not provided for by the standard. For example, the standard for sour cream (§ 131.160) states that sour cream contains not less than 18 percent

milkfat. FDA believes that replacing the milkfat in sour cream with vegetable oil to make a product labeled as "cholesterol free sour cream" would be misleading because consumers expect sour cream to be a dairy product. Therefore, FDA is proposing in § 130.10(d)(2) that a required ingredient or component of an ingredient that is specifically required by the traditional standard shall not be replaced or exchanged with a similar ingredient from another source unless the traditional standard provides for the use of such ingredient. Thus, a manufacturer who used vegetable oil to replace or substitute for the milkfat in a modified sour cream product would not be able to take advantage of § 130.10.

FDA realizes that many modified versions of standardized foods may contain a greater percentage of moisture than permitted under the traditional standard because of the water contributed by ingredients with a high water content, such as skim milk. For example, colby cheese as defined in § 133.118 may contain not more than 40 percent moisture. Modified colby cheese containing one-third less fat than regular colby cheese may exceed this moisture limit because less whey is drained from the product during processing. FDA is requesting comment from interested persons concerning the appropriateness of the addition of high moisture ingredients and water to foods as ingredients to replace fat and calories in substitute products. FDA is aware of the recent development of fat analogs and is also requesting comments from interested persons concerning the appropriateness of the use of approved fat analogs to replace the fat in substitutes for standardized foods.

3. Ingredients Prohibited by the Standard

The majority of standards of identity prescribe the ingredients that may be included in a standardized food. However, there are some standards of identity defined in 21 CFR Parts 131 through 169 that specifically prohibit the addition of certain ingredients. For example, the standard for milk chocolate, § 163.130, states that milk chocolate may be spiced, flavored, or otherwise seasoned with one or more of the optional ingredients specified in the standard, other than any such ingredient or combination of ingredients that imparts a flavor that imitates the flavor of chocolate, milk, or butter (§ 163.130(a)). FDA believes that ingredients specifically prohibited by the standard should not be used in a substitute food. Therefore, FDA is proposing in § 130.10(d)(3) that an ingredient or component of an ingredient that is prohibited by the standard as defined in 21 CFR Parts 131 through 169 shall not be added to a substitute food.

G. Nomenclature

1. How Foods Are to be Named

FDA is proposing in § 130.10(e) to provide that the name of a substitute food that complies with § 130.10 is the respective standardized term plus an appropriate defined nutrient content claim (e.g., reduced fat sour cream). If a food meets the requirements of § 130.10, it is itself a standardized food. Therefore, even though it does not meet the requirements of the standard underlying the term included in its name, its name need not include the term "substitute" or "alternate." It does not purport to be the traditional standardized food named by that term. It purports to be a food that satisfies the requirement of the standard in § 130.10. Thus, it is appropriately named by use of only the nutrient content claim and the standardized term.

2. Name That Is To Be Used

FDA believes that foods that comply with any standard in 21 CFR parts 131 through 169 must use that standardized name. For example, cream cheese is defined in 21 CFR 133.134 as a product containing at least 33 percent milkfat by weight of the cream cheese, and the maximum moisture content is 60 percent by weight. Neufchatel cheese (§ 133.162) is a product similar to cream cheese except that the milkfat content is not less than 20 percent but less than 33 percent by weight of the finished food, and the maximum moisture content is 65 percent by weight. A modified cream cheese containing 25 percent less fat than cream cheese complies with the standard for neufchatel cheese. The standardized name "neufchatel cheese" must appear on the principal display panel, but the comparative statement "contains 25 percent less fat than cream cheese" may also appear on the label. FDA believes that the use of comparative labeling in accordance with regulations in part 101 provides the consumer with useful information in the selection of a variety of foods.

H. Ingredient Labeling

FDA is proposing in § 130.10(f)(1) that each of the ingredients used in the food shall be declared on the label as required by applicable regulations in 21 CFR parts 101 and 130. Under § 101.4, all ingredients must be listed by common or usual name in descending order of predominance by weight on either the principal display panel or the information panel.

To assist the consumer in differentiating between the traditional standardized food and the modified version of the standardized food, FDA is proposing in § 130.10(f)(2) that all ingredients added under the "safe and suitable" provision, if not provided for by the traditional standard, as well as permitted ingredients added at levels in excess of those allowed by the traditional standard, must be appropriately identified as such with an asterisk in the ingredient statement. The statement "*Ingredients not in regular _____" (fill in name of the traditional standardized food), or "*Ingredients in excess of amount permitted in regular _____" (fill in name of the traditional standardized food), or both as appropriate, shall immediately follow the ingredient statement in the same type size.

FDA believes that the consumer may be misled to believe that ingredients added to restore nutrients are present in greater amounts than needed to obtain nutritional equivalency if these nutrients are identified with an asterisk in the ingredient statement. Therefore, the agency is proposing that nutrients added to restore nutrients shall not be identified by an asterisk in the ingredient statement.

FDA is requesting comments on the proposed approach to ingredient labeling and on other methods of identifying ingredients not provided for by the traditional standard of identity.

VIII. Noncharacterizing Changes in Standardized Foods

A. Foods Meeting the Requirements of the Standards

When an ingredient or component of an ingredient not specifically required by the standard is removed or reduced (e.g., reduced-cholesterol liquid eggs) or is added (e.g., bread with added oat bran) to a product, the food does not deviate from the established standard of identity. In the former example, the liquid eggs are standardized in § 160.115. The standard does not specifically state how much cholesterol must be present in the eggs, nor does cholesterol contribute any important characteristics to the eggs. Therefore, cholesterol is not a required component of the eggs.

In the latter example, oat bran may be added to bread as one of the optional ingredients included in the standard of identity for bread (§ 136.110). FDA traditionally has considered optional ingredients as nonmandatory ingredients of standardized foods.

unless the standard of identity specifies that one or more of a group of optional ingredients must be present in a food.

FDA specifically considered the issue of the use of nutrient content claims in conjunction with the names of standardized foods in its tentative final rule relating to cholesterol nutrient content claims (55 FR 29456 through 29466, July 19, 1990). In the tentative final rule, FDA stated that defined cholesterol nutrient content claims could be used in association with the names of standardized and nonstandardized foods (except for those foods that are inherently free of, or low in cholesterol). However, the agency noted that for most standardized foods, a change in cholesterol content does not in and of itself change the character and nature of the food such that the food is no longer the standardized food. Thus, the agency said, for most of these foods, the use of nutrient content claims in conjunction with their standardized names will not create common or usual names that will take the food out of the standard for the purposes of § 101.3(e). FDA said that for these foods, the nutrient content claim merely points out the special property (i.e., the cholesterol content) of the food.

FDA further stated in the cholesterol tentative final rule that the use of the same lettering for the nutrient content claim and for the standardized name may be misleading because it would imply that the food is not the standardized food, but a different food that does not meet the requirements of the standard. The agency said that therefore, when cholesterol content claims are used in conjunction with a standardized name, they should be distinguished from that name by type, color, style of lettering, or type size in order to clearly differentiate the identity of the food from the cholesterol claim. FDA received no comments either for or against this policy in response to the tentative final rule.

FDA recognizes that valuable and helpful information concerning the nutrient content of food could be conveyed to consumers if defined nutrient content claims could be used in a consistent and responsible manner in the names of standardized foods. The agency also recognizes that, for the first time, defined nutrient content claims will be available as required by the 1990 amendments.

Because the substitute foods discussed in this proposal may be labeled using nutrient content claims and standardized terms in the statement of identity under proposed § 130.10, the foregoing factors have led FDA to decide to change the position that it set out in the tentative final rule for cholesterol and to tentatively conclude that foods that qualify for the use of a defined nutrient content claim but that still comply with a traditional standard of identity should also be labeled using nutrient content claims and standardized terms in the statement of identity. FDA has been led to this view by two additional factors. First, FDA believes that using inconsistent methods of labeling foods would be confusing to the consumer. Second, FDA believes that this approach provides an additional way to highlight those foods in which the cholesterol level is substantially less than in a food that substitutes for the food (see section 403 (r)(2)(A)(ii)(I) and (r)(2)(A)(iii)(I) of the act and the discussion of those sections in the companion documents on descriptors). Therefore, FDA tentatively concludes that the use of the same lettering for defined nutrient content claims and for the standardized name would not be misleading to consumers.

Thus, under these circumstances, FDA believes that the use of defined nutrient content claims and standardized terms in the statement of identity of a food is appropriate even though the food still complies with the standard of identity. The ingredient statement would reflect any modification of any ingredient used in the food. All claims used must comply with the applicable regulations in 21 CFR part 101 (proposed in separate documents published elsewhere in this issue of the **Federal Register**).

B. Substitute Foods Not Meeting the Requirements of the Standards Because of the Restoration of Nutrients

FDA is advising that substitute foods that do not comply with a traditional standard because nutrients may have been removed coincidental with the removal of a component not required by the standard, and those nutrients are added back to the food to restore nutrients to the levels present in the traditional food, may use a nutrient content claim and the standardized term in association with the statement of identity of the product if the claim complies with the requirements of proposed § 101.13 and with the requirements of the regulations defining the nutrient content claim in 21 CFR part 101. FDA believes that naming foods in this manner will provide for the use of accurate, easily understood statements of identity that inform consumers about the nutrient content of the substitute product. FDA believes that this policy makes sense in light of current national nutritional goals.

FDA believes that the restoration of these nutrients to the food should not be highlighted on the principal display panel or in the statement of identity of the product. In FDA's fortification policy (§ 104.20), the agency stated that it is inappropriate to make any claim or statement on a label or in labeling, other than in a listing of the nutrient ingredients as part of the ingredient statement, that any vitamin, mineral, or protein has been added to a food that replaces a traditional food to avoid nutritional inferiority in accordance with § 101.3(e)(2).

For example, a product such as liquid eggs that has been processed to reduce the cholesterol content may be nutritionally inferior to traditional liquid eggs because some processes to remove cholesterol from a product may inadvertently remove significant quantities of nutrients such as vitamin A. The standard for liquid eggs (§ 160.115) does not provide for the addition of nutrients to the food to restore these nutrients. Without the addition of nutrients to the food, this product would be an imitation food and thus subject to the requirements of section 403(c) of the act in accordance with 21 CFR 101.3(e). FDA believes that a policy that would require such a result would make little sense in light of current dietary guidance. Therefore, FDA tentatively concludes that if nutrients that were inadvertently removed from the liquid eggs during the process to remove cholesterol have been added back to the food, the product may be called "reduced cholesterol liquid eggs" if it complies with nutrient content claim regulations in part 101. All nutrients added to the product would have to be listed in the ingredient statement.

IX. Request for Comment

The agency is requesting comments on the proposed regulation in general, and in particular with respect to the provision concerning the requirement that the performance characteristics of the new product must remain similar to those of the standardized food. FDA encourages the submission of technical data and other information pertaining to the identification and measurement of key performance characteristics for different types of substitute foods, as well as comments about performance properties that are of greatest importance to consumers.

X. Environmental Impact

FDA has determined under 21 CFR 25.24(a) (11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment

nor an environmental impact statement is required.

XI. Economic Impact

FDA has examined the economic implications of the proposed rule pertaining to part 101 requirements as required by Executive Orders 12291, 12612, and the Regulatory Flexibility Act. Executive Order 12291 compels agencies to use cost-benefit analysis as a component of decisionmaking, and Executive Order 12612 requires federal agencies to ensure that federal solutions, rather than state or local solutions, are necessary. Finally, the Regulatory Flexibility Act requires regulatory relief for small businesses where feasible.

Because no marginal costs are expected to be incurred to comply with this proposed regulation, the agency finds that this proposed rule is not a major rule as defined by Executive Order 12291. In accordance with the Regulatory Flexibility Act (Pub. L. 96–354), FDA has also determined that this proposed rule will not have a significant adverse impact on a substantial number of small businesses. Finally, because this regulation is intended to regulate food for interstate trade and individual State regulations may hinder interstate trade, FDA finds that there is no substantial Federalism issue which would require an analysis under Executive Order 12612.

FDA is proposing a change that will provide for consistent use of nutrient content claims for foods that substitute for standardized foods found in 21 CFR parts 131 through 169. This action will codify terms that manufacturers are currently using with TMP's. By establishing a generic standard of identity for modified standardized foods, FDA will avoid having to issue new TMP's or, ultimately, establish individual new food standards. Thus, rather than raise costs to industry and consumers, this action will lower future costs of marketing standardized foods. Rather than addressing a market failure, this action remedies an existing public regulation problem. The benefits of this action include both a reduction of the administrative costs of TMP's and elimination of consumer confusion for terms used to describe standardized and nonstandardized foods.

Options considered include no action, which would cause the agency to continually issue TMP's for each new modified standardized food and, ultimately, to issue separate food standards for each modified food. The other option, which is not appropriate or practicable at this time, would be to eliminate many food standards. Formal rulemaking procedures specified in section 701(e) of the act still apply for amending or repealing food standards for dairy standards and maple syrup under the 1990 amendments. These procedures often require many months or years.

Under existing Federal laws, removal of Federal food standards would allow each state to establish their own standards, which could inhibit interstate trade. Congress, in section 6 of the 1990 amendments, specifically provided for preemption of State laws for foods that are subject to a standard of identity established under section 401 of the act, unless specific exemptions are granted by FDA. Congress' action should help the food industry to conduct its business in an efficient and cost-effective manner, although the agency remains open to consider individual situations.

As firms will not be required to change existing labels, FDA finds that there are no marginal costs of this regulation. This action is also expected to facilitate international trade by providing expanded markets for new products such as low cholesterol and low fat foods that are appropriately named.

XII. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in the brackets in the heading of this document. Comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

List of Subjects in 21 CFR Part 130

Food additives, Food grades and standards.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 130 be amended as follows:

PART 130—FOOD STANDARDS: GENERAL

1. The authority citation for 21 CFR part 130 continues to read as follows:

Authority: Secs. 201, 306, 401, 403, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 336, 341, 343, 371).

2. Section 130.10 is added to subpart A to read as follows:

§ 130.10 Requirements for substitute foods named by use of a nutrient content claim and a standardized term.

(a) *Description.* The foods prescribed by this general definition and standard of identity are those foods that substitute (see § 101.13(d) of this chapter) for a standardized food defined in parts 131 through 169 of this chapter but that do not comply with the standard of identity because of a deviation that is described by a nutrient content claim that has been defined by FDA regulation. The nutrient content claim shall comply with the requirements of § 101.13 of this chapter and with the requirements of the regulations in part 101 of this chapter that define the particular nutrient content claim that is used. The food shall comply with the relevant standard in all other respects except as provided in paragraphs (b) and (d) of this section.

(b) *Nutrient addition.* Nutrients shall be added to the food to restore nutrient levels so that the product is not nutritionally inferior, as defined in § 101.3(e) (4) of this chapter, to the standardized food as defined in parts 131 through 169 of this chapter. The addition of nutrients shall be reflected in the ingredient statement.

(c) *Performance characteristics.* The performance characteristics (e.g., physical properties, flavor characteristics, functional properties, shelf life) of the food shall be similar to those of the standardized food as produced under parts 131 through 169 of this chapter, except that if there is a significant difference in performance characteristics, the label shall include a statement informing the consumer of such difference (e.g. if appropriate, "not recommended for cooking"). Such statement shall appear on the principal display panel within the bottom 30 percent of the area of the label panel with appropriate prominence, in type which shall be no less than onehalf the size of the type used in such claim but no smaller than one-sixteenth of an inch.

(d) *Other ingredients.* (1) Ingredients used in the product shall be those ingredients provided for by the standard as defined in parts 131 through 169 of this chapter and in paragraph (b) of this section, except that safe and suitable ingredients to improve texture, add flavor, prevent syneresis, or extend shelf life may be used so that the product is not inferior in performance characteristics to the standardized food defined in parts 131 through 169.

(2) An ingredient or component of an ingredient that is specifically required by the standard as defined in parts 131 through 169 of this chapter, shall not be replaced or exchanged with a similar ingredient from another source unless the standard, as defined in parts 131 through 169, provides for the addition of such ingredient (e.g., vegetable oil shall not replace milkfat in light sour cream).

(3) An ingredient or component of an ingredient that is specifically prohibited by the standard as defined in parts 131 through 169 of this chapter, shall not be added to a substitute food under this section.

(e) *Nomenclature.* The name of a substitute food that complies with all parts of this regulation is the appropriate nutrient content claim and the applicable standardized term.

(f) *Label declaration.* (1) Each of the ingredients used in the food shall be declared on the label as required by the applicable sections of parts 101 and 130 of this chapter.

(2) Ingredients not provided for, and ingredients used in excess of those provided for, by the standard as defined in parts 131 through 169 of this chapter, shall be identified as such with an asterisk in the ingredient statement, except that ingredients added to restore nutrients to the product as required in paragraph (b) of this section shall not be identified with an asterisk. The statement "*Ingredient(s) not in regular _____" (fill in name of the traditional standardized food) or "*Ingredient(s) in excess of amount permitted in regular _____" (fill in name of the traditional standardized food) or both as appropriate shall immediately follow the ingredient statement in the same type size.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

21 CFR Part 101

[Docket No. 91N-0344]

RIN 0905-AD08

Food Labeling: Use of Nutrient Content Claims For Butter

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to adopt a regulation that will permit the use of nutrient content claims ("descriptors") that are defined by regulation in 21 CFR part 101 to be made for butter. This action is in response to the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). FDA believes that the proposed regulation will provide the consumer with a selection of modified butter products that are informatively labeled and will promote honesty and fair dealing in the interest of consumers.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration; rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Shellee A. Davis, Center for Food Safety and Applied Nutrition (HFF-414), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-485-0112.

SUPPLEMENTARY INFORMATION:

I. Background

A. The Situation With Respect to Butter—The Act of March 4, 1923—Sections 201a and 401 of the Federal Food, Drug, and Cosmetic Act

The Act of August 2, 1886 (24 Stat. 209), defined "butter" as:

* * * the food product usually known as butter, and which is made exclusively from milk or cream, or both, with or without common salt, and with or without additional coloring matter.

The Act of March 4, 1923 (21 U.S.C. 321a) amended the Act of August 2, 1886, by adding the requirement that butter must contain not less than 80 percent by weight of milkfat. FDA has not established any further standards of identity concerning butter because section 401 of the Federal Food, Drug, and Cosmetic Act (the act) (21 U.S.C. 341) specifically states that "no definition and standard of identity and no standard of quality shall be established for * * * butter."

B. Pending Petitions

Johanna Farms, Inc., Flemington, NJ 08822, submitted a citizen petition, dated April 9, 1990 (Docket No. 90P-0141), requesting that FDA establish, by regulation, a common or usual name for

"light butter." Johanna Farms, Inc., is engaged in the dairy business throughout the northeastern and mid-Atlantic United States. Johanna Farms, Inc., stated in its petition that a common or usual name definition for light butter would: (1) Further the public health interest in reduced fat consumption; (2) further the public interest in calorie reduction; (3) respond to consumer demand; (4) provide a term that is truthful, adequately informative, and not misleading; and (5) be consistent with the statutory definition of butter. Because this petition was filed before the passage of the 1990 amendments, FDA is responding to it in this proposal.

FDA published a notice in the Federal Register on March 14, 1991 (56 FR 10906) advising, in part, that it is likely to deny, without prejudice, any health claim or descriptor petition submitted under the 1990 amendments until the agency has promulgated final procedural regulations concerning the submission and content of such petitions. Therefore, FDA has not considered any of the petitions on modified butter products that have been submitted since the passage of the 1990 amendments in developing this proposal. FDA, however, encourages these petitioners and all interested persons to comment on this proposal and on the other descriptor proposals published elsewhere in this issue of the Federal Register.

C. The 1990 Amendments

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101–535). Section 3(b)(1)(A) of the 1990 amendments requires that FDA issue regulations that define claims that characterize the level of nutrients that are of the type that are required to be declared in nutrition labeling. Specifically, FDA was directed to promulgate regulations prescribing the use of the terms "free," "low," "light" or "lite," "reduced," "less," and "high" to characterize the level of these nutrients, unless the Secretary finds that the use of any such term would be misleading (section 3(b)(1)(A)(iii) of the 1990 amendments). Regulations prescribing general requirements for the use of nutrient content claims and defining specific descriptors are proposed in other documents published elsewhere in this issue of the Federal Register. Section 3(b)(1)(A)(viii) of the 1990 amendments authorizes FDA to issue regulations to permit the use of nutrient content claims for butter.

The legislative history of the 1990 amendments, specifically the House of Representatives Report 101–538, 101st Cong., 2d sess. 22–23 (June 13, 1990), states that while the Committee on Energy and Commerce believed that FDA has authority under current law to permit nutrient content claims on butter products, the 1990 amendments "explicitly [permit] the Secretary to allow a claim described in section 403(r)(1)(A) of the act (such as 'light') to be made for butter." The House Report goes on to state that "[i]n issuing regulations for claims concerning fat, calories, and other nutrients in butter, the Secretary should consider arguments concerning the appropriate characteristics of butter." (*Id.*, at 23.) This proposal gives interested persons the opportunity to present their views on this issue.

II. The Proposal

A. Tentative Finding that Providing for the Use of Nutrient Content Claims for Butter Will Assist Consumers in Maintaining Healthy Dietary Practices

FDA believes that the use of nutrient content claims for butter will assist consumers in maintaining healthy dietary practices. "The Surgeon General's Report on Nutrition and Health" (Ref. 1) emphasizes the need for most people to reduce their consumption of fat, saturated fat, and cholesterol and to achieve and maintain a desirable body weight. It states that heart disease, cancer, and stroke are the three leading causes of death in the United States, and that diet plays a part in the development of these conditions as well as other chronic health problems, such as atherosclerosis, high blood pressure, diabetes mellitus, obesity, osteoporosis, dental diseases, and diverticular disease. A product that has been modified to have significantly lower levels of fat, saturated fat, sodium, or cholesterol so that it can bear nutrient content claims will, therefore, be of nutritional benefit to consumers.

FDA notes that there is consumer demand to purchase modified dairy products. Under 21 CFR 130.17, FDA has issued temporary marketing permits for light sour cream, light ice cream, nonfat cottage cheese, and light eggnog. FDA has also granted temporary marketing permit extensions for light sour cream and light eggnog. The manufacturers submitting the applications for the extensions included information gathered under their market tests that shows a high level of consumer acceptance of those products.

B. FDA's Traditional View of How Modified Butter Products Must Be Labeled and the Effect of the 1990 Amendments

Congress provided the definition for "butter" in section 201a of the act to protect consumers from butter-like products that were inferior to the butter that they expected to purchase. Consistent with this, one of the main purposes of the act is to protect consumers from economic deception. A product using the term "butter" must comply with the statutory definition of butter, or its labeling would be false, and it would be misbranded under section 403(a)(1) of the act (21 U.S.C. 343(a)(1)). A food sold under the name "butter" that does not comply with the statutory standard for butter also is in violation of section 403(b) of the act (21 U.S.C. 343(b)) in that it is sold under the name of another food. These provisions apply to all foods defined by a standard of identity.

Therefore, a food whose statement of identity includes a term that is defined by a food standard purports to be that standardized food and must comply with the applicable standard. The effect of this requirement, however, is that a product labeled as, for example, "light butter" because it contains less fat and calories than regular butter, or a product labeled as "light sour cream" because it contains less fat and calories than regular sour cream, would be misbranded because it does not meet the applicable standard.

The maker of the "light sour cream" product has had an alternative, however. It has been able to submit a petition for a new food standard that will define "light sour cream" as a different product than "sour cream." Moreover, it could obtain a temporary marketing permit, as several manufacturers have, that will allow it to market the product while it develops its petition, and the petition is reviewed by FDA.

The maker of the "light butter" product, however, has had no such option. As stated above, section 401 of the act prohibits FDA from establishing any new standards for foods that purport to be butter.

Consequently, modified butter products have been sold under a common or usual name such as "dairy spread," along with appropriate labeling that accurately informs the consumer as to what the product is but that does not represent it to be butter. Modified butter products that are nutritionally inferior (as defined in § 101.3(e) (21 CFR 101.3(e))) to butter are sold as "imitation butter."

To provide some relief in this situation, Congress passed section 3(b)(1)(A)(viii) of the 1990 amendments. While this section does not directly address the prohibition in section 401 of the act, it clearly evidences an intent by

Congress to permit nutrient content claims like "light" to be made for butter. This provision was discussed by Congressman Torricelli and Congressman Waxman, a sponsor of the bill that became the 1990 amendments.

Mr. Torricelli * * *

My inquiry is whether it would be within the authority of the FDA under the language we have been discussing to authorize the marketing of a product called lite butter that achieved * * * 35 to 40 percent milkfat, and with a third less calories as long as it were not nutritionally inferior and kept other characteristics of butter and were properly labeled * * *.

Mr. Waxman * * *

[I]t would be in the FDA's discretion to determine the characteristics of light butter. (Congressional Record, H5845, July 30, 1990.)

It is FDA's job to read section 3(b)(1)(A)(viii) of the 1990 amendments and section 401 of the act together and to develop an interpretation that gives effect to both provisions. Thus, proposed § 101.67 focuses not on the ingredients that may be used in a butter product, as a standard would, but rather, as section 3(b)(1)(A)(viii) of the 1990 amendments does, on the circumstances in which nutrient content claims may be used. While the proposed regulation, in § 101.67(a)(2), does list the ingredients of the food, this list is essentially the same as that in section 201a of the act, with two small additions that reflect Congress's intent in passing the 1990 amendments and that do not represent a change from the statutory standard. FDA believes that its proposed approach harmonizes section 3(b)(1)(A)(viii) of the 1990 amendments and section 401 of the act. The agency requests comments on its approach.

C. FDA's Proposed Regulation

In response to section (3)(b)(1)(a)(viii) of the 1990 amendments, FDA is proposing to permit nutrient content claims to be made for butter. Under proposed § 101.67(a), such claims may be made if the product meets the applicable definition of the nutrient content claims, it complies with certain content requirements that assure that it can fairly be characterized as "butter," and it is not nutritionally inferior to butter as butter would be produced under section 201a of the act. In addition, FDA is proposing to require that the product that bears the nutrient content claims have similar performance characteristics to butter, and that to the extent it does not, this fact is disclosed with appropriate prominence in the labeling. Each of these proposed requirements is discussed in more detail below.

1. The Nutrient Content Claim

Proposed § 101.67(a)(1) provides that a butter product may bear a nutrient content claim if it complies with both the general requirements for nutrient content claims in § 101.13 and the requirements for use of the particular nutrient content claim that is to be applied to the product.

Section 101.13, as proposed elsewhere in this issue of the **Federal Register**, prescribes the circumstances in which claims that characterize the level of a nutrient in a food may be made on a food label or in labeling. Proposed § 101.13(b) limits the claims that can be used to expressly or by implication characterize the level of a nutrient (nutrient content claim) of the type required to be declared in nutrition labeling pursuant to § 101.9 to those that have been defined by FDA by regulation.

To prevent consumer deception as a result of a manufacturer reducing the serving size and, thereby, the milkfat content per serving, FDA is proposing that the serving size for butter that is to bear a nutrient content claim must be the same as that established for regular butter. (See proposed § 101.12(g).) On July 19, 1990 (55 FR 29517), FDA published a proposal to establish serving sizes for 159 food product categories and proposed the standard serving size for butter and modified versions of butter as 1 tablespoon. FDA is retaining these amounts in its reproposal of its serving size regulations published elsewhere in this issue of the **Federal Register** as part of its food labeling initiative to implement the provisions of the 1990 amendments.

The agency is defining in proposals published elsewhere in this issue of the **Federal Register** the terms "free,. "low," "light" or "lite," "reduced," and "high." In addition, FDA is proposing to define the terms "very low" (for sodium only) and "source" and to make provision for the use of comparative statements using the terms "less," "fewer," and "more" because the agency has tentatively concluded that they would be useful in helping consumers choose a healthy diet.

For example, under proposed § 101.62 concerning fat claims, which is published elsewhere in this issue of the **Federal Register**, a product must be formulated to have a significant reduction in fat content (50 percent) to bear a "reduced fat" descriptor. A product that contains only slightly less (e.g., 10 percent) fat than the regular version of the product could not bear such a claim.

To avoid consumer confusion, FDA believes that the principal display panel of the label should clearly state the difference between butter as defined in section 201a of the act and the product that bears the nutrient content claim. Thus, in proposed § 101.67(a)(1), FDA is requiring, in accordance with proposed §§ 101.13 and 101.62(b)(4)(ii), that for example, if a .reduced fat" claim is made, a truthful comparative statement must appear in immediate proximity to the most prominent use of the claim (e.g., the statement of identity). The comparative statement would disclose the percentage difference between the level of milkfat in the product that bears the claim and 80 percent milkfat, which is the level specified for butter in section 201a of the act and which FDA is proposing, in § 101.67(a)(1), to use as the basis for calculating milkfat reductions. Proposed § 101.62 also requires that the comparative statement include quantitative information comparing the actual amount of fat in a serving of the butter for which the claim is made to the amount in regular butter. For example, a product that contains 40 percent milkfat could be labeled "reduced fat butter" and bear, in immediate proximity to the name, the statement: .Contains 50 percent less fat than regular butter. Fat content has been reduced from 12 grams to 6 grams per serving."

FDA advises that under proposed § 101.62(d)(4), which defines cholesterol claims, reducing the cholesterol content of butter will not justify a reduced cholesterol claim because of the high saturated fat content of butter. Comments on the impact of cholesterol claim restrictions on butter labeling should be directed to docket numbers 84N–0153 and 90N–0256 pertaining to the proposed descriptor regulations for fats and cholesterol published elsewhere in this issue of the **Federal Register**.

As provided in the statutory standard, salt is an optional ingredient in butter. Thus, under proposed § 101.67, sodium and salt content nutrient content claims that are truthful and in accordance with proposed §§ 101.13 and 101.61 may also be used for butter.

2. "Butter"

As a condition for the use of a nutrient content claim on butter, the product that is to bear the nutrient content claim must not only satisfy the requirements for the claim, it must also be fairly described as "butter." The characterizing component of butter is milkfat. Under section 201a of the act, "butter" must contain at least 80 percent milkfat.

The legislative history of the 1990 amendments makes clear, however, that Congress intended to authorize FDA to permit the use of nutrient content claims on butter products that contain less than 80 percent fat. (H. Rept. 101–538, 101st Cong., 2d sess. 23.) As stated above, in floor debate preceding passage of the 1990 amendments in the House, a Congressman asked one of the sponsors of the bill whether it would permit FDA to allow a product that contains 35 or 40 percent milkfat to be called "lite butter." The response was that it would. (Congressional Record H5844, July 30, 1990).

Therefore, in § 101.67(a)(2), FDA is proposing to permit the use of the term "butter" in conjunction with a nutrient content claim if the product that bears the nutrient content claim is made from the ingredients and constituents of the ingredients listed in section 201a of the act, but the agency is not proposing to require that the product contain a particular level of milkfat. FDA believes that this proposed action is consistent with congressional intent.

In the House Report, Congress directed FDA to consider arguments concerning the appropriate characteristics of butter. In a footnote, the Report continued:

> The Committee is aware that the dairy industry takes the position that products containing less than approximately 50 percent milkfat lose some of the characteristics of butter. In connection with the promulgation of the regulations, representatives of dairy interests and health experts will have the opportunity to present their views on the issue to the Secretary. (H. Rept. 101–538, 101st Cong., 2d sess. 23. n. 3.)

FDA requests comments on whether its tentative decision not to include a minimum milkfat level in § 101.67 is appropriate.

FDA is proposing to add two types of ingredients to the list of ingredients that derives from section 201a of the act. First, to ensure that a butter product that bears a nutrient content claim is not nutritionally inferior to butter that is produced under section 201a of the act, FDA is proposing to permit the addition of nutrients to the product. The legislative history makes clear that Congress anticipated that a butter product that bears a nutrient content claim would not be nutritionally inferior to butter. (Congressional Record H5845, July 30, 1990.)

Secondly, FDA is proposing to permit the use of safe and suitable bacterial cultures. The agency is doing so for two reasons. First, butter has historically been a cultured product. When the Act of August 2, 1886 was passed, milk and cream used in the manufacture of butter were permitted to sour spontaneously or by the addition of a starter of soured milk or cream prior to churning (Ref. 2). Thus, FDA is merely conforming proposed § 101.67 to the way that butter has traditionally been produced. Secondly, in the floor debate that preceded the House passage of the 1990 amendments, a sponsor of the bill in the House agreed that under the language of the bill, it would be within the FDA s authority to grant the Johanna Farms, Inc., petition. (Congressional Record H5844.) The petition specifically provides for the use of safe and suitable bacterial cultures.

FDA realizes that manufacturers may want to use ingredients that are not listed in § 101.67(a)(2) to yield an acceptable "butter" product. Therefore, FDA is requesting comment on whether it should provide for the use of safe and suitable nondairy ingredients to improve texture, prevent syneresis, add flavor, or extend the shelf life in § 101.67(a)(2). FDA is also requesting comment concerning the addition of water instead of skim milk, whey, or milk, as an ingredient in butter products to replace the milkfat. If comments support the use of safe and suitable nondairy ingredients and provide a substantial basis for their use, FDA may provide for the use of these ingredients in any final rule based on this proposal.

Under proposed § 101.67(c), each of the ingredients that is used in the butter for which a claim is made must be declared on the label as required by the applicable sections of 21 CFR part 101. According to § 101.4, all ingredients must be listed by common or usual name in descending order of predominance by weight on either the principal display panel or the information panel.

3. Nutritional Inferiority

FDA is proposing to specifically require in § 101.67(a)(3) that a product that bears a nutrient content claim not be nutritionally inferior to standardized butter. A modified butter product that is nutritionally inferior to butter would be an imitation food under § 101.3(e)(1) and thus subject to the requirements of section 403(c) of the act. In § 101.3(e)(4)(i), FDA defines nutritional inferiority as any reduction in the content of an essential nutrient that is present in the food imitated in a measurable amount. In § 101.3(e)(4)(ii), FDA has defined a measurable amount of an essential nutrient in a food as 2 percent or more of the U.S. Recommended Daily Allowance (U.S. RDA) of protein or any vitamin or mineral listed under current § 101.9(c)(7)(iv) per average or usual serving or, where the food is customarily not consumed directly, per average or usual portion, as established in § 101.9. FDA is proposing in the document on mandatory nutrition labeling published elsewhere in this issue of the **Federal Register** to establish Reference Daily Intakes (RDI's) for use in declaring nutrient content in nutrition labeling and to replace the current U.S. RDA's with the RDI's. If FDA adopts that proposal, nutritional equivalence will be based on the established RDI.

Butter is a significant source (as defined in current § 101.9(c)(7)(v)) of fat soluble vitamins such as vitamin A. A 1-tablespoon serving of butter provides 10 percent of the U.S. RDA for vitamin A. Any reduction in the amount of milkfat also reduces the amount of vitamin A and other fat soluble vitamins per serving. Therefore, FDA believes that vitamin A and other essential nutrients must be added to restore nutrients to products using the term "butter" in their name. Given Congress's intent to provide for butter products with modified milkfat levels (Congressional Record H5844, July 30, 1990), FDA believes it is appropriate to provide for the addition of such nutrients, even though the statutory standard for butter does not provide for the addition of those ingredients.

4. Performance Characteristics

FDA believes that consumers expect that a product bearing the term "butter" will resemble butter and perform like butter. Therefore, in order to not mislead consumers, FDA believes that a product bearing the term "butter" in its identity statement should meet these expectations. The relevant performance characteristics include physical properties (e.g., melting point), organoleptic characteristics (e.g., texture, aroma, and taste), functional properties (e.g., spreadability), and shelf life.

FDA recognizes, however, that it may not be possible or practical to produce a product that meets the requirements for a fat claim and that performs similarly to butter in all respects. Therefore, to assure that consumers are not misled as to the characteristics of the product, FDA is proposing in § 101.67(b) to require that the label include a statement informing the consumer of any significant differences in performance characteristics between a product that bears a nutrient content claim and standardized butter.

For example, reduced fat butter may not perform the same as standardized butter when used as an ingredient in

baked goods, and if this proposal is adopted, a statement such as "not recommended for baking purposes" will have to appear on the label of the former product. Under 403(f) of the act, FDA believes that the statement must appear on the label with such conspicuousness and in such terms as to render it likely to be read and understood by the consumer under customary conditions of purchase and use. FDA believes that the statement must appear in the same area of the label as the statement of identity for the product so that the consumer will know where to find such information. Therefore, FDA is proposing in § 101.67(b) to require that this statement appear on the principal display panel within the bottom 30 percent of the area of the label panel with appropriate prominence, that is, it shall be in type no less than one half the size of the type of the most prominent nutrient claim on the panel but no smaller than one-sixteenth of an inch.

The agency tentatively concludes that this information about the performance characteristics of the product is a material fact under section 201(n) of the act because it bears on the consequence of the use of the article. Accordingly, this information must be communicated to the consumer on the product label, or the labeling would be misleading, and the product would be misbranded under section 403(a) of the act. FDA is requesting comments concerning what performance characteristics butter that bears a claim may possess and still be considered to perform like standardized butter.

D. Conclusion

FDA believes that descriptors should be used to make available to the consumer informatively labeled products and to aid the consumer by providing a larger variety of products to meet nutritional goals. FDA is issuing this proposal in furtherance of these objectives as well as to implement section 3(b)(1)(A)(viii) of the 1990 amendments and to respond to the Johanna Farms, Inc., petition. FDA requests comments on the appropriateness of its approach and on alternative approaches that are more appropriate to attain these objectives.

III. Economic Impact

FDA has examined the economic implications of the proposed rule pertaining to 21 CFR Part 101 requirements as required by Executive Order 12291 and the Regulatory Flexibility Act. Executive Order 12291 compels agencies to use cost-benefit analysis as a component of decisionmaking and the Regulatory Flexibility Act requires regulatory relief for small businesses where feasible.

FDA is proposing changes to the food label that will, for the most part, codify changes mandated by the 1990 amendments. The agency has prepared a regulatory impact analysis (RIA) to determine the economic effects of this and other proposed labeling rules which amend food labeling regulations under 21 CFR part 101. This proposed action will provide consumers with a selection of butter products that are informatively labeled.

Because there are no additional costs to manufacturers to comply with this proposed regulation, FDA concludes that this is not a major rule as defined by Executive Order 12291. In addition, FDA certifies that this action will not result in a significant economic impact on a substantial number of small entities as defined by the Regulatory Flexibility Act.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

In accordance with section 3(b)(1)(B) of the 1990 amendments, FDA must issue by November 8, 1992, final regulations permitting nutrient content claims for butter. If the agency does not promulgate final regulations by November 8, 1992, section 3(b)(2) of the 1990 amendments provides that the regulations proposed in this document shall be considered as the final regulations. The agency has determined that 90 days is the maximum time that it can provide for the submission of comments and still meet this statutory timeframe for the issuance of final regulations. Thus, the agency is advising that it will not consider any requests under 21 CFR 10.40(b) for extension of the comment period beyond February 25, 1992. The agency must limit the comment period to no more than 90 days to assure sufficient time to develop a final rule based on this proposal and the comments it receives.

VI. References

The following information has been placed on display in the Dockets Management Branch (address above), and may be seen by interested persons between 9 a.m. and 4 p.m. Monday through Friday.

2. U.S. Department of Justice opinion letter, from Harris M. Daugherty, U.S. Attorney General to the U.S. Secretary of the Treasury Department, August 12, 1921.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.67 is added to Subpart D to read as follows:

§ 101.67 Use of nutrient content claims for butter.

(a) Claims may be made to characterize the level of nutrients, including fat, in butter if:

(1) The claim complies with the requirements of § 101.13 and with the requirements of the regulations in this part that define the particular nutrient content claim that is used and how it is to be presented. In determining whether a claim is appropriate, the calculation of the percent fat reduction in milkfat shall be based on the 80 percent milkfat requirement provided by the statutory standard for butter (21 U.S.C. 321a);

(2) The product contains cream or milk, including milk constituents (including, but not limited to, whey, casein, modified whey, and salts of casein), or both, with or without added salt, with or without safe and suitable colorings, with or without nutrients

added to comply with paragraph (a)(3) of this section, and with or without safe and suitable bacterial cultures; and

(3) The product is not nutritionally inferior, as defined in § 101.3(e)(4), to butter as produced under 21 U.S.C. 321a.

(b) The performance characteristics (e.g., physical properties, organoleptic characteristics, functional properties, shelf life) of the product shall be similar to butter as produced under 21 U.S.C. 321a. If there is a significant difference in performance characteristics, the label shall include a statement informing the consumer of such difference (e.g., if appropriate, "not recommended for baking purposes"). Such statement shall appear on the principal display panel within the bottom 30 percent of the area of the label panel in type that shall be no less than ½ the size of the type used for such claim but no smaller than 1/16 of an inch.

(c) Each of the ingredients used in the food shall be declared on the label as required by the applicable sections of this part.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

21 CFR Part 100

[Docket No. 91N-0038]

RIN 0905-AD08

State Petitions Requesting Exemption From Federal Preemption

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to provide for petitions requesting exemption from preemption for certain State or local food standards and other labeling requirements that are preempted under the provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). The proposed regulations set out the procedures for the submission, and for agency review, of these petitions, and the information that the petitioner should supply. Petitions by State and local governments seeking exemption from specified preemptive Federal requirements are specifically authorized by the 1990 amendments.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective November 8, 1992, or 30 days after date of publication in the **Federal Register**, if earlier.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857, 301-443-1751.

FOR FURTHER INFORMATION CONTACT: Elizabeth J. Campbell, Center for Food Safety and Applied Nutrition (HFF-312), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-485-0229.

SUPPLEMENTARY INFORMATION:

I. Background

A. Federal Labeling Requirements Made Preemptive by the Nutrition Labeling and Education Act of 1990

The Nutrition Labeling and Education Act of 1990 (Pub. L. 101-535) (the 1990 amendments) amends the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321 *et seq.*) (the act) to provide, among other things, for Federal preemption of certain food standards and labeling requirements issued by a State or a political subdivision of a State (hereinafter referred to collectively as "State"). Section 6(a) of the 1990 amendments adds section 403A to the act (21 U.S.C. 343-1) which provides that after the effective date of the operative provisions (prescribed in section 10(b) of the 1990 amendments), no State may directly or indirectly establish under any authority, or continue in effect as to any food in interstate commerce, any of the following types of requirements:

1. Any requirement for a food that is the subject of a standard of identity established under section 401 of the act (21 U.S.C. 341) that is not identical to such standard of identity or that is not identical to the requirements of section 403(g) of the act (21 U.S.C. 343(g)). Section 403(g) of the act states that a food is misbranded if it purports to be or is represented as a food for which a definition and standard of identity has been established under section 401 of the act, unless it conforms to the definition and standard, and its label bears the name of the food specified in the definition and standard. Preemption of this type of requirement became effective on November 8, 1990, the date of enactment of the 1990 amendments (section 10(b)(1)(A) of the 1990 amendments).

2. Any requirement for the labeling of foods that relates to use of the term "imitation" that is not identical to the requirements of section 403(c) of the act; any requirement for label information identifying the manufacturer, packer, or distributor and the quantity of contents, that is not identical to the requirements of section 403(e) of the act; and any requirement concerning the listing on the label of ingredients that is not identical to the requirements of section 403(i)(2) of the act. Preemption of these types of requirements (section 403A(a)(2) of the act) will take effect on November 8, 1991, 1 year after the date of the enactment of the 1990 amendments (section 10(b)(1)(B) of the 1990 amendments).

3. Any requirement for the labeling of food that is offered for sale under the name of another food that is not identical to the requirements of section 403(b) of the act; any requirement concerning a container that is so made, formed, or filled as to be misleading that is not identical to the requirements of section 403(d) of the act; any requirement concerning the prominence of required information on the label that is not identical to the requirements of section 403(f) of the act; any requirement concerning the labeling of a food purporting to be or represented as a food for which a standard of quality or a standard of fill has been established under section 401 of the act that is not identical to the requirement of section 403(h) of the act; any requirement that the label of a food bear the common or usual name of the food that is not identical to the requirements of section 403(i)(1) of the act; and any requirement that the label states whether a food contains any artificial flavoring, artificial coloring, or a chemical preservative that is not identical to the requirements of section 403(k) of the act. Under section 6(b) of the 1990 amendments, these six provisions (section 403A(a)(3) of the act) do not become preemptive until FDA determines that each is being adequately implemented by Federal regulations (see section 403(A)(a) of the act and section 10(b)(1)(C) of 1990 amendments).

Whether there is adequate implementation of the State and Federal requirements of the type addressed in section 403A(a)(3) of the act is being studied by the Committee on State Food Labeling of the National Academy of Sciences (the committee), Institute of Medicine, Food and Nutrition Board (56 FR 21388, May 8, 1991 (and 56 FR 55130, October 24, 1991)). Although the 1990 amendments state that the contract shall provide for completion of the committee's study by May 8, 1991, completion of the study and the committee's report has been delayed by unforeseen circumstances (56 FR 21388,

May 8, 1991 and 56 FR 55130, October 24, 1991). The committee has informed the agency that the study report will take more time than initially anticipated because of the magnitude of the undertaking and its importance, as well as the complexity of the issues involved.

The agency believes that the committee's report is crucial to the agency's development of a proposed list of which of the six provisions listed in section 403A(a)(3) of the act are being adequately implemented and which are not. Thus, a delay in publication of a proposed list beyond the August 8, 1991 date specified in the 1990 amendments is justified. The agency still expects to issue its final list of the sections of the act that are, and that are not, being adequately implemented by the November 8, 1992 deadline set in the 1990 amendments. If the agency does not issue a final list, the proposed list, which FDA expects to publish in early 1992, is to be considered the final list, and preemption will become effective on November 8, 1992 for those sections found to be adequately implemented in the proposed list.

Under the amendments, FDA is to also propose revisions by November 8, 1992, and issue final revisions by May 8, 1993, to any regulations found to be inadequately implemented (sec. 6(b)(3) of the 1990 amendments). Preemption will become effective on the effective date of the final revisions to any regulations initially found to be inadequate. If the agency does not issue final revisions by May 8, 1993, the proposed revisions will be considered the final revisions under the 1990 amendments, and preemption will become effective on May 8, 1993.

4. Any requirement for nutrition labeling or for nutrient content or health claims on food labels that is not identical to the requirements of section 403 (q) and (r) of the act. The 1990 amendments amended section 403 of the act by adding paragraphs (q) and (r) pertaining to nutrition labeling and label claims (nutrient content and health claims), respectively. Preemption of nutrition labeling requirements and requirements for label claims (section 403A (a)(4) and (a)(5) of the act) will become effective when regulations to implement sections 403 (q) and (r) of the act take effect (section 10 (b)(1)(D) and (b)(1)(E) of the 1990 amendments).

However, section 10(b)(2) of the 1990 amendments creates an exception to the effective dates for preemption granted under section 403A (a)(3), (a)(4), and (a)(5) of the act. Under this exception, if a State submits a petition for exemption from Federal preemption under section 403A(b) of the act within 18 months of enactment, i.e., by May 8, 1992, the State requirement will not be preempted until 24 months after the date of enactment of the 1990 amendments (November 8, 1992), or until FDA acts on the petition, whichever is later.

B. State Petitions for Exemption From Federal Preemption

The 1990 amendments also add section 403A(b) of the act, which permits the States to petition FDA for an exemption from the Federal preemption granted by section 403A(a) of the act. Three criteria must be met for an exemption to be granted. The State must show through the petition that the State requirement: (1) Would not cause any food to be in violation of any applicable requirement under Federal law, (2) would not unduly burden interstate commerce, and (3) addresses a particular need for information not met by the requirements of Federal law.

In the **Federal Register** of March 14, 1991 (56 FR 10906), the agency announced that it was developing procedural regulations to govern the content, substance, and agency review of State petitions in addition to the other types of petitions (petitions for health claims and nutrient content claims) specifically authorized by the 1990 amendments. In the March 14, 1991 notice, the agency stated its belief that the issuance of procedural regulations is a necessary first step in providing the framework within which a petitioner can develop the petitions authorized by the 1990 amendments, and within which the agency can evaluate and act on such petitions. In the same notice, the agency also advised that it will deny or defer action on any petition requesting action under the 1990 amendments that is submitted before issuance of final procedural regulations for petitions. However, as noted above, the 1990 amendments give special standing to States that submit petitions by May 8, 1992, seeking exemption from the preemption provisions of section 403A(a)(3), (a)(4), and (a)(5) of the act (section 10(b)(2) of the 1990 amendments). It would, therefore, be improper to deny such petitions because procedural regulations for State petitions have not been issued. The agency thus stated in the March 14, 1991 notice that it is likely to defer action on, rather than to deny, State petitions given this special standing until after this proposed rule is finalized. The agency requested information and comments from interested persons on the March 14, 1991 notice. The agency is reflecting section 10(b)(2) of the 1990 amendments in proposed § 100.1(g).

C. Comments to Agency Notice on Procedural Regulations

Twelve comments were received from States, industry, industry trade associations, and consumer interest groups in response to the March 14, 1991 notice. The comments were considered, and many of the recommendations were incorporated, or otherwise used, in the development of this proposed rule.

One comment requested that FDA withdraw the March 14, 1991 notice and not develop procedural regulations for petitions authorized by the 1990 amendments. The comment characterized the development of procedural regulations as a waste of agency resources, and stated that the development of regulations could take years to complete.

The agency disagrees with this comment. The 1990 amendments contemplate that the agency may issue regulations prescribing the conditions under which a State requirement may be exempt from Federal preemption. Section 403A(b) of the act specifically authorizes the agency to grant such exemptions from preemption "under such conditions as may be prescribed by regulation." Furthermore, the agency believes that it is essential that a State provide the agency with the necessary information to facilitate the agency's review of these petitions and to enable it to make the findings required by section 403A(b) of the act. The agency believes that the development of procedural regulations that specify the format of State petitions and the information that should be included in such petitions: (1) Will result in the most efficient use of the agency's and the States resources, (2) will expedite the review and the decision-making process, and (3) will enable the agency to evaluate all petitions in a consistent manner.

Some comments recommended that petitions for exemption from preemption be submitted as citizens' petitions under § 10.30 (21 CFR 10.30).

The agency believes that § 10.30 alone does not provide adequate guidance to a State seeking exemption from preemption, especially with respect to the specific showings required of a petitioner by the 1990 amendments. However, some of the provisions of § 10.30 are applicable to State petitions and have been adopted in the proposed procedural regulation as described in the next section.

Other comments recommended that the petition procedure be modeled after the Consumer Product Safety Commission's (CPSC) regulations for the

exemption of State requirements from preemption by the provisions of the Flammable Fabrics Act (15 U.S.C. 1191 *et seq.*), the Consumer Product Safety Act (15 U.S.C. 2051 *et seq.*), the Federal Hazardous Substances Act (15 U.S.C. 1261 *et seq.*), and the Poison Prevention Packaging Act (15 U.S.C. 1471 *et seq.*) (56 FR 3414, January 30, 1991). As is the case for the 1990 amendments, the preemption provisions of the four CPSC administered acts expressly bar differing State requirements unless exemption is granted by the Federal agency upon petition by a State.

An exemption may be granted by the CPSC only if it finds that compliance with the State requirement will not result in a violation of the applicable CPSC requirements; that the State requirement provides a substantially higher degree of protection than the CPSC requirement from the risk of illness or injury that they both address; and that the State requirement does not unduly burden interstate commerce. In 1977, the United States District Court for the District of Minnesota in *Cosmetic, Toiletry and Fragrance Association, Inc., et al.* v. *State of Minnesota et al.*, 440 F. Supp. 1216 (D. Minn. 1977), *affirmed* 575 F.2d 1256 (8th Cir. 1978), in examining the preemption provisions of the CPSC administered acts, described this approach as representing "the most appropriate response to the factors present in the modern regulatory process—legislative rulemaking on a national scale, state attempts to provide a greater degree of protection, and corresponding burdens on interstate commerce. As it also represents the most recent Congressional response, the court suspects that it would probably be adopted if Congress were once again to legislate with regards to food, drug, and cosmetic products." The 1990 amendments are a more recent congressional response, and Congress did adopt similar criteria.

The recommendation that the CPSC regulations serve as a model for this proposed rule has merit because the CPSC regulations and this proposed rule pertain to the same matter-exemption from preemption. Further, the agency finds the general format of the CPSC regulations to be useful and appropriate as a general format for the procedural regulations that the agency is proposing herein. The agency has therefore followed the same general format in its proposed regulation as is in the CPSC regulations in 16 CFR part 1061. However, many of the substantive elements of FDA's regulation differ from those of the CPSC regulation inasmuch as they address the substantive requirements of 1990 amendments.

Some comments requested that individuals or parties other than States be accorded the right to petition for exemption.

The agency believes that only States have legal standing to petition for exemption. The agency's opinion is based on the wording in the 1990 amendments that, "Upon petition of a State or a political subdivision of a State, the agency may exempt * * *." Thus, Congress did not authorize petitions from other parties.

Two comments indicated to the agency that preemption is not well understood. These comments stated that a State should be able to petition for an exemption from preemption when the State has labeling requirements that are not addressed directly or indirectly by Federal law, or when the State requirement is not preempted by any Federal law, either explicitly or implicitly.

The agency is not taking any action in response to these comments. If a State requirement is not preempted by a Federal law, it simply makes no sense to provide a mechanism by which a State can seek exemption from preemption for that requirement. An exemption is an immunity from a requirement. If the requirement does not apply, that is, the State requirement is not subject to preemption, there is no need for a mechanism by which the immunity may be sought.

Moreover, section 6(c)(1) of the 1990 amendments clearly manifests Congress's intention that the 1990 amendments "shall not be construed to preempt any provision of State law, unless such provision is expressly preempted under section 403A of the Act." Section 403A of the act is only operative in matters where there is a Federal requirement applicable to the labeling addressed in the State requirement. If there is no applicable Federal requirement that has been given preemptive status by Congress, there is no competing claim of jurisdiction, and, therefore, no basis under the 1990 amendments for Federal preemption or grounds to justify the submission of a State petition for exemption. Therefore, FDA has no authority under the 1990 amendments to rule on State petitions for exemption where the 1990 amendments have not imposed such Federal requirements. Of course section 6(c)(3) of the 1990 amendments provides that the amendments shall not affect any preemption, expressed or implied, which arises under the Constitution or other provisions of Federal law or regulation.

Several examples of the types of State requirements that would not be subject to the preemption provisions of the 1990 amendments were given in the Congressional Record of July 30, 1990 (H5642). The examples included State laws pertaining to issues for which there is no national framework, such as open date labeling, unit price labeling, container deposit labeling, religious dietary labeling, and previously frozen labeling.

Comments from States and consumer interest groups advocated that the agency apply liberal criteria in establishing the types and degree of information necessary to sustain a State's burden of proof in a petition. Comments from the food industry advocated strict construction of the 1990 amendments, and thus a more exacting standard for information requirements for State petitions.

In construing the provisions for exemption from preemption, the agency is guided by the policy in Executive Order 12612 (E.O. 12612) of October 26, 1987 on federalism (52 FR 41685 at 41687, October 30, 1987) that preemption of State law shall be restricted to the minimum level necessary to achieve the objectives of the statute. A corollary of this policy is that exemption from preemption should be liberally granted to the extent that the statutory objectives are fulfilled. FDA will consider E.O. 12612 as part of its review of any petitions that it receives.

The agency therefore must determine what effect a grant of an exemption from preemption will have on the congressional objective of providing national uniformity for certain aspects of food labels and labeling. Congress noted that since the enactment of the act in 1938, major changes have taken place in the marketing of foods in the U.S. The last 50 years have seen a decline in the numbers of plants and companies that serve regional markets and an increase in the nationwide distribution and marketing of foods. As one of the Senate sponsors of the bill that became the 1990 amendments stated:

> Today, we have a single food supply. Therefore, we need a single, integrated, and coordinated system with an appropriate allocation of regulatory responsibility among the Federal, State, and local governments. And, we need this for a reason: We must have confidence in the safety of our national food supply; and we must have consumers who can make informed decisions so they can adopt sound dietary practices.

(Congressional Record, S16611, October 24, 1990.)

Congress included limited express preemption in the 1990 amendments

because, according to one of the managers of the bill in the House,

> * * * it was decided that the fairest way to expect the food industry to support a nutrition labeling bill, was to give them some types of preemption of burdensome State laws that interfered with their ability to do business in all 50 States. Therefore, the bill provides industry with uniformity of law in a number of important areas—such as standards of identity, imitation labeling, and ingredient labeling—that will permit them to conduct their business in an efficient and cost-effective manner.

(Congressional Record, H12954, October 26, 1990.)

Congress reserved to the States the option of putting into effect composition or labeling requirements that differ from, and are more stringent than, Federal requirements providing that the States can demonstrate that the statutory criteria for exemption from preemption are met. The agency has included in the proposed regulations set forth below the matters that it considers necessary for a State to address to justify an exemption. A more liberal and less exacting interpretation of the types and depth of information required to sustain a State's burden of proof in a petition would undermine the congressional objective of national uniformity in certain aspects of food labeling.

Several States suggested that an exemption be granted by an advisory opinion rather than by regulation.

Although the 1990 amendments do not require that the exemption be granted by regulation, the agency believes that exempting a State requirement from Federal preemption is a type of action that may significantly affect many parties, including industry and consumers, and as such, the agency is proposing that such exemption be granted by notice and comment rulemaking. The rulemaking process will provide interested parties with the opportunity to comment on a proposed regulation granting exemption. If the agency determines that exemption should be granted, codification of the exemption in the food labeling regulations will ensure that all of the relevant information concerning the exemption, including its scope and conditions, is readily accessible for examination by all affected parties.

II. Proposed Regulation

The proposed rule states in § 100.1(a) the scope and purpose of the procedural regulation and cites the statutory authority for the agency to act on State petitions requesting exemption from preemption. Proposed § 100.1(b) defines the terms used in the proposed regulation.

In proposed § 100.1(c), the regulation lists the prerequisites that must be met for the merits of the petition to be considered. The State requirement must have been enacted in its final form and must either be in effect or would be in effect but for the provisions of section 403A(a) of the act (proposed § 100.1(c)(1)).

Under proposed § 100.1(c)(2), the preemptive Federal regulation also must have the full force and effect of law. However, FDA is proposing that a petition seeking exemption from a Federal requirement that has been published as a final rule with a designated effective date may be submitted before the effective date of that final rule. Petitions seeking exemption from Federal requirements that are preemptive under sections 403A (a)(3) through (a)(5) of the act and that are submitted before May 8, 1992 will be considered timely even though the requirements for which exemption from preemption is requested may not actually be in effect on that date. This portion of proposed § 100.1(c)(2) reflects the special standing given these petitions under section 10(b)(2) of the 1990 amendments.

Proposed § 100.1(c)(3) requires that the petitioner must be an official of the State having authority to act for, or on behalf of, the State in applying for an exemption.

Proposed § 100.1(c)(4) reflects that a State requirement is subject to preemption under section 403A(a) of the act if it is not identical to the corresponding Federal requirement. In proposed § 100.1(c)(4), the agency advises that it interprets the term "not identical" to mean that the State imposes obligations or contains provisions that are not imposed by or contained in the applicable Federal law regulation, including a standard of identity, quality, or fill, or that differ from those imposed by or contained by the applicable Federal law or regulation. Therefore proposed § 100.1(c) defines "not identical" as follows:

> "Not identical" does not refer to the specific words in the requirement but instead means that the State requirement directly or indirectly imposes obligations or contains provisions concerning the composition or labeling of food, or concerning a food container, that: (1) Are not imposed by or contained in the applicable provision (including any implementing regulation) of section 401 or 403 of the act, or (2) differ from those specifically imposed by or contained in the applicable provision (including any implementing regulation) of section 401 or 403 of the Act.

The requirements for petitions under section 403A(b) of the act are proposed in the petition format requirements in § 100.1(d). The petitioner should identify and document the State requirement for which exemption is sought, identify the Federal requirement that is believed to preempt the State requirement, explain the rationale of the State requirement, and compare it to the Federal requirement. The petitioner should address with specificity the grounds for exemption from preemption stated in the 1990 amendments. In this regard, the State will be expected to show that the State requirement will not cause a food label to be in violation of any applicable requirement under Federal law. In a case where a State requirement would allow for the violation of any Federal requirement, the agency could not grant the petition. The State would be free, however, to submit a citizen petition to the agency under § 10.30 to amend the Federal requirement to the extent the agency could affect such an amendment by regulation. The State will also have to supply specific information on the effect that the granting of exemption will have on interstate commerce. This information will be used by the agency in reaching a finding as to whether granting the exemption will unduly burden interstate commerce. Finally, the petitioner should identify and discuss the particular information need that the State requirement is designed to meet that is not met by Federal law. In this context, any public health considerations will be relevant.

The proposal also states that the petition needs to include a claim for a categorical exclusion under 21 CFR 25.24 or an environmental assessment under 21 CFR 25.31. Finally, the proposal states that the petition should include the name and address of the person to be notified of the agency's action concerning the petition and a certification by the petitioner that to his best knowledge and belief, the petition includes all information and views on which it relies.

The proposed rule provides in § 100.1(e) that public disclosure of State petitions will be governed by the rules specified in § 10.20(j). Proposed § 100.1(f) details the procedures for the agency's consideration of State petitions. Section 100.1(f)(1) states that unless otherwise specified, all relevant provisions and requirements of 21 CFR Part 10—Administrative Practices and Procedures, Subpart B—General Administrative Procedures, are applicable to State petitions requesting exemption from Federal preemption under section 403A(b) of the act. Such provisions include the opportunity for an interested person to request

reconsideration of the agency's decision on a petition under § 10.33.

Proposed § 100.1(f)(2) provides that if a petition does not meet the prerequisite requirements of § 100.1(c), the agency will issue a letter to the petitioner denying the petition and stating in what respect the petition did not meet the prerequisite requirements. Proposed § 100.1(f)(3) states that if a petition appears to meet the prerequisite requirements in § 100.1(c), it will be filed by the Dockets Management Branch, stamped with the date of filing, and assigned a docket number to be used for all subsequent submissions relating to the petition. The filing of the petition is without prejudice concerning the agency's final action on the petition. Proposed § 100.1(f)(4) provides that any interested person may submit written comments on a filed petition as provided in § 10.30(d).

Proposed § 100.1(f)(5) provides that within 90 days of the date of filing, the agency will furnish a response to the petitioner. The response will either: (1) State that the agency has tentatively determined that the petition merits the granting of an exemption, and that FDA intends to publish in the **Federal Register** a proposal to grant the exemption through rulemaking, (2) deny the petition and state the reasons for such denial, or (3) provide a tentative response stating why the agency has been unable to reach a decision on the petition, e.g., because of other agency priorities or a need for additional information.

An exemption under this proposed regulation will be granted only to the petitioner State. Exemption from preemption is largely based on an evaluation of a unique situation within a State. Should a situation arise that is more national in scope, the agency would consider amending the Federal requirement because the action requested would be more universal than that envisioned by Congress in providing for exemption.

III. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above), written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

IV. Paperwork Reduction Act

In accordance with the Paperwork Reduction Act of 1980 (44 U.S.C. chapter 35), the provisions of § 100.1 *Petitions requesting exemption from preemption for State or local requirements* relating to submission of petitions to FDA will be submitted for approval to the Office of Management and Budget (OMB). These provisions will not be effective until FDA obtains OMB approval. FDA will give notice of OMB approval of these requirements in the **Federal Register** as part of any final rule that is based on this proposal.

V. Economic Impact and Federalism Implications

FDA has examined the economic implications of the proposed rule pertaining to 21 CFR part 100 requirements as required by Executive Order 12291 and the Regulatory Flexibility Act. Executive Order 12291 compels agencies to use cost-benefit analysis as a component of decisionmaking and the Regulatory Flexibility Act requires regulatory relief for small businesses where feasible. As discussed in section I.C. of this document, FDA has fully considered the effect of Executive Order 12612.

This proposed regulation codifies procedures to be followed by a State or local government in petitioning the agency for an exemption from preemption by Federal food standards and labeling regulations. FDA has no information as to the cost to a State to prepare and submit the required petition to the agency; however, the petition process has been structured to minimize the paperwork burden on the State. If, for example, the required paperwork costs $100 per State action to prepare, it would take over 1 million enforcement actions to cause this proposed requirement to become a major rule, an unlikely event. Thus, FDA concludes that this proposed rule is not a major rule as defined by Executive Order 12291. In addition, FDA certifies that this action will not result in a significant economic impact on a substantial number of small entities as defined by the Regulatory Flexibility Act.

VI. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(8) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VII. Effective Date

The agency intends to issue final regulations pertaining to the State enforcement provisions of the 1990 amendments by November 8, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective November 8, 1992, or 30 days after publication in the **Federal Register**, if earlier. The agency believes that November 8, 1992, is the appropriate effective date for these petition regulations because that is the date on which section 307 of the act becomes effective, under which States may bring enforcement actions in their own names in Federal courts for violations of Federal requirements having preemptive effect under the 1990 amendments. November 8, 1992, is also the date by which the agency is to have published final regulations implementing sections 403(q) and 403(r) (see sections 2(b) and 3(1)(B) of the 1990 amendments) as well as a list of sections adequately implementing the statutory requirements specified in section 403A(a)(3) (see section 6(b)(3)(B) of the 1990 amendments).

List of Subjects in 21 CFR Part 100

Administrative practice and procedure, Food labeling, Foods.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 100 be amended as follows:

PART 100—GENERAL

1. The authority citation for 21 CFR part 100 continues to read as follows:

Authority: Secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. A new subpart A consisting of § 100.1 is added to read as follows:

Subpart A—State and Local Requirements

§ 100.1 Petitions requesting exemption from preemption for State or local requirements.

(a) *Scope and purpose.* (1) This subpart applies to the submission and consideration of petitions under section 403A(b) of the Federal Food, Drug and Cosmetic Act (the act), by a State or a political subdivision of a State, requesting exemption of a State requirement from preemption under section 403A(a) of the act.

(2) Section 403A(b) of the act provides that where a State requirement has been preempted under section 403A(a) of the act, the State may petition the agency

for an exemption. The agency may grant the exemption if the agency finds that the State requirement will not cause any food to be in violation of any applicable requirement under Federal law, will not unduly burden interstate commerce, and is designed to address a particular need for information that is not met by the preemptive Federal requirement.

(b) *Definitions.* (1) *Act* means the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321 *et seq.*).

(2) *Agency* means the Food and Drug Administration.

(3) *Commissioner* means the Commissioner of Food and Drugs.

(4) *State* means a State as defined in section 201(a)(1) of the act (which includes a territory of the United States, the District of Columbia, and Puerto Rico) or any political subdivision of a State having authority to issue food standards and food labeling regulations having force of law.

(5) *State requirement* means any statute, standard, regulation, or other requirement that is issued by a State.

(c) *Prerequisites for petitions for exemption from preemption.* The Food and Drug Administration will consider a petition for exemption from preemption on its merits only if the petition demonstrates that:

(1) The State requirement was enacted or was issued as a final rule by an authorized official of the State and is in effect or would be in effect but for the provisions of section 403A of the act.

(2) The State requirement is subject to preemption under section 403A(a) of the act because of a statutory provision listed in that section or because of a Federal standard or other Federal regulation that is in effect, or that has been published as a final rule with a designated effective date, and that was issued under the authority of a statutory provision listed in that section. For the purposes of this subpart, all petitions seeking exemption from preemption under section 403A(a)(3) through (a)(5) of the act, if submitted before May 8, 1992, will be considered timely even though the applicable statutory provisions or regulations are not yet in effect.

(3) The petitioner is an official of a State having authority to act for, or on behalf of, the Government in applying for an exemption of State requirements from preemption.

(4) The State requirement is subject to preemption under section 403A(a) of the act because it is not identical to the requirement of the preemptive Federal statutory provision or regulation including a standard of identity, quantity, and fill. *Not identical* does not refer to the specific words in the requirement but instead means that the State requirement directly or indirectly imposes obligations or contains provisions concerning the composition or labeling of food, or concerning a food container, that:

(i) Are not imposed by or contained in the applicable provision (including any implementing regulation) of section 401 or 403 of the act; or

(ii) Differ from those specifically imposed by or contained in the applicable provision (including any implementing regulation) of section 401 or 403 of the act.

(d) *Form of Petition.* (1) All information included in the petition should meet the general requirements of § 10.20(c) of this chapter.

(2) Four copies of the petition for exemption from preemption for a State requirement shall be submitted to the Dockets Management Branch in the following form:

(Date)_____

Dockets Management Branch, Food and Drug Administration, Department of Health and Human Services, Rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857.

Petition Requesting Exemption From Preemption for State Requirement

The undersigned submits this petition under section 403A(b) of the Federal Food, Drug, and Cosmetic Act to request that the Food and Drug Administration exempt a State requirement from preemption.

The undersigned has authority to act for, or on behalf of, the (*identify State or political subdivision of the State*) because (*document petitioner's authority to submit petition on behalf of the State*).

A. Action Requested

1. Identify and give the exact wording of the State requirement and give date it was enacted or issued in final form.

2. Identify the specific standard or regulation that is believed to preempt the State requirement and the section and paragraph of the act that the standard or regulation implements.

B. Documentation of State Requirement

Provide a copy of the State requirement that is the subject of the application. Where available, the application should also include copies of any legislative history or background materials used in issuing the requirement, including hearing reports or studies concerning the development or consideration of the requirement.

C. Statement of Grounds

A petition for an exemption from preemption should contain the following:

1. An explanation of the State requirement and its rationale, and a comparison of State and Federal requirements to show differences.

2. An explanation of why compliance with the State requirement would not cause a food to be in violation of any applicable requirement under Federal law.

3. Information on the effect that granting the State petition will have on interstate commerce. The petition should contain information on economic feasibility, i.e., whether the State and Federal requirements have significantly different effects on the production and distribution of the food product; comparison of the costs of compliance as shown by data or information on the actual or anticipated effect of the State and Federal requirements on the sale and price of the food product in interstate commerce; and the effect of the State requirement on the availability of the food product to consumers. To the extent possible, the petition should include information showing that it is practical and feasible for producers of food products to comply with the State requirement. Such information may be submitted in the form of statements from affected persons indicating their ability to comply.

4. Identification of a particular need for information that the State requirement is designed to meet, which need is not met by Federal law. The petition should describe the conditions that require the State to petition for an exemption, the information need that the State requirement fulfills, the inadequacy of the Federal requirement in addressing this need, and the geographical area or political subdivision in which such need exists.

D. Environmental Impact

The petition shall contain a claim for categorical exclusion under 21 CFR 25.24 or an environmental assessment under 21 CFR 25.31.

E. Notification

Provide name and address of person, branch, department, or other instrumentality of the State government that should be notified of the Commissioner's action concerning the petition.

F. Certification

The undersigned certifies, that, to the best knowledge and belief of the undersigned, this petition includes all information and views on which the petition relies.

(Signature) _____
(Name of petitioner) _____
(Mailing address) _____
(Telephone number) _____

(e) *Submission of petition for exemption; public disclosure.* The availability for public disclosure of a petition for exemption will be governed by the rules specified in § 10.20(j) of this chapter.

(f) *Agency consideration of petitions.* (1) Unless otherwise specified in this section, all relevant provisions and requirements of subpart B of part 10 of this chapter, are applicable to State petitions requesting exemption from Federal preemption under section 403A(b) of the act.

(2) If a petition does not meet the prerequisite requirements of paragraph (c) of this section, the agency will issue a letter to the petitioner denying the

petition and stating in what respect the petition does not meet these requirements.

(3) If a petition appears to meet the prerequisite requirements in paragraph (c) of this section, it will be filed by the Dockets Management Branch, stamped with the date of filing, and assigned a docket number. The docket number identifies the file established by the Dockets Management Branch for all submissions relating to the petition, as provided in this part. Subsequent submissions relating to the matter must refer to the docket number and will be filed in the docket file. The Dockets Management Branch will promptly notify the petitioner in writing of the filing and docket number of a petition.

(4) Any interested person may submit written comments to the Dockets Management Branch on a filed petition as provided in § 10.30(d) of this chapter.

(5) Within 90 days of the date of filing the agency will furnish a response to the petitioner. The response will either:

(i) State that the agency has tentatively determined that the petition merits the granting of an exemption, and that it intends to publish in the **Federal Register** a proposal to grant the exemption through rulemaking;

(ii) Deny the petition and state the reasons for such denial; or

(iii) Provide a tentative response indicating why the agency has been unable to reach a decision on the petition, e.g., because of other agency priorities or a need for additional information.

(g) If a State submits a petition for exemption of a State requirement from preemption under section 403A(a)(3) through (a)(5) of the act before May 8, 1992, that State requirement will not be subject to preemption until:

(1) November 8, 1992; or

(2) Action on the petition, whichever occurs later.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

[Docket No. 91N-0343]

RIN 0905-AD08

State Enforcement Provisions of the Nutrition Labeling and Education Act of 1990

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to implement section 4 of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments), which provides for State enforcement of certain requirements of the Federal Food, Drug, and Cosmetic Act (the act), so long as the state provides 30 days notice of its intent to act and complies with other procedural requirements before taking any such enforcement action. The agency is proposing to adopt regulations that will provide the states with instructions on how to give the requisite 30-day notice. FDA has framed these instructions to ensure that this notification system functions efficiently. This proposal also describes relevant State and Federal obligations.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Janice F. Oliver, Center for Food Safety and Applied Nutrition (HFF-310), Food and Drug Administration, 200 C Street SW., Washington, DC 20204, 202-485-0187.

SUPPLEMENTARY INFORMATION:

I. Background

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101-535). The 1990 amendments make the most significant changes in food labeling law since the passage of the act in 1938. In this document, FDA is proposing to adopt procedures to implement section 4 of the 1990 amendments, which amended section 307 of the act (21 U.S.C. 337) to authorize states to enforce certain sections of the act in their own names.

Before the passage of the 1990 amendments, section 307 of the act required that all enforcement proceedings be by, and in the name of, the United States. A state could only use its own laws to bring enforcement action against food located in that state. Any enforcement of the act had to be undertaken by the Federal government.

Under the 1990 amendments, section 307(b)(1) of the act has been revised to authorize a state to bring in Federal court in its own name and within its jurisdiction proceedings for the civil enforcement, or to restrain violations, of section 401 (Definitions and Standards for Foods) and of the misbranding provisions of sections 403(b) (offered for sale under another name), 403(c) (imitation of another food), 403(d) (misleading containers), 403(e) (name and address of manufacturer and net weight), 403(f) (prominence of information on label), 403(g) (representation as to definition and standard of identity), 403(h) (representation as to standard of quality and fill of container), 403(i) (common or usual name and ingredient labeling of all fabricated food), 403(k) (artificial flavoring, artificial coloring, or chemical preservative), 403(q) (nutrition information), and 403(r) (claims) of the act (21 U.S.C. 341, 343(b) through (i), (k), (q), and (r)), if the food that is the subject of the proceeding is located within the state. This provision will enable the states to supplement FDA s enforcement capabilities. It is effective 24 months after date of enactment. See section 10(a)(1)(C) of the 1990 amendments.

Under section 307(b)(2) of the act, however, a state's ability to exercise this new authority to enforce Federal law is predicated on certain conditions:

(1) A proceeding may not be commenced unless the state has given notice to FDA that it intends to bring such proceeding; also, the state must wait 30 days after giving notice before instituting action.

(2) If after receiving such notice, FDA, within 30 days, commences an informal or formal enforcement action pertaining to the food in question, the state may not bring its proceeding until an additional 60 days have passed (90 days from the initial notice by the state).

(3) If FDA is diligently prosecuting a proceeding in court pertaining to such food, has settled such proceeding, or has settled the informal enforcement action or the formal enforcement action pertaining to such food, the state may not institute a proceeding. Section 307(b)(2) of the act, however, does permit a state to intervene as a matter of right in any court proceeding that has been brought by FDA.

Although the statute and legislative history are silent as to what is meant by "informal or formal enforcement action," FDA interprets "informal enforcement actions" to include warning letters, recalls, and detentions. It interprets "formal enforcement actions" to include seizures, injunctions, and prosecutions. Informal actions include those that FDA can take administratively, while formal actions

are those that require the initiation of a judicial proceeding.

FDA believes that for purposes of section 307(b)(2)(B) of the act, a criminal action would be a "formal enforcement action pertaining to the food," even though the criminal action is against a corporation or individual and not the food itself (as a seizure action is), so long as the food in question provides the factual basis, or part of the factual basis, for the criminal charge (e.g., the charge is for introducing misbranded food into interstate commerce, and the allegedly misbranded food is the product that is to be the subject of the State action). FDA also believes that it is appropriate to regard a criminal action in this way, even though section 307(b)(1) only authorizes the state to bring proceedings for the civil enforcement, or to restrain violations, of the specified sections of the act because criminal proceedings may have the effect of eliminating the alleged misbranding, which would be the purpose of the State proceedings. FDA requests comments on these matters.

FDA is incorporating its interpretation of "informal enforcement action" and "formal enforcement action" in proposed § 100.2(j).

FDA is proposing to adopt in 21 CFR 100.2 a set of regulations that reflect the requirements of section 307 of the act. Proposed § 100.2(a) incorporates and reflects the provisions of section 307(b)(1) of the act. Similarly, proposed § 100.2(b) incorporates the provisions of section 307(b)(2)(A), (b)(2)(B), and (b)(2)(C) of the act, and proposed § 100.2(c) incorporates the provisions of the last sentence of section 307(b)(2).

FDA is also proposing to adopt procedures that a state should follow in notifying the agency of its intention to institute an enforcement action. First, in § 100.2(d), FDA is proposing a standard format for the letter of notification. The agency is also delineating the information that should be submitted in this letter. The letter should include the name and address of the State agency, the name and address of the firm against which enforcement action is proposed (if applicable), the specific products covered by the notification, the type and size of each product container, the manufacturing code (if applicable), and the reason for and type of anticipated State enforcement action, including the section of the act violated. For example, the notification would state that the product is in violation of section 403(b) of the act in that it is a product that is sold under the name of another food. It would go on to state that the product is sold as 100 percent pure blackberry juice, whereas it is actually a combination of grape and blackberry juice with grape juice being the predominant ingredient. Finally, it would state that the anticipated action is seizure. This information will enable FDA to quickly review the proposed State action and to determine whether the agency is contemplating, or has undertaken, action against the food in question, or would undertake action in light of the facts brought to its attention by the State.

Under proposed § 100.2(e), the letter of notification should be signed by a state official authorized to institute the proposed action. Such a signature will ensure that the state actually intends to institute the action in question. Under proposed § 100.2(f), the letter should be sent to the Food and Drug Administration, Division of Regulatory Guidance (HFF–310), Center for Food Safety and Applied Nutrition, 200 C St. SW., Washington, DC 20204. It is necessary that FDA headquarters be notified so that it can determine whether an action against the food in question has been brought or is contemplated anywhere in the country. Because Congress used the word "pertain" in section 307 of the act, FDA believes that an agency action anywhere in the United States against the food in question would, under section 307(b)(2), bar a State action against the food in Federal court. The agency does not interpret the act to require that FDA action be against the food in the state that has submitted a notice. This view is consistent with section 304(a)(1) of the act, which limits the number of actions against a particular misbranding to one, except in limited circumstances not applicable in this context.

FDA is proposing in § 100.2(g) and (h) to set out the procedures that it will follow in responding to a State's notification. Under proposed § 100.2(g), FDA will notify the state of the date on which it received the letter of notification within 2 working days after date of receipt of such letter. This notification is necessary so that the state is aware of the date on which the time periods set by section 307 of the act begin to run.

Under proposed § 100.2(h), the Director, Division of Regulatory Guidance, Office of Compliance, Center for Food Safety and Applied Nutrition will, within 30 days of the date of notification, respond to the notification by advising:

(1) Whether FDA has commenced an informal or formal enforcement action pertaining to the food that is the subject of the notification; or

(2) Whether FDA is prosecuting a proceeding in court pertaining to such food, has settled such proceeding, or has settled informal or formal enforcement action pertaining to such food.

The agency believes that the proposed regulations will be beneficial to the states and to FDA because having these procedures firmly in place will expedite the agency review process, will ensure an orderly and timely response to the state, and will facilitate coordinated Federal/State enforcement action against violative products in the marketplace.

State notifications to FDA pursuant to section 307 of the act will contain information compiled for law enforcement purposes and may contain trade secret or confidential commercial or financial information. Accordingly, FDA is proposing in § 100.2(i) that information contained in these required notifications will be exempt from public disclosure to the same extent to which such information would be so exempt pursuant to 21 CFR 20.61, 20.64, and 20.88 of this chapter.

FDA notes that it does not believe section 4 of the 1990 amendments on State enforcement precludes a state from taking enforcement action under its own statute or regulations in State court. It is the opinion of the agency that State regulations that are identical to Federal regulations are not preempted by section 6 of the 1990 amendments. Under section 6(c)(1) of the 1990 amendments, a provision of State law is not preempted unless such provision is expressly preempted under section 403A of the act (21 U.S.C. 343–1). Each clause of section 403A(a) of the act expressly preempts only those State regulations that are "not identical" to Federal requirements of section 403A(a) of the act (21 U.S.C. 343–1(a)(1)-(a)(5)). Accordingly, State regulations that are identical to Federal requirements are not preempted. Thus, a state may initiate enforcement proceedings under its own statute or regulations in State court. However, to facilitate uniformity in enforcement, FDA encourages states to discuss their State-court enforcement activities with the local FDA district office. Continued close cooperation between FDA and State regulatory agencies will ensure that the goals of uniformity and certainty underlying the act are met.

In implementing section 307 of the act, to avoid any suggestion of an unconstitutional delegation to states to enforce the (Federal) act, FDA retains full authority to advise states of what FDA believes is the proper interpretation of any of the sections of the act that they may seek to enforce. If FDA advises a state that its proposed

action is inconsistent with FDA's interpretation, FDA believes section 307 of the act requires that the state conform its interpretation to FDA's.

II. Paperwork Reduction Act

In accordance with the Paperwork Reduction Act of 1980 (44 U.S.C. Chapter 35), the provisions of § 100.2 *State enforcement of Federal regulations* relating to submission of information to FDA will be submitted for approval to the Office of Management and Budget (OMB). These provisions will not be effective until FDA obtains OMB approval. FDA will give notice of OMB approval of these requirements in the **Federal Register** as part of any final rule that is based on this proposal.

III. Environmental Impact

The agency has determined under 21 CFR 25.24(a) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore neither an environmental assessment nor an environmental impact statement is required.

IV. Economic Impact

FDA has examined the economic implications of the proposed rule pertaining to part 101 requirements as required by Executive Order 12291 and the Regulatory Flexibility Act. Executive Order 12291 compels agencies to use cost-benefit analysis as a component of decisionmaking and the Regulatory Flexibility Act requires regulatory relief for small businesses where feasible.

This proposed regulation codifies conditions under which states can enforce certain sections of the act and provides a format for notification of FDA of a state's intent to enforce those provisions. FDA has no information as to the cost of the required submission by states, although the information requested is the minimum required for notification purposes. If, for example, the required paperwork costs $100 per state action to prepare, it would take over one million enforcement actions to cause this proposed requirement to become a major rule, an unlikely event.

Because very little paperwork is required to be submitted, FDA concludes that this proposed rule is not a major rule as defined by Executive Order 12291. In addition, FDA certifies that this action will not result in a significant economic impact on a substantial number of small entities as defined by the Regulatory Flexibility Act.

V. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VI. Effective Date

The agency intends to issue final regulations pertaining to the state enforcement provisions of the 1990 amendments by November 8, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective November 8, 1992, in accordance with the requirements of the 1990 amendments.

List of Subjects in 21 CFR Part 100

Administrative practice and procedure, Food labeling, Foods.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 100 be amended as follows:

PART 100—GENERAL

1. The authority citation for 21 CFR Part 100 is revised to read as follows:

Authority: Secs. 201, 301, 307, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 337, 342, 343, 348, 371).

2. Section 100.2 is added to Subpart A to read as follows:

§ 100.2 State enforcement of Federal regulations.

(a) Under section 307 of the Federal Food, Drug, and Cosmetic Act, a state may bring, in its own name and within its own jurisdiction, proceedings for the civil enforcement, or to restrain violations, of sections 401, 403(b), 403(c), 403(d), 403(e), 403(f), 403(g), 403(h), 403(i), 403(k), 403(q), or 403(r) of the act if the food that is the subject of the proceedings is located in the state.

(b) No proceeding may be commenced by a state under paragraph (a) of this section:

(1) Before 30 days after the state has given notice to the Food and Drug Administration (FDA) that the state intends to bring such proceeding.

(2) Before 90 days after the state has given notice to FDA of such intent if FDA has, within such 30 days, commenced an informal or formal enforcement action pertaining to the food which would be the subject of such proceeding.

(3) If FDA is diligently prosecuting a proceeding in court pertaining to such food, has settled such proceeding, or has settled the informal or formal enforcement action pertaining to such food.

(c) A state may intervene as a matter of right, in any court proceeding described in paragraph (b)(3) of this section.

(d) The notification that a state submits in accordance with paragraph (b) of this section should include the following information and be submitted in the following recommended format:

(Date)

Name of State agency———

Post office address ———

Street address ———

City, State, and ZIP code ———

Name of products(s) covered by the notification

Reporting official, title, and telephone No.

FAX No.———

Agency contact (if different from reporting official), title, and telephone No.

Director, Division of Regulatory Guidance (HFF–310), Center for Food Safety and Applied Nutrition, Food and Drug Administration,
200 C St. SW.,
Washington, DC 20204.

Dear Sirs: The undersigned, _____, submits this letter of notification pursuant to section 307(b)(1) of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 337(b)(1)) with respect to

---

(name of products covered by the notification and the enforcement action that is to be initiated)

Attached hereto, and constituting a part of this letter of notification are the following:

A. The name of the product.

B. The type and size of each product container.

C. Copy of the label and labeling of the product.

D. Manufacturing code (if applicable).

E. Name and address of firm responsible for violations.

F. Name and address of manufacturer or distributor responsible for violations.

G. Name and address of parent firm (if known).

H. Reason for the anticipated state enforcement action (list specific violations, including sections of the law violated).

I. Name of firm against which action is anticipated (if applicable).

Yours very truly,
Reporting Agency
By ———

(Indicate authority)

(e) The letter of notification should be signed by a State official authorized by

the State to institute the contemplated enforcement actions.

(f) The letter of notification should be sent to the Division of Regulatory Guidance (HFF–310), Center for Food Safety and Applied Nutrition, Food and Drug Administration, 200 C St. SW., Washington, DC 20204, FAX number 202–472 1542.

(g) FDA will notify the state of the date on which its letter of notification was received by FDA, Center for Food Safety and Applied Nutrition, Division of Regulatory Guidance (HFF–310) (within 2 working days after date of receipt). This date will be the date of notification for the purposes of paragraph (b) of this section.

(h) The Director, Division of Regulatory Guidance, Office of Compliance, Center for Food Safety and Applied Nutrition, Food and Drug Administration, will respond to the State's notification within 30 days of the date of notification by advising:

(1) Whether FDA has commenced an informal or formal enforcement action pertaining to the food that is the subject of the notification; or

(2) Whether FDA is prosecuting a proceeding in court pertaining to such food, has settled such proceeding, or has settled informal or formal enforcement action pertaining to such food.

(i) Information contained in State notification letters required by this section shall be exempt from public disclosure to the same extent to which such information would be so exempt pursuant to §§ 20.61, 20.64, and 20.88 of this chapter.

(j) *Definitions.* (1) "Informal enforcement actions" include warning letters, recalls, detentions, or other administrative enforcement actions that pertain to the food in question.

(2) "Formal enforcement actions" include seizures, injunctions, prosecutions, or other judicial enforcement actions that pertain to the food in question.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

RIN 0905–AB67

Labeling; General Requirements for Health Claims for Food

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing general requirements pertaining to: (1) The use of health claims that characterize the relationship of a food component to a disease or health-related condition on the labels and in labeling of both conventional foods and dietary supplements, and (2) the content of petitions regarding the use of such health claims pertaining to specific substances in food. This proposal is issued in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims. It supersedes in all respects FDA's reproposed rule concerning health messages (February 13, 1990, 55 FR 5176). Elsewhere in this issue of the **Federal Register**, FDA is issuing proposals that respond to the 1990 amendments directive that the agency consider 10 topics associating nutrients with diseases or health-related conditions. Those proposals have been developed in accordance with the general principles of the proposed requirements in this document.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following publication of a final regulation pertaining to health claims in food labeling in accordance with requirements of the 1990 amendments.

ADDRESSES: Written comments to the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, 301–443–1751.

FOR FURTHER INFORMATION CONTACT: Victor P. Frattali, Center for Food Safety and Applied Nutrition (HFF–261), Food and Drig Administration, 200 C St., SW., Washington, DC 20204, 202–245–1064.

SUPPLEMENTARY INFORMATION:

I. Background

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101–535). This new law amends the Federal Food, Drug, and Cosmetic Act (the act) in a number of important ways. One of the most notable aspects of the 1990 amendments is that they confirm FDA's authority to regulate nutrient content claims and health claims on food labels and in labeling. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards contained in regulations established under section 403(r)(1)(B) of the act (21 U.S.C. 343 (r)(1)(B))

The enactment of the 1990 amendments reflects a determination by Congress that an orderly and accountable process is needed to control the dissemination of information concerning the relationship between diet and disease or other health-related conditions on the food label and in labeling. Congress characterized this need as "compelling" (Ref. 1). FDA is proposing general requirements to ensure that this information in food labeling will be valid, truthful, nonmisleading, and useful for consumers.

The agency fully recognizes the importance of conveying to American consumers information on the value of improved nutrition to help achieve or maintain good health. FDA is committed to facilitating the provision of such information wherever adequate scientific evidence confirms the validity of the information.

II. Regulatory History

For many years, FDA has permitted firms to label foods with truthful, nonmisleading information about the nutrient content of food. In the past, however, the agency did not permit firms to provide consumers with information on the label or in labeling concerning how the food may be used to affect a disease or health-related condition. FDA generally took a position that including disease-related information on food labeling resulted in the food being a drug within the meaning of the act. The act (section 201(g)(1)(B)) defines a drug, in part, as "articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of a disease in man * * *" (21 U.S.C. 321(g)(1)(B)). Thus, the agency has viewed mention of a disease on a food label as evidence that the product was intended to be used as a drug.

In addition, in the **Federal Register** of March 14, 1973 (38 FR 6950 at 6951), FDA promulgated regulations that provided, in part, that a food shall be deemed to be misbranded if its labeling represents, suggests, or implies that the food, because of the presence or absence of

certain dietary properties, is adequate or effective in the prevention, cure, mitigation, or treatment of any disease or symptom (currently, 21 CFR 101.9(i)(1)). This provision reinforced the agency's policy concerning disease-related information on food labels. In the **Federal Register** of August 4, 1987 (52 FR 28843) (the 1987 proposal), however, FDA proposed to change its policy to permit the use on food labeling of health messages (in this proposal, the term "health claim" is used in place of "health message" for consistency with terminology used in the 1990 amendments). The agency was responding to the developing scientific data on the relationship between the nutrient content of the diet and disease.

The 1987 proposal proposed to amend nutrition labeling regulations in § 101.9 to permit health claims when:

(1) They are truthful and not misleading;

(2) They are supported by valid, reliable, and publicly available scientific evidence derived from well-designed and well-conducted studies consistent with generally accepted scientific procedures and principles performed and evaluated by persons qualified by expertise and training in the appropriate disciplines;

(3) They are consistent with generally recognized medical and nutritional principles for a sound total dietary pattern; and

(4) The food bears nutrition information in accordance with the requirements of § 101.9.

The agency advised in the 1987 proposal (52 FR 28843) that firms could make health claims consistent with the proposed provisions without prior FDA approval. Thus, FDA created a "safe harbor" from agency enforcement action for such claims.

After publication of the 1987 proposal, health claims began appearing on foods with increasing frequency. In a number of situations, these claims conformed only partially with the proposed provisions. Some manufacturers took advantage of the broad manner in which the proposal was written by making drug claims on products and then, when challenged by FDA, asserting that these claims were consistent with how food could be labeled under the proposal.

Because of the wide divergence of opinion expressed in comments that responded to this proposal, the agency concluded that the issues raised by this proposal could not be resolved without additional and more specific comments from interested persons. In recognition of this need, FDA solicited additional comments on health claims in an advance notice of proposed rulemaking (ANPRM) published in the **Federal Register** of August 8, 1989 (54 FR 32610), that requested public comment on a wide range of food labeling issues. On December 7, 1989, FDA held a public hearing in Seattle at which the topic of health claims was a prime focus.

Based on the comments on the August 1987 proposal, on the August 1989 ANPRM, and at the public hearing, FDA withdrew the August 1987 proposal and published a reproposal in the **Federal Register** of February 13, 1990 (55 FR 5176) (the 1990 reproposal), stating that the former proposal was superseded in all respects. The agency stated that the 1987 proposal was too broadly written and allowed some manufacturers to take advantage of it by making drug claims on health fraud products. The 1990 reproposal proposed to more narrowly define appropriate health claims and offered criteria to be met to allow a claim. Further, the agency revoked the advisory opinion in the 1987 proposal that permitted firms to make health claims on food labeling where the claims were consistent with the proposal. The agency advised that, pending adoption of a final rule, there would be no "safe harbor" for any health claim in food labeling, and that any health claim may subject a food product to regulatory action.

However, the agency also set forth in the 1990 reproposal an interim enforcement policy that provided general guidance as to how the agency would likely exercise its enforcement discretion regarding health claims until a final rule was promulgated (55 FR 5176 at 5184). The agency stated that manufacturers could continue to include health claims on their products, but that FDA would scrutinize them on a case-by-case basis and exercise its enforcement discretion in deciding when it would bring a regulatory action.

FDA set out four basic principles that it said would guide its exercise of enforcement discretion. It also pointed to six topic areas about which significant evidence appeared to exist. The agency stated that claims regarding these topic areas were least likely to run the risk of regulatory action. In addition, FDA stated that a claim that used the phrases "may reduce the risk" or "may forestall the premature onset" would be less likely to be subject to regulatory action than one that more firmly asserted that a relationship exists between a food component and a disease.

After publication of the 1990 reproposal, FDA sent regulatory letters to a number of firms whose products bore labeling that contained false or misleading health claims. Most firms contacted made appropriate changes in their labels and labeling.

FDA received more than 200 comments on the 1990 reproposal from consumers, health professionals, industry, academia, government agencies, and organizations representing consumers, industry, and health professionals. Relevant comments are addressed throughout this document in locations appropriate for their content.

III. The 1990 Amendments

The 1990 amendments address health claims by amending the act to add section 403(r). This section specifies, in part, that a food is misbranded if it bears a claim that expressly or by implication characterizes the relationship of certain nutrients to a disease or health-related condition unless the claim meets the requirements of a regulation authorizing its use (section 403(r)(1)(B) of the act). Section 403(r) also directs FDA to issue regulations authorizing health claims for nutrients in conventional foods and in dietary supplements in appropriate circumstances. In addition, the 1990 amendments (section 3(b)(1)(A)(vi) and (b)(1)(A)(x)) require that FDA determine whether health claims respecting 10 specific nutrient disease topics are appropriate under the requirements of the act.

A. FDA Authority

Several comments on the February 13, 1990 reproposal questioned the agency's authority to regulate health claims. Congress specifically recognized these questions in the legislative history of the 1990 amendments (Ref. 1). Enactment of the 1990 amendments renders these comments moot. The agency now has clear authority to regulate all health claims on food.

B. Conversion to New Statutory Requirements

The passage of the 1990 amendments marks the beginning of a period in which FDA is endeavoring to convert the general requirements of the new law into specific, usable, and enforceable regulations. The issuance of this proposal, which supersedes the 1990 proposal in all respects, is an important step in this transition. During this period of transition, FDA is responsible for protecting the integrity of the food label.

The agency advises that it intends to evaluate any health claims that appear in labeling on a case-by-case basis. FDA is prepared to take action against products that bear false or misleading health claims or claims that evidence an intent that the product is to be used as a

drug but has not been approved for that use.

C. Statutory Provisions on Health Claims

Section 403(r)(1)(B) of the act identifies the substances that may be the subject of a health claim, that is, those nutrients of the type required by section 403 (q)(1) or (q)(2) of the act (new provisions concerning nutrition labeling added by the 1990 amendments) to appear on the label or labeling of a food and those present in dietary supplements of vitamins, minerals, herbs, or other similar nutritional substances (section 403(r)(5)(D) of the act).

Section 403(q)(1) of the act provides that nutrition labeling shall include information on the total number of calories derived from any source; the number of calories derived from total fat; the amount of total fat, saturated fat (i.e., saturated fatty acids), cholesterol, sodium, total carbohydrates, complex carbohydrates, sugars, dietary fiber, and total protein; and any vitamin, mineral, or other nutrient required to be placed on the label before October 1, 1990, if the Secretary determines that such information will assist consumers in maintaining healthy dietary practices. In the agency's supplementary proposal on the mandatory status of nutrition labeling published elsewhere in this issue of the **Federal Register**, FDA is proposing to require the listing of vitamin A, vitamin C, calcium, and iron under this provision. Section 403(q)(2) of the act provides that the agency may require information concerning additional nutrients in nutrition labeling when the Secretary concludes that the information will assist consumers in maintaining healthy dietary practices. Consequently, other vitamins and minerals may be required to be listed on the label in the future.

To assure the validity of health claims, Congress enacted a scientific standard in section 403(r)(3)(B)(i) of the act for conventional food that provides that the Secretary (and by delegation, FDA) shall promulgate regulations authorizing nutrient health claims only if the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) supports the claim, and there is significant scientific agreement among qualified experts that the claim is supported by such evidence. For health claims for dietary supplements of vitamins, minerals, herbs, or other similar nutritional substances, Congress provided that the standard for the validity of such claims must be established by the Secretary (and by delegation, FDA) (section 403(r)(5)(D) of the act).

Where claims can be justified for conventional food, section 403(r)(3)(B)(ii) of the act requires that a regulation describe the relationship between the nutrient and the disease or health-related condition and describe the significance of the nutrient in affecting the disease or health-related condition. Section 403(r)(3)(B)(iii) of the act requires that the claim be "stated in a manner so that the claim is an accurate representation of the matters set out in subclause (ii) and so that the claim enables the public to comprehend the information provided in the claim and to understand the relative significance of such information in the context of a total daily diet."

Under section 403(r)(3)(A)(ii) of the act, health claims may only be made on foods that do not contain nutrients in an amount that increases "to persons in the general population the risk of a disease or health-related condition which is diet related, taking into account the significance of the food in the total daily diet * * *." However, this provision goes on to say that the Secretary may by regulation permit such a claim if he or she finds that such a claim would assist consumers in maintaining healthy dietary practices, and he or she provides for disclosure of the presence of the nutrient in conjunction with the claim.

In addition, the 1990 amendments revise the definition of "drug" in section 201(g)(1) (21 U.S.C. 321(g)(1)) of the act to provide that food for which a health claim is made in accordance with the requirements of section 403(r) of the act is not a drug solely because the label or labeling contains such a claim.

D. Same Scientific Standard for Dietary Supplements

FDA is proposing the same scientific standard for dietary supplements of vitamins, minerals, herbs, and other similar nutritional substances as for all other foods. The agency recognizes that proposing the same standard for conventional food and dietary supplements is contrary to the view expressed by some members of Congress, and by some individuals in comments to the agency in response to a notice in the **Federal Register** of March 14, 1991 (56 FR 10906), on petition procedures, that a separate, more lenient standard should be established for supplements. However, FDA has reviewed the legislative history concerning section 403(r)(5)(D) and has tentatively concluded that Congress did not intend that the agency be forced to adopt a different standard for these products (Refs. 2 and 3). Instead, the exemption on its face gives the agency the discretion to adopt any appropriate scientific standard for supplements. The exemption gives the agency the same discretion with respect to establishing a procedure under which claims may be made.

The statement of House Floor Managers (Ref. 3), addresses section 403(r)(5)(D) of the act by stating, in part:

> The Senate version of the bill, which we are voting on today, retains this standard for all foods except vitamins, minerals, herbs, and other similar nutritional substances (referred to below as "vitamins"). The bill requires that vitamins that include claims defined under section 403(r)(1)(B) shall be subject to a "procedure and standard" defined by the Secretary in regulations that require an evaluation of the validity of the claim. The FDA is given the discretion to define both the procedure and the standard because the principals in the Senate could not agree on the appropriate procedure or the appropriate standard.
>
> It is obvious from the language that the agency could adopt the same procedure and standard that Congress has adopted for disease claims on food other than vitamins; it is also obvious that it could adopt a stronger standard for vitamins, minerals, herbs, and other similar nutritional substances. (Congressional Record, July 30, 1990).

In addition, the Metzenbaum-Hatch managers' statement in the Senate (Ref. 2) addresses section 403(r)(1)(B) of the act by stating, in part:

> The purpose for the different handling of conventional food products and dietary supplements is to provide the Secretary flexibility in the development of the procedure and standard for health claims for dietary supplements. (Congressional Record, October 24, 1990).

Thus, both the Senate and the House of Representatives agreed that FDA has the flexibility to adopt the standard and procedure for dietary supplements that appears appropriate to the agency.

Regarding the ability of the Secretary of Health and Human Services (and by delegation, FDA) to determine the appropriate procedure and standard for dietary supplements, the Metzenbaum-Hatch managers' statement further says that the following two factors should be taken into account:

> The rapid pace of scientific advance linking nutritional substances to the maintenance of long-term human health and prevention of long-term disease; and
>
> The ways in which dietary supplements are marketed and used by individuals differently from conventional food products. (Congressional Record, October 24, 1990).

Some consumers seek to ensure that the nutrient content of their diet is

adequate through conventional foods, others through dietary supplements. Ultimately, however, it is the nutrient content of the diet that is significant, not its source. For this reason, neither the pace of scientific advances with respect to nutritional substances nor the way individuals use supplements justifies different treatment for dietary supplements than for conventional foods.

From the Senate, there were mixed opinions as to what the agency should do with this flexibility. In the October 24, 1990 Congressional Record, on page S16611 (Ref. 2), Senator Hatch, one of the primary authors of the amendments made by the Senate, stated:

> By their very nature, the dietary supplements must be marketed so that the consumer is informed of the health or disease-prevention benefits that may be conferred. Greater flexibility is thus required to permit communication of these benefits. This increased regulatory flexibility is also mandated by the very rapid pace of scientific advances here and abroad linking the prevention of long-term disease to improved nutritional supplementation. For these reasons, a more lenient standard for dietary supplement[s] is envisioned. (Congressional Record, October 24, 1990).

However, in this same Congressional Record, (Ref. 2), Senator Metzenbaum, the other primary author of these amendments, stated:

> * * * It is my view that there is no reason to do anything other than utilize the same procedure and standard for dietary supplements.
>
> Whatever approach the Secretary takes, he must establish a system that evaluates the validity of health claims for dietary supplements. The system must be based on the same considerations that guide other agency decisions: Public health, sound scientific principles and consumer fraud.

The statement of House Floor Managers also addresses this issue (Ref. 3):

> * * * Whatever approach the agency takes, it must adopt a system that evaluates the validity of any disease claims made with respect to these substances. Its system must be based on considerations of public health and consumer fraud. As in every similar decision made by the agency today, we fully expect that the agency's evaluation of disease claims made with respect to vitamins will be based on sound scientific principles.
>
> There is a great potential for defrauding consumers if food is sold that contains inaccurate or unsupportable health claims. The potential is just as great for vitamins as it is for other products. In our view, vitamins and other substances covered by this provision should be subject to at least as strong a standard as is applicable to other foods that contain claims that the food will treat a disease or health condition.

In the absence of clear Congressional direction about the way in which FDA should use the flexibility it has, the agency believes that it is appropriate to propose the same scientific standard and procedure for supplements as is mandated for conventional foods. If the agency were to adopt a more lenient standard and procedure for supplements, FDA believes that there would be a significant potential for consumer confusion when confronted with a situation in which there would be health claims for substances when they are present in supplements but not when they are present in conventional foods. Furthermore, FDA believes that a standard and procedure that is more lenient than that provided in section 403(r)(3)(B)(i) would not provide a basis on which to evaluate the validity of claims, which both the House Managers (Ref. 3) and at least one Senate author (Ref. 2) stated should be the goal of the approach that the agency adopts.

Nor does FDA consider a more stringent standard to be necessary. The standard that it is proposing for dietary supplements is the same as that which it proposed for all foods in 1990. FDA believes that this standard strikes an appropriate balance between the desire to make information available and the desire to ensure that that information is truthful, usable, and not misleading.

For FDA, a significant measure of whether a claim is valid is whether the evidence that supports that claim has stood the test of exposure to scientific scrutiny. Such scrutiny is a critical element in deciding whether any proposition is based on sound science. FDA cannot ignore such a critical element when deciding whether consumers should be advised that a particular diet-disease relationship exists. Such scrutiny is specifically provided for in the standard set forth in section 403(r)(3)(B)(i) of the act. Therefore, FDA believes that this standard should be applied in judging any health claim, whether for conventional foods or dietary supplements.

FDA does not believe that it could have a significant level of comfort, the standard for appraising claims suggested in the House Report (Ref. 1), about the validity of claims if it adopted any of the more lenient approaches suggested in comments to the March 14, 1991 notice. FDA has an obligation under the act to assure not only that claims comply with section 403(r) of the act but also that they are truthful and not misleading under section 403(a) of the act. Suggestions that the agency should delegate the primary responsibility for evaluating the validity of claims for herbs to industry committees are not consistent with this agency's responsibility. Of course, industry may, if desired, work through committees to prepare well-supported petitions for submission to FDA. However, FDA would still have the ultimate obligation of ensuring that there is compliance with the act.

FDA also does not agree with comments that suggested that it should adopt a regulatory framework for evaluating health claims for supplements that establishes three categories of claims, each of which would be subject to a different level of validity substantiation and different procedures. As suggested, Category I claims would be subject to the same validity requirements as established for conventional food. Category II claims would pertain to claims for which there is substantial scientific evidence but not yet significant scientific agreement. Category III claims would pertain to claims for which there is sound scientific evidence, which on balance supports the claim but is more preliminary in nature. Categories II and III claims would be subject to a certification and notification procedure and would not have to be affirmatively authorized by regulation.

FDA does not believe that the suggested certification and notification procedure for Categories II and III claims are adequate or appropriate under section 403(r)(5)(D) of the act. As discussed above, the legislative history from both the Senate and the House points to the fact that the procedure and standard that FDA is to establish under this section should evaluate the validity of health claims. Yet, the procedure suggested in the comment would not provide the agency with a full opportunity to do so. Under the procedure suggested in the comment, the greater the question about the validity of the claim, the less opportunity that FDA would have to review it. Such a system would not be fair to consumers, who would be exposed to claims whose validity had not been evaluated by FDA, or the manufacturers of conventional foods, who would be subject to the much higher congressionally mandated standard. For these reasons, under the discretion granted the agency by section 403(r)(5)(D), FDA is rejecting the comment.

E. FDA Requests For Data

In the **Federal Register** of March 28, 1991 (56 FR 12932), FDA published a notice requesting scientific data and information on the ten nutrient-disease topics that paragraphs (vi) and (x) of

section 3(b)(1)(A) of the 1990 amendments require FDA to consider. FDA established ten dockets for information relating to these topics, as follows: Calcium and osteoporosis, 91N–0094; sodium and hypertension, 91N–0095; lipids and cardiovascular disease, 91N–0096; lipids and cancer, 91N–0097; dietary fiber and cancer, 91N–0098; dietary fiber and cardiovascular disease, 91N–0099; folic acid and neural tube defects, 91N–0100; antioxidant vitamins and cancer, 91N–0101; zinc and immune function in the elderly, 91N–0102; and omega-3 fatty acids and heart disease, 91N–0103. The compiled scientific data and information were considered by FDA in its development of the proposed regulations pertaining to specific health claims that are published elsewhere in this issue of the **Federal Register**. FDA generally will address that data and information that it received in response to the March 1991 notice in the documents on those proposed regulations.

F. How Claims Are Made

When FDA determines on the basis of its review of the evidence on a nutrient-disease relationship, as it has with respect to some of the topics that are the subject of the specific documents published elsewhere in this issue of the **Federal Register**, that a health claim should be authorized, the agency will propose a specific regulation permitting a claim in subpart E of 21 CFR part 101. (FDA is proposing to create subpart E in this document.) The proposal will clearly identify the elements that must be included in the claim to assure its validity. In addition, the agency will illustrate the claim that is permitted through an example of an appropriate claim (referred to as a "model health claim"). If, after its review of comments, FDA decides to issue a final regulation based on that proposal, firms will be able to make claims that comply with that regulation on appropriate foods. Firms will not be required to use the language in the model claim but will be free to develop their own specific claims within the terms of the regulation.

In the authorizing regulation, FDA will set out requirements to ensure that any claim made under it will fully reflect the scientific facts justifying the claim. These requirements will not only describe the nutrient-disease relationship but will define other relevant factors, such as nondietary elements (e.g., the need for exercise) and relevant nutrient interactions (e.g., calcium and phosphorus levels in a food).

For conventional foods, many of the elements that will be included in the authorizing regulations will reflect the requirements of the 1990 amendments. As discussed previously, section 403(r)(3)(B)(ii)(I) of the act, which was added by the 1990 amendments, requires that regulations authorizing claims require that those claims describe the relationship between the nutrient and the disease or health-related condition. FDA is applying this requirement in the proposed regulations on health specific claims published elsewhere in this issue of the **Federal Register**. For example, the proposal authorizing a health claim on the relationship between calcium and osteoporosis requires, in part, that the claim explain that adequate calcium intake during adolescence and early adulthood appears to have a positive effect on bone health, and that optimizing peak bone mass during that period may reduce the risk of osteoporotic fracture in old age (see proposed § 101.72(d)(3)).

Section 403(r)(3)(B)(ii)(II) of the act requires that regulations authorizing health claims require that claims describe the significance of the nutrient in affecting the disease or health-related condition. Thus, the proposal concerning calcium and osteoporosis requires, in part, that a claim explain the various factors other than calcium intake that bear on the risk of developing osteoporosis, that is that being a white female or having a family history of fragile bones with aging, places an individual at risk for the development of osteoporosis in later life (see proposed § 101.72(d)(2)).

Further, section 403(r)(3)(B)(iii) of the act requires that the public be able to comprehend the information in the claim and to understand the significance of the information in the context of the total daily diet. Under this requirement, a wide variety of factors may need to be addressed in the claim. For example, the proposal concerning calcium and osteoporosis requires, in part, that claims point out that adequate calcium intake is not enough. The proposal provides that the claim must advise that adequate calcium intake should be accompanied with exercise and maintenance of a balanced diet.

As stated above, section 403(r)(5)(D) [1] of the act directs FDA to establish a procedure and standard to assure the validity of health claims for dietary supplements. In section III.D. of this document, FDA discussed why dietary supplements should be subject to the same scientific standard, and procedure for assessing conformity with the standard, that is used for conventional foods. The agency has tentatively determined that it is also appropriate to subject dietary supplements to the same procedures with respect to how claims are made and how they are petitioned for as those that apply to conventional foods. The agency has reached this tentative conclusion based on three factors:

1. FDA has an obligation to ensure that food labeling is truthful and not misleading. Under the act, a claim can be misleading, and thereby misbrand the food, based on the information that it does not include as well as the information that it does include. The agency believes that the procedures that it is proposing are necessary to ensure that claims that are made are fully informative to consumers. Because claims for dietary supplements must be as informative as claims for conventional foods, FDA believes that it is appropriate to subject the former claims to the same procedures as the latter.

2. As stated above, FDA has an obligation to treat all segments of the regulated food industry with fairness. If dietary supplements were subject to different rules, whether with respect to the procedure for assessment of conformity with the scientific standard or to the manner in which claims are made, there is a possibility that supplements could be made to appear somehow superior to conventional foods that contain the same nutrient. Such an appearance would not only be untrue, it would be unfair to firms producing conventional foods. FDA knows of no differences in the marketing or use of dietary supplements and conventional foods that would compel a different result.

3. As stated previously in the discussion of the scientific standard in section III.D. of this document, some consumers seek to ensure that the nutrient content of their diet is adequate through conventional foods, others through dietary supplements. Ultimately, however, it is the nutrient content of the diet that is significant, not its source. For this reason also, the pace of scientific advances with respect to nutritional

[1] FDA notes that section 403(r)(3)(A) of the act states "Except as provided in paragraph (5)," and that that provision relates to only "a procedure and standard." Thus, it is possible that various aspects of how health claims on dietary supplements are made are governed by section 403(r)(3) of the act. However, because FDA, in exercising its discretion, has tentatively decided under section 403(r)(5)(D) of the act that dietary supplements should be subject to the same requirements that conventional foods are subject to under section 403 (r)(3) and (r)(4), FDA finds that the question of the extent to which the latter sections apply to dietary supplements is moot.

substances does not justify different treatment for dietary supplements than for conventional foods.

In sum, it is the nutrient that is significant, not its source. To ensure that labeling is truthful and not misleading, the same substantive rules should thus be applied to conventional foods and to dietary supplements.

IV. Proposed Provisions

A. Definitions

FDA is proposing the following definitions in § 101.14(a) to clarify the meaning of specific terms used in this proposed rule.

1. Health Claim

FDA is proposing to define "health claim" as any claim made on the label or in labeling of a food, including a dietary supplement, that expressly or by implication characterizes the relationship of any substance to a disease or health-related condition. Such claims could include "third party" endorsements, written statements (e.g., a brand name including a term such as "heart"), symbols (e.g., a heart symbol), or vignettes. This definition is derived almost directly from section 403(r)(1)(B) of the act, although it has been modified slightly to incorporate that section's reference to section 403(r)(5)(D) of the act.

The definition includes examples of implied claims and expressly limits them to those statements, symbols, vignettes, or other forms of communication that a manufacturer intends, or would be likely to be understood, to assert a direct beneficial relationship between the presence or level of any substance in the food and a health or disease-related condition. The definition is intended to make clear that vignettes or other forms of communication that depict the general wholesomeness of a product or other attributes that do not involve more specifically the relationship between a substance in the food and a health or disease-related condition are not health claims for the purpose of this regulation.

FDA recognizes that there is often ambiguity in the message conveyed by a logo or symbol, such as the heart symbol that is often used on labels and restaurant menus. FDA specifically invites comment on the appropriate meaning or warnings to be attributed to the heart symbol and other currently used logos and symbols. Should they be regarded as nutrient content descriptors, health claims, or both? Should they be defined as such by FDA and, if so, how? FDA's goal in considering these questions will be to retain the use of logos and symbols where they are useful in communicating health-related information to consumers but to guard against their use in a manner that would be confusing or misleading to consumers.

While the act focuses on the substance-disease relationship, it is clear that the Congress was concerned about any disease claims that are made on food (Ref. 1). In reviewing the evidence on the 10 topic areas, however, FDA has become aware that there may be certain relationships between foods and diseases that are supported by the available evidence but that cannot be attributed to a particular nutrient. For example, the scientific evidence shows that diets high in whole grains, fruits, and vegetables, which are low in fat and rich sources of fiber and certain other nutrients, are associated with a reduced risk of some types of cancer. The available evidence does not, however, demonstrate that it is total fiber, or a specific fiber component, that is related to the reduction of risk of cancer. The question is thus whether, to fulfill Congress's intent in the 1990 amendments, FDA should regulate claims about apparent food-disease relationships and, if so, how it should do so. For example, the recent National Cancer Institute "Five-A-Day" program constitutes dietary guidance and not a health claim (Ref. 1). It could appear on the label of foods that appropriately fall within the terms of the dietary guidance. FDA requests comments on what regulatory approaches, if any, with respect to these types of claims would be most consistent with the act's and the agency's goals of assuring both that useful nutritional information is available to consumers, but that the information is scientifically valid and not misleading. The agency also requests comments on whether, if the agency should regulate such claims, it should do so under proposed § 101.14 or under the general regulatory regime of a label needing to be truthful and not misleading.

2. Substance

In proposed § 101.14(a)(2), FDA is proposing to define the term "substance" to facilitate identification, within the proposed regulation and in this document, of all food components that are candidates to be the subject of a health claim. Thus, FDA is proposing to define the term "substance" to include any component of a conventional food or of a dietary supplement of vitamins, minerals, herbs, or other nutritional substances. Reference in the definition to "a dietary supplement of vitamins, minerals, herbs, or other similar nutritional substances" incorporates the statutory language in section 403(r)(5)(D) of the act, which directs the agency to establish a procedure and standard for claims for dietary supplements.

3. Nutritive Value

FDA is proposing to define the term "nutritive value" to facilitate use of one of the criteria under which a substance is a food and thus appropriately the subject of a health claim. FDA proposes to define the term "nutritive value" as value in sustaining human existence by such processes as promoting growth, replacing loss of essential nutrients, or providing energy. FDA developed this definition based on the common meaning of the words that make up this term.

"Nutrient" is defined in the *Random House Dictionary of the English Language* as "* * * [a substance capable of] providing nourishment or nutriment." This dictionary defines "nutriment" as "any substance or matter that, taken into a living organism, serves to sustain it in its existence, promoting growth, replacing loss, and providing energy." The dictionary defines "nourishment" as "something that nourishes; food, nutriment, or sustenance." Further, the dictionary defines "nourish" as "to sustain with food or nutriment; supply with what is necessary for life, health, and growth." The agency's proposed definition for "nutritive value" encompasses these common definitions except that the definition is specific for humans, for consistency with section 403(r)(1) of the act.

Use of the phrase "such processes as" in the proposed definition conveys a measure of flexibility that the agency believes is necessary for evaluating future petitions. Within the context of the daily diet, there may be a wide array of substances that could logically supply nutritive value. For example, if a substance as a component of a food is of value for cellular functions by providing catalytic support for protective reactions (e.g., inhibiting harmful processes), that substance could be viewed by FDA as providing nutritive value. FDA also advises that any substance that is identified as a nutrient in section 403(q)(1)(C), (q)(1)(D), or (q)(1)(E) of the act conforms to the proposed definition of "nutritive value."

4. Dietary Supplement

FDA is proposing to define "dietary supplement" as a food, other than a conventional food, that supplies a component with nutritive value to supplement the diet by increasing the

total dietary intake of that substance. A dietary supplement includes a food for special dietary use within the meaning of § 101.9(a)(2) that is in conventional food form.

This term, although used in section 403(r)(5)(D) of the act, is not defined in the 1990 amendments. In the past, FDA has taken a position that the term "dietary supplement" applied only to supplements composed of essential nutrients. However, FDA is not proposing to limit the definition in § 101.14(a) in this way because section 403(r)(5)(D) of the act includes dietary supplements of "herbs" which, as foods, are generally used for flavor or aroma rather than for nutritive value. Herbs contain few essential nutrients, and those essential nutrients that are present are seldom present in significant amounts on a per serving basis. In addition, the legislative history indicates that the term "other nutritional substances" could include a number of substances that have not been shown to be essential (Ref. 2).

5. Disqualifying Nutrient Levels

Section 403(r)(3)(A)(ii) of the act provides that a health claim may only be made for a food that does not contain, as determined by regulation, a nutrient in an amount that increases to persons in the general population the risk of a disease or health-related condition that is diet related, taking into account the significance of the food in the total daily diet. There is no indication in the legislative history of this provision as to what Congress considered to be an amount of a nutrient in a specific food that would increase the risk of a disease.

The statute provides the same standard in section 403(r)(2)(B)(ii) of the act for nutrient content claims, with the requirement that the label or labeling of any food that contains a nutrient at a level that increases the risk of a diet-related disease or health condition shall identify that nutrient in immediate proximity to the claim. A similar requirement for a cholesterol content claim is in section 403(r)(2)(A)(iii)(II) of the act. In referring to these levels for nutrient content claims, FDA uses the term "disclosure levels" (see companion document on nutrient content claims published elsewhere in this issue of the **Federal Register**). The disclosure level for a nutrient for a content claim is the same as the disqualifying level for the nutrient for a health claim.

FDA is defining "disqualifying nutrient levels" (referred to in this document as "disqualifying levels") in proposed § 101.14(a)(5). FDA is proposing to define "disqualifying nutrient levels" as the levels of total fat, saturated fat, cholesterol, or sodium in a food above which the food will be disqualified from making a health claim. The agency is proposing that the disqualifying levels are 11.5 grams (g) of fat, 4.0 g of saturated fat, 45 milligrams (mg) of cholesterol, or 360 mg of sodium per reference amount commonly consumed, per labeled serving size, and per 100 g. Any one of the levels, on a per reference amount commonly consumed, a per labeled serving size, or a per 100 g basis, will disqualify a food from making a health claim.

These disqualifying levels are intended to ensure that a food that bears a health claim does not at the same time contain a nutrient at a level that increases the risk of a disease. Because Congress did not identify any specific nutrients that were of concern, consistent with section 403(r) of the act, FDA considered the risk presented by nutrients of the type required by section 403(q)(1) and (q)(2) of the act to be in the label or labeling of food. Of these, nutrients, total fat, saturated fat, cholesterol, and sodium have been associated with increased risk of disease. For maintenance of good health, recommended limits for dietary intake levels have been identified for each of these nutrients (Refs. 5 through 7).

Excessive intake of sugars has been associated with increased risk of tooth decay. However, the specific dietary level at which this increased risk occurs is uncertain, and there is, therefore, no recommended level for dietary intake for sugars. In addition, excessive intake of calories is associated with obesity which is a positive risk factor for a number of diseases. "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 7, hereinafter referred to as "Dietary Guidelines for Americans") recommends that all Americans maintain a healthy body weight. However, the level of calories needed to maintain a healthy weight can vary widely among individuals depending on age, sex, build, and physical activity, and there is no specific recommended level for calories in terms of an absolute number or as a function of the intake of other nutrients. Therefore, FDA cannot identify any single level of calories or sugar in a food that would increase the risk of disease.

Although there are recommended levels for dietary intake for total fat, saturated fat, cholesterol, and sodium, there are no generally recognized levels at which these nutrients in an individual food pose an increased risk of disease. Thus, FDA knows of no established or accepted approach for identifying disqualifying levels for these nutrients. FDA has, therefore, used an approach that is based upon the recommended levels for dietary intake of these nutrients in setting the proposed disqualifying levels because deviation from the recommended levels has been associated with an increased risk of disease.

As discussed in the supplementary proposal on mandatory nutrition labeling published elsewhere in this issue of the **Federal Register**, FDA is proposing to codify the recommended dietary levels for fat, saturated fat, cholesterol, and sodium, as well as for several other nutrients, as Daily Reference Values (DRV). The DRVs reflect current and established scientific evidence related to overall nutrient intake and risk of diet-related disease. They are intended to reflect total dietary intake, not intakes from individual foods. Therefore, to derive disqualifying levels for health claims, FDA had to find a way of translating total dietary intake into nutrient levels in individual foods that could be considered to increase the risk of disease.

To determine the appropriate disqualifying levels based on the DRVs for total fat, saturated fat, cholesterol, and sodium, FDA used an approach based on the number of servings of food in a day and available information on food composition. An estimate for the number of servings of food in an average daily meal pattern is approximately 16 to 20 servings (Refs. 8 through 10). If the nutrients under consideration were evenly distributed, then each food serving in a recommended diet would contain 5 to 6.25 percent of each DRV. However, as expected, analyses of FDA's Regulatory Food Composition Data Base (Ref. 11) revealed that these nutrients are not evenly distributed within foods.

In this approach, FDA considered that a nutrient is found in a food category if over half of the foods in the category contained 2 percent or more of the proposed Reference Daily Intake (RDI) or DRV, as appropriate, for the nutrient. Two percent of the label reference value has been used by the agency in the past as a measurable level of a nutrient in a food. The agency further considered a nutrient to be: (1) ubiquitously distributed if it was found in more than 75 percent of the food categories; (2) moderately distributed if it was found in 51 to 70 percent of the food categories; and (3) not widely distributed if it was found in 50 percent or fewer of the food categories. Total fat, saturated fat, cholesterol, and sodium were found to be in 50 to 70 percent of the food

categories (Ref. 12). If the nutrient is available from approximately 50 to 75 percent of food categories, then it is reasonable to expect that it may be available from perhaps as few as half of the foods/beverages consumed. That is, assuming that as many as 20 foods/beverages are consumed in a day (Ref. 10), it is reasonable to expect that the nutrient may be available from perhaps as few as 10 of the foods/beverages. Consequently, if these nutrients are not available in up to half of the food in a balanced diet, then the remaining half of the foods can contain an average of twice the 5 to 6.25 percent, or 10 to 12.5 percent, of the DRV without causing the daily intake to exceed the DRV for any nutrient. The agency used this result as a starting point for determining the appropriateness of 10 percent of the DRV as the disqualifying level for nutrients in foods.

As an initial calculation, the agency determined that the consumption of 10 foods per day containing 10 percent of the DRV would result in a consumption of 100 percent of the DRV in a day. This level of intake is not considered to constitute a risk for diet-related diseases and suggests that the level of 10 percent is too low as a criterion. The agency then doubled the 10 percent value to 20 percent and determined that, assuming the consumption of 10 foods per day at the level of 20 percent of the DRV, the 20 percent criterion results in consumption of twice the DRV. This level of intake is more than sufficient to constitute risk. Thus, the agency tentatively concluded that the appropriate percent of DRV constituting a risk for individual foods was likely to be found between 10 and 20 percent of the DRV.

Accordingly, with the data base available to the agency, FDA evaluated 10, 15, and 20 percent using two criteria to determine whether the consequences of each as the disqualifying level would be reasonable (Ref. 13). The agency analyzed a list of foods to see which foods would be disqualified from bearing a health claim and which would not, and whether the results made sense from a nutritional standpoint. Foods that contain relatively high levels of one or more nutrients that should be consumed less frequently to maintain a diet that meets the guidelines, should be disqualified by an appropriate criterion. On the other hand, foods that would be helpful in a recommended diet should not be disqualified.

Using this analytic strategy, the agency found that the 10 percent level was too low. A number of foods thought to be useful in maintaining a balanced diet would be disqualified at this level, including many vegetable and cereal products. The 20 percent level was too high. Under it, some foods would be permitted to bear health claims that should not be consumed frequently in a healthy diet, including some shortenings and candies. The results of testing the three different levels demonstrated that a level of 15 percent of the DRV was the most reasonable.

Based on these analyses, FDA is proposing that 15 percent of the DRV per reference amount commonly consumed and per labeled serving size (as discussed in the proposal on serving sizes published elsewhere in this issue of the **Federal Register**) of a food be the disqualifying/disclosure level (i.e., 11.5 g of fat, 4.0 g of saturated fat, 45 mg of cholesterol, and 360 mg of sodium for the subject nutrients). These levels are those above which total fat, saturated fat, cholesterol, and sodium will be deemed to increase risk of a diet-related disease or health condition.

However, an analysis (Ref. 14) also showed that there were some foods that do not exceed the 15 percent DRV level on a per serving basis because of small serving sizes but that contain relatively high concentrations of one or more of the subject nutrients on a caloric basis. The agency believes that nutrient-dense foods like these should not be promoted for increased use in a diet because they do not conform to national guidelines, and that these foods should not bear health claims. Therefore, the agency is proposing to also disqualify a food from bearing a health claim (or require nutrient disclosure for content claims) if the food contains more than 15 percent of the DRV for fat, saturated fat, cholesterol, or sodium per 100 g. Based on analyses using FDA's Regulatory Food Composition Data Base (Ref. 14), foods that might be disqualified from bearing health claims because of this criterion include some dessert toppings, gravies, crackers, cookies, and chocolate candies.

The agency recognizes that the nutrients fat, saturated fat, cholesterol, and sodium are not found in the same number of foods nor are they present in foods at the same level. For instance, sodium is more ubiquitous than cholesterol among food categories, but cholesterol is generally found to be present in a food at higher levels of the DRV than is sodium. Therefore, the agency specifically requests comments on this approach for determining the disqualifying/disclosure levels particularly as it relates to the variations in nutrient distributions among foods and to the appropriateness of establishing different levels for different nutrients.

The agency stresses that disqualification of a food from bearing a health claim does not, and should not, imply that the food cannot be incorporated into a balanced diet. To illustrate this point, one of the dietary guidelines advises American consumers to choose a diet that is low in fat, saturated fat, and cholesterol to achieve the benefit of lowered risk for several diet-related diseases (Ref. 7). It is recognized, however, that some foods containing these dietary lipids, such as meats, milk, cheese, and eggs, are also good sources of high quality protein, certain vitamins, and essential minerals. Although such foods when modified to be low in fat may make it easier for consumers to comply with the dietary guidelines, the unmodified foods can still be part of a healthy diet with judicious selection.

FDA does not intend that the establishment of disqualifying levels, as required by the 1990 amendments, be perceived as the creation of a good-food/bad-food concept. It is not true that a food that qualifies for a health claim is good, while one that does not is bad. Rather, a health claim on a food label is a promise to consumers that including the food in a diet, along with other dietary modifications, will be helpful in attaining the claimed benefit and will not introduce a risk of another disease or health-related condition.

The agency also notes that under section 403(r)(3)(A)(ii) of the act, a claim that would otherwise be disallowed because of a disqualifying level of a nutrient may be permitted by regulation for a food based on a finding that such a claim would assist consumers in maintaining healthy dietary practices and based on a requirement that the presence of the nutrient that would otherwise be disqualifying be prominently disclosed on the label or labeling in proximity to the health claim. The agency is not, however, aware of information to support such a regulation. FDA will address such situations on a case-by-case basis when evaluating potential health claim topics. If there is information to support permitting a claim on this basis, it should be submitted as part of a petition requesting a regulation authorizing a health claim.

The agency requests comments on how it should exercise its authority under section 403(r)(3)(A)(ii) of the act. For example, the agency notes that whole milk will be disqualified from making a claim about calcium and osteoporosis because it contains fat in

an amount that exceeds the disqualifying level. FDA is not proposing to make an exception for whole milk because low fat milk and skim milk could bear such a claim. Thus, the agency believes that there is no basis to make a finding that permitting such a claim on whole milk would assist consumers in maintaining health dietary practices. The agency requests comments on the appropriateness of its approach to this issue. It has been suggested that the agency should consider the net public health benefit in deciding whether to permit a claim on a food that contains a nutrient at a level that exceeds the disqualifying level (e.g., an osteoporosis claim on a food high in fat). This suggestion is that there are advantages in allowing such claims with full and prominent disclosure regarding other nutrients, similar to the requirements for nutrient claims, because the public health gain from consuming the nutrient that is the subject of the health claim would outweigh the risks from consuming the nutrient that would otherwise disqualify the food. A benefit would derive from consuming the nutrient that is the subject of the claim, and a person could balance his or her intake of the disqualifying nutrient by other food selections as part of a total diet. FDA requests comments on this and other approaches in implementing section 403(r)(3)(A)(ii) of the act.

FDA requests comments, including data or other information, on the proposed disqualification levels. If the agency is persuaded by comments that other disqualifying levels, or that modifications in the proposed disqualifying levels, would be more appropriate, FDA will consider making any appropriate changes in the final rule that is based on this proposal.

The agency recognizes that dietary supplements are not subject to the provisions of section 403(r)(3) of the act. However, as explained previously, FDA has tentatively determined that supplements are appropriately subject to the same rules as conventional foods. As a practical matter, however, FDA doubts that disqualifying levels will have any significant impact on supplements because supplements are formulated products that are being promoted as healthful. It would not be logical for such products to be formulated with significant levels of nutrients with known adverse effects.

B. Preliminary Requirements

Congress and FDA, in proposed § 101.14(a)(2), have broadly defined the substances that may be the subject of a health claim. Consequently, FDA anticipates receiving a wide range of petitions for health claims. However, based on the act as a whole, FDA believes that there are certain criteria that must be met before a substance would qualify as the subject of a health claim. The agency is proposing these criteria in § 101.14(b). They reflect not only the requirements of section 403(r) of the act but also the fact that FDA is charged with ensuring the safety of the food supply, and that the food label is not misleading. Given that agency evaluations of the validity of a health claim will be resource intensive, FDA is proposing not to make such an evaluation unless a petition for a health claim demonstrates that the preliminary requirements in proposed § 101.14(b) are met.

1. Effect on General U.S. Population

Section 403(r)(3)(b)(iii) of the act requires that a health claim be stated in a manner "* * * so that the claim enables the public to comprehend the information provided in the claim and to understand the relative significance of such information in the context of a total daily diet." FDA believes that, for this requirement to be satisfied, the general U.S. population or some identified subgroup must be at risk with respect to the particular diet-related diease or condition, or, if that is not the case, the proponent of the health claim and any claim approved by FDA otherwise explains the prevalence of the disease or health-related condition in the U.S. population and the relevance of the claim in the context of the total daily diet. This would permit claims to be evaluated even if no showing was made that any particular population group is currently at risk, but it would require that such information be provided as part of any resulting health claim. In addition, the label or labeling would be required to include any potential risks posed by the nutrient for which the claim is made.

2. Components in Food Within Context of Daily Diet

As stated above, Congress and FDA have provided for a wide variety of food components as potential subjects of health claims. These components range from desirable components, such as essential nutrients, to components whose intake should be limited, such as saturated fat, and even to components that have traditionally served primarily as sources of flavor or aroma, such as herbs.

However, the agency does not believe that Congress intended that everything that can be formulated into a form in which it could be consumed enterally should qualify for health claims. To the contrary, a firm could not add a drug to a food to justify a health claim (e.g., addition of aspirin or an herb whose only known use is for medicinal effects such as belladonna, rauwolfia, or yellow dock). Such addition would make the food a drug within the meaning of section 201(g) of the act. Any substance that is to be the subject of a claim must meet the definition of a "food" under section 201(f) of the act. Consequently, the agency is proposing § 101.14(b)(2) and (b)(3) to assure that claims are made only for substances that are foods.

With respect to what constitutes food, FDA advises that section 201(f) of the act states that the term "food" means "(1) articles used for food or drink for man or other animals, (2) chewing gum, and (3) articles used for components of any other such article." This statutory definition has been interpreted by case law (*Nutrilab, Inc.* v. *Schweiker*, 713 F.2d 335, 338 (7th Cir. 1983)) to include "common sense foods," that is, articles used primarily for taste, aroma, or nutritive value, as well as components of food, both inherent and added.

Consistent with the statute and applicable case law, FDA is proposing in § 101.14(b)(3)(i) that a substance that is the subject of a suggested claim that explains the advantages of consuming the substance at other than decreased levels must contribute taste, aroma, or nutritional value to a food, or serve one or more of the technical effects listed in 21 CFR 170.3(o) (e.g., nutrient supplement). In addition, Congress explicitly directed in section 403(r)(3)(B)(iii) of the act that regulations permitting health claims allow the public to comprehend the significance of the health benefit within the context of the total daily diet so that consumers may modify their diets to achieve public health goals. Obviously a substance must be a food for it to have any significance in the diet.

For consumption of a substance to have significance within the context of the daily diet, FDA is also proposing in § 101.14(b)(3)(i) that the substance must retain its food attributes at the levels that are necessary to justify the claim. For example, if the substance is a vitamin that must be present at a therapeutic level for a health benefit to occur, the supplement would not qualify for a health claim under this proposal. A therapeutic level of a vitamin would be far above that level that is normally characteristic of food, and, consequently, the vitamin would not retain its food attributes. However, FDA is not proposing a specific definition in the general provisions of this proposal

for an upper limit of any substance based on the context of the daily diet. Instead, the agency intends to leave it to the petitions that are submitted to demonstrate on a case-by-case basis that the substance is a food component and is appropriately the subject of a health claim regulation.

FDA is proposing that this provision apply to dietary supplements as well as conventional foods. Section 403 of the act applies to foods, and thus FDA considers it appropriate to require that the substances that are to be the subject of a health claim under the authority of section 403(r)(5)(D) of the act, as well as section 403(r)(3) of the act, satisfy the definition in section 201(f) of the act. This provision is fully consistent with section 411 of the act. The proposed provision places no limits on the potency of safe vitamins and minerals. However, if a claimed effect can only be achieved at a level of a vitamin, mineral, or other substance that scientifically cannot be characterized as nutritional, but rather as therapeutic, then that fact will be considered by the agency in deciding whether the claim is appropriate for a food, or whether it is in fact a claim that would make the product a drug under section 201(g)(1)(B) of the act.

Under proposed § 101.14(b)(3)(i), food components that are modified to such an extent that they no longer retain their food attributes will also not be eligible to be the subject of a health claim. If claims are made for such components, the agency may well regard the components as drugs.

In view of the necessity for a substance to be a food to qualify for a health claim, FDA disagrees with the comments that it has received that asserted that health claims should be permitted for over-the-counter (OTC) drugs. For example, a comment asserted that a manufacturer of a bulk-fiber laxative product that makes the drug claim "relief from constipation" should not be prohibited from making a cholesterol-lowering health claim on the label of that product.

FDA believes that a food claim on a drug product would be misleading to consumers. On a drug label, the thrust of all the information is toward what the product itself will do. For example, the label states that the product will relieve constipation. Moreover, it lists *active* ingredients. Thus, there is reason to believe that in the example cited in the comment, consumers will read the cholesterol-lowering claim as saying that the product itself will lower cholesterol levels, and not that a properly structured diet would have the effect. This interpretation would be wrong, and it is FDA's obligation to try to structure the rules for health claims to minimize the possibility that such misunderstandings will occur. Therefore, FDA believes that it would be inappropriate to put a health claim on a drug product.

Moreover, in a 1934 Senate report for a predecessor bill of the act, there was a discussion on the need for a provision to the effect that the definitions of food, drug, and cosmetic should not be construed to be mutually exclusive (Ref. 15). It was concluded that such language would be superfluous:

> The use of which the product is to be put will determine the category into which it will fall * * *. If it is sold to be used both as a food and for the prevention or treatment of disease it would satisfy both definitions and be subject to the substantive requirements for both. The manufacturer of the article, through his representations in connection with its sale, can determine the use to which the article is to be put. For example, the manufacturer of a laxative which is a medicated candy or chewing gum can bring his product within the definition of drug and escape that of food by representing the article fairly and unequivocally as a drug product. (Ref. 15).

A product that is labeled for relief from constipation has been fairly and unequivocally represented by its manufacturer as a drug. Thus, under this legislative history, the product is subject to regulation only as a drug. As such it would not be eligible to bear a health claim. This is not to suggest, however, that a fiber supplement would not in appropriate circumstances be a food and an appropriate candidate for a health claim. A determination as to whether a claim would be appropriate must be based on the factors proposed in this document and on any specific factors in the regulations in part 101, subpart E.

Further, the comment stated that "dual labeling" of OTC drug products (i.e., drug claims and food health claims in the same labeling) should be permitted to avoid excess proliferation of similar products with different labeling in the marketplace and to be consistent with well-established precedents for dual labeling for drug and cosmetic claims on drug products (e.g., a cosmetic claim, such as "promoting white teeth," and a caries prevention claim for toothpaste).

FDA also rejects this aspect of the comment. The agency believes that the potential for consumer confusion outweighs any concerns about a proliferation of products with health claims. That part of the comment on precedents for drug and cosmetic claims in labeling of the same article is not pertinent to this proposal because of the differences in the substantive requirements for a food health claim compared to those for a cosmetic claim.

3. Safety

As discussed in section IV.A.5 of this document, section 403(r)(3)(A)(ii) of the act states that a health claim may only be made for a food that does not contain any nutrient in an amount that increases to persons in the general population the risk of a disease or health-related condition that is diet related, taking into account the significance of the food in the total daily diet. FDA believes that, in addition to requiring establishment of disqualifying levels, this provision evidences a concern by Congress that a substance that is the subject of a health claim be used in a manner that is safe. This concern was reflected in the statements of the sponsors in both the House and the Senate (Refs. 2 and 3). Further, section 9 of the 1990 amendments states that the amendments "shall not be construed to alter the authority of the Secretary of Health and Human Services * * * under the Federal Food, Drug, and Cosmetic Act * * *." Thus, FDA's responsibility for ensuring the safety of foods has in no way been diminished by the passage of the 1990 amendments.

This fact is particularly significant because the agency will be specifically providing for the health claims that will be made. The agency believes, given its responsibilities under the act, that it would be inappropriate for it to provide for a claim for a substance without assurance that the levels at which the substance will be consumed, or will likely be consumed, in response to the health claim will be safe and in compliance with the food safety provisions of the act.

Accordingly, FDA is proposing in § 101.14(b)(3)(ii) that the substance must be a food ingredient, or a component of a food ingredient, that the proponent of the claim can demonstrate to FDA's satisfaction to be safe and lawful when used at the level that is likely under the claim. This showing can be based on: (1) A demonstration that the substance is generally recognized as safe (GRAS) within the meaning of 21 CFR 170.30; (2) a listing of the substance as GRAS in 21 CFR part 182 or as affirmed as GRAS in 21 CFR part 184; (3) a food additive regulation; or (4) a sanction or approval granted by FDA or the United States Department of Agriculture prior to September 6, 1958. If the safety and lawfulness of the substance is not expressly recognized in an FDA regulation, the burden will rest on the

claims proponent, as a prerequisite to FDA's evaluation of the health claim, to submit all the scientific data and other relevant information required to demonstrate safety and lawfulness in accordance with applicable petition requirements. FDA will withhold review of the health claim until it is satisfied on these points. Given the timeframes that FDA is proposing in response to the act for action on petitions for health claims, the agency anticipates that it may be necessary in many cases to deny the health claim petition without prejudice until the agency has completed its review of the petition for safety of the use of the food ingredient.

By way of explanation, FDA has recognized that it is impracticable to list all substances that are GRAS for their intended use based on their common use in food prior to 1958. For example, FDA regards food ingredients such as salt, pepper, vinegar, and baking powder that were in common use before January 1, 1958, as safe for their intended use. Similarly, § 170.30(d) pertains to food ingredients of natural biological origin that have not been listed by the agency as GRAS and states that such an ingredient will ordinarily be considered to be GRAS if it has been widely consumed for its nutrient properties prior to January 1, 1958, without known detrimental effects, is subject only to conventional processing as practiced prior to January 1, 1958, and no known safety hazard exists. The GRAS ingredients listed in part 182 include manmade ingredients and ingredients of natural origin that were listed in most cases during 1958 through 1962 without a detailed scientific review of all available data and information relating to their safety, and thus their GRAS status is likewise based primarily upon common use in food before January 1, 1958.

In the case of ingredients used in accordance with a food additive regulation, a GRAS affirmation regulation under part 184, or a prior sanction, use of the claim within the provisions of the regulation or sanction will ensure that the ingredient is used under conditions found by the agency to be safe, particularly in the case of food additives and substances affirmed as GRAS because these two classes of ingredients have been subjected to extensive safety review by the agency.

The agency recognizes that health claims are likely to have a significant impact on the level of total consumption of food substances within the U.S. population (e.g., where the total number of foods consumed containing the substance increases without the level of use of the substance within those foods increasing). FDA intends to monitor such consequences closely. To assure that safety is not compromised by changes in consumption patterns, FDA intends to consider whether existing GRAS and food additive regulations need to be revised to adequately ensure the safety of the food supply.

For example, the agency is concerned about the changing consumption patterns associated with the development and introduction into the marketplace of new sources of dietary fiber, along with the increased use of fiber sources as food ingredients or as supplements of fiber, that has occurred in recent years and that could be exacerbated if a claim is ultimately authorized for fiber. FDA intends to update its GRAS regulations for sources of fiber in the near future. To deal with this issue, the agency intends to initiate a review of the existing types of isolated dietary fibers and their use as a broad class of foods to identify and assess scientific information on the safety of this use. This review will include consideration of the biological effects of different fibers, the extent to which such effects are significantly different for subclasses of dietary fiber, and whether biological effects are significantly altered by chemical or physical changes and by processing. FDA may use the results of this or other reviews to develop a new strategy for assessing food safety.

Because sections 201(s) and 409 of the act apply to substances that become components of food by virtue of their intended use, and not to naturally occurring components of food such as cholesterol, these statutory provisions do not apply in instances in which the substance for which a claim is made is a nutrient identified in section 403(q)(1)(C) or (D) of the act that is a component of a whole food (not a food ingredient). However, the previously discussed disqualifying levels proposed under authority of section 403(r)(3)(A)(ii) of the act should provide an appropriate measure of safety for these substances.

C. Validity Requirements

1. The Scientific Standard

FDA is proposing in § 101.14(c) that health claims for all substances, including vitamins, minerals, herbs, and other similar nutritional substances in dietary supplements, be required to meet the following scientific standard:

> FDA will promulgate regulations authorizing a health claim only when it determines, based on the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

This standard embodies the language in the statutory requirements for conventional food in section 403(r)(3)(B)(i) of the act that there be significant scientific agreement about the support for the claim and the mandate provided in the legislative history of the 1990 amendments that FDA have "a high level of comfort that the claim is valid" (Ref. 1).

As Congress recognized (Ref. 1), this standard has essentially the same content as the standard proposed by the agency in the 1990 reproposal. Some of the comments about the appropriate content of the standard favored it as proposed. However, other comments objected to the standard or suggested modifications. Some of these comments expressed concern about the provision of the standard concerning "the *totality* of publicly available scientific evidence." A few comments asserted that this provision should be deleted because new, unreproduced, or controversial findings might not be considered. Other comments asserted that unpublished research findings, including proprietary data, should be considered in assessing conformity with the standard. Many comments objected to the provision requiring "significant scientific agreement" because of a belief that this provision means "consensus" or "unanimity." Several comments maintained that, instead of "significant scientific agreement," FDA should use a scientific standard encompassing different degrees of certainty for different types of health claims.

There is now no basis under the act for the agency to modify any provisions of the proposed standard. The statute ratifies and adopts this proposed standard (section 403(r)(3)(B)(i) of the act). FDA advises, however, that it will consider under this standard the *totality* of publicly available scientific evidence concerning potential health benefits, including new, unreproduced, or controversial findings. Consistent with the intent of Congress in enacting the 1990 amendments (Ref. 1), FDA will use its discretion to give greater weight to those studies that are more persuasive, regardless of the nature or age of the studies.

The agency cannot delete the provision in the standard for the evaluation of validity to be based upon publicly available scientific evidence

because this provision is a requirement of the act (section 403(r)(3)(B)(i)). Any interested party may submit information that is not publicly available in support of a proposed health claim. However, the agency will make all information that is submitted to support a health claim publicly available through its Dockets Management Branch (address above).

In addition, Congress stated that while the studies relied on to support a claim need not necessarily be published in peer reviewed journals, the agency may look to publication as a factor in evaluating the weight to be given the study (Ref. 1). The agency also cannot revise the requirement for "significant scientific agreement" because this requirement is also now a provision of the act. However this provision does not require a "consensus" or "unanimity" of scientific opinion. The requirements of this provision are explained in the legislative history of the 1990 amendments. The House Report (Ref. 1) states:

> The standard is intended to be a strong one. The bill requires that the Secretary have a high level of confidence that the claim is valid. However, the standard does not require a unanimous agreement among experts. Instead, the standard requires that there must be a significant agreement among experts, but it does not require that every expert in the field approve or agree with the claim.
> (H. Rept. 301–538, 101st Cong., 2d sess., 19).

For dietary supplements of vitamins, minerals, herbs, and other similar nutritional substances, the agency has the discretion to propose different requirements for a scientific standard. However, for reasons explained above in section III.D. of this document, FDA is proposing the same standard.

FDA has applied the standard in proposed § 101.14(c) in reading its tentative determinations on the 10 substance-disease topics that are addressed elsewhere in this issue of the **Federal Register.**

2. Assessment of Conformity With the Standard

FDA is proposing no specific provisions pertaining to the agency's assessment of conformity with the standard. However, FDA envisions that to satisfy the scientific standard, a health claim must be supported by a sound body of scientific evidence that establishes the relationship between a substance and a particular disease or health related condition. The data must persuade FDA that the proposed claim is valid, and that the benefits featured in the claim pertain to the general U.S. population or to a significant segment of the U.S. population. Thus, the body of scientific data must be strong. A few unconfirmed studies, incompletely documented data, or significantly contradictory findings do not constitute a sound body of evidence.

Further, the standard also requires that significant agreement exist among qualified experts that the claim is valid. "Qualified experts" include individuals whose training and experience have produced a general or specific scientific expertise in the diet/health topic being considered for a specific claim. FDA is not proposing to define "significant agreement" among these experts because each situation may differ with the nature of the claimed health benefit. The agency believes that any specific definition of such agreement might prove arbitrary when viewed in light of the multiplicity of potential health benefits and the widely variable nature of expertise required to evaluate the significance of these benefits. Instead, FDA intends to use the discretion granted it by the 1990 amendments to assess the degree of agreement on a case-by-case basis. Nevertheless, FDA will take into account the full range of opinions among qualified scientific experts on a specific claim in determining whether significant agreement exists.

FDA is not prescribing a specific set, type, or number of studies as being sufficient to support a health claim. The agency will consider all relevant data on a topic, including clinical studies (human studies conducted in a controlled clinical setting), epidemiological data (data from uncontrolled human populations), and animal studies. However, the type, quality, and relevance of a study from which data are derived have an important bearing on how much weight is placed upon the data. A full discussion of how to evaluate all types of studies on the impact of intake of a dietary substance on health is contained in chapter two of "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 6). Important aspects from that reference provide part of the basis for the following discussion of how the agency intends to evaluate the quality of a study supporting a health claim. FDA requests comments on this approach.

FDA believes that, for human studies, data relied upon must be generalizable to, and preferably obtained from, the U.S. population. FDA intends to give the greatest weight in its evaluation to well designed studies conducted with human subjects and in conformity with the agency's requirements regarding institutional review (21 CFR part 56) and informed consent (21 CFR part 50). Data from laboratory studies using animals, in vitro tests, and chemical analyses of the food substance will also frequently be required to understand the nature of the relationship between the substance and the disease or health related condition. If nonclinical studies (animal or in vitro laboratory studies) are to be considered, those conducted in conformity with the good laboratory practice provisions in 21 CFR part 58 will be given greater weight.

Among human studies, certain types of designs may carry greater weight in demonstrating the purported substance-to-disease relationship. Ecological studies (correlational studies using grouped population data) of diet-disease relationships relate dietary patterns of whole populations to disease incidence or mortality rates for whole populations. Because these studies do not examine the relationship between diet and disease among individuals, the studies have been traditionally regarded as useful for generating, rather than definitively testing, a scientific hypothesis (i .e., an unproved theory). Such studies are descriptive in nature rather than analytical. Thus, the results of ecological studies would be insufficient to demonstrate a relationship without other types of data to support them.

Analytical epidemiology studies (controlled studies on human populations) include case-control studies and cohort studies. In case-control studies, the relationship of a substance to a disease would be examined retrospectively by comparing persons with the disease to persons without the disease as to their exposure to the substance. Cohort studies, on the other hand, observe prospectively individuals who have been exposed to the substance, and those who have not, to determine if disease develops over time. Case-control studies provide less reliable estimates of the strength of associations than cohort studies because they are subject to bias in the detection and selection of cases and to bias in assessing exposure. Also, case-control studies require careful consideration of the validity of dietary data and of the appropriateness of control groups.

An intervention study is a type of cohort study in which the "exposure," or substance under study, is administered, or controlled, by the study investigators and the subjects for disease occurrence. For example, the study investigators may select a group of people to undergo a life-style modification, such as cessation of smoking, whereas an

additional group would make no changes. Both groups would then be followed over time, and their incidence of disease compared. The study investigators would have more control over an intervention study than a routine prospective cohort study because they can randomly select individuals for each group, thereby controlling for attributes other than the one under study that may affect disease occurrence.

Although intervention studies are the most reliable of epidemiology studies for determining cause-and-effect relationships, FDA recognizes that generalizing from selected populations often presents serious problems in the interpretation of such studies. Furthermore, in some cases, such as with cancers of different sites, intervention dietary studies are not feasible because diseases with lower frequency of occurrence, such as rare forms of cancer, require very large study samples to detect an effect. Moreover, there frequently are long latency periods from dietary exposure to onset of disease, often 20 to 30 years.

In evaluating proposed claims, FDA will take into account the feasibility of obtaining what might be considered to be the best evidence and will weigh issues of feasibility against the scientific merits of available studies. In some situations, scientific or ethical conditions may exist that would preclude the acquisition of data from human studies. Such scientific conditions associated with human research include the length of time needed to show an effect (e.g., years versus months), the ability to measure specific indicators (e.g., tissue samples), and the numbers of subjects required to show an effect. Ethical conditions would include potential risks associated with human studies in situations in which the study design would require removal of an individual from known beneficial treatment for the disease or would have an unreasonable, potentially detrimental impact on control subjects. Consequently, the agency would give data from uncontrolled studies greater consideration when either scientific or ethical conditions prevent more controlled studies.

A combination of various types of studies can frequently compensate for deficiencies in individual studies and thus provide a stronger case to prove or disprove a hypothesis. Where FDA evaluates a meta-analysis (i.e., a reanalysis of pooled data from several distinct human studies), the agency considers such an analysis primarily as supporting evidence, rather than as primary evidence, that can confirm the validity of data concerning a health claim. The agency must carefully scrutinize each meta-analysis to assess the soundness of its design and the quality of the data from individual studies to determine the significance of the data. Such scrutiny requires review of copies of all the original studies used for the meta-analysis.

Data from animal laboratory studies, in vitro tests (tests in an artificial environment outside the living organism), and chemical analyses of the substance are particularly valuable in providing information on mechanism of action and pathogenesis (the development of a diseased or morbid condition) to help in understanding the nature of the relationship between the substance and disease or health-related condition. Experiments in different animal species can examine genetic variability and can permit more intensive observation under controlled conditions than can human studies. However, extrapolation of data from animal studies to humans is limited by the comparability of physiologic and metabolic parameters between animals and humans.

The consistency of the demonstrated association between a substance and the disease or health-related condition is important when considering whether evidence from animal studies supports a health claim. Thus, the strongest animal evidence would be based on data derived from studies on more than one animal species or test system, on data that have been reproduced in different laboratories, and on data that give a statistically significant dose-response relationship.

In assessing the overall data in each topic area, FDA will apply these general considerations but will seek to avoid the pitfalls of inflexible adherence to rigidly defined criteria. The overriding principle will be to determine whether there are consistent results from different types of well-conducted human studies by different investigators in different populations. The strengths and weaknesses of each individual study will be evaluated. When experiments with animal models are appropriate, consistency of results between human and animal studies will also be considered. Such results will be interpreted in the light of any available evidence on the biological mechanism of the substance-disease relationship, evidence of a dose-response relationship, and similarity of the test substance with the nutrient or food component of interest. The significance of the disease from a U.S. public health standpoint will also be evaluated. In sum, FDA intends that its judgments concerning the overall quality of available data, the appropriateness of the study design, the consistency across different types of studies and laboratories, and the conclusions derived from the total body of evidence will be based on those generally recognized scientific procedures and principles that are most appropriate to the issues being addressed.

3. Use of Scientific Summaries

A number of comments on the 1990 reproposal addressed the concept of development of a scientific summary as part of the procedure for regulating health claims. However, FDA no longer intends to use a separate document called a "Scientific Summary." The 1990 amendments require that health claim decisions be made by regulation. The agency will discuss the scientific information substantiating the substance/disease relationship in the **Federal Register** document that proposes a regulation for the health claim. The regulation itself will include a summary of the scientific information and the conclusions supported by the science. Therefore, there is no longer a need for the Scientific Summary document.

The 1990 amendments resolve many other issues raised in the comments. The request that scientific summaries be developed in an open process is met by the rulemaking process for establishing regulations. There is opportunity for public comment on the agency's proposed analysis of the scientific information and conclusions. The petitions process that FDA is proposing in response to the 1990 amendments provides the opportunity requested by some comments for manufacturers to develop a scientific summary for the agency's evaluation.

One comment questioned the agency's ability to keep a health claim scientific summary current with the evolution of new data and information on the subject of the summary.

This point is well taken and indicates a need for the agency and the food industry to be mindful of new scientific information on the association between a substance and disease or health-related condition for which a claim is permitted by regulation. The likelihood of a need for frequent revision of any health claim regulation is greatly diminished, however, by the requirements of the statutory standard. The statute requires that, for each health claim, there be significant agreement among experts qualified by training and

experience that the claim is supported by a sound body of substantive scientific evidence. Accordingly, the likelihood of a regulation for a claim rapidly becoming obsolete is small, although not nonexistent. While resource limitations make it impossible for FDA to commit that it will ensure that its health claim regulations will reflect significant developments, any person who concludes that a revision is appropriate can request the revision in a petition using the procedures established by this rulemaking.

4. PHS Committee

In the reproposal (55 FR 5176), FDA proposed to establish a Public Health Service (PHS) Committee on Health Messages to serve as an advisory body to FDA on issues relating to the use of food labels to communicate information on the relationship between diet and health. This committee would have played a key role in assessing conformity with the scientific standard.

Although FDA still sees merit in the proposed role of this committee, section 403(r)(4)(A)(i) of the act provides short timeframes for an FDA decision on whether to file a petition for a health claim and on whether to issue a proposed regulation in response to the petition. With such short timeframes, it would be difficult to incorporate the committee into the regular procedures for assessing requested claims. The agency would find it difficult to assess the petition; forward that assessment to the committee; provide a reasonable time for the committee to consider FDA's assessment; reevaluate the agency's assessment, if necessary, in light of the committee's conclusions; and publish a proposed rule in the **Federal Register** within the statutorily required 90 days from the filing of the petition. However, the agency reserves the right to convene a panel of experts from within the Public Health Service of the Department of Health and Human Services (DHHS) to consider particular petitions. When such a panel is convened, selected DHHS Nutrition Policy Board representatives and key FDA and PHS scientists, with expertise in the subject under consideration, will review the suggested claim. These reviews will provide comments to FDA on the science relating to the claim.

Because the committee is not being formally established, the agency is not addressing specific comments concerning the committee. (Comments concerning the committee were mixed. Some comments endorsed the establishment of a committee, while other comments opposed it or suggested modifications in its proposed role or its composition.)

D. General Labeling Requirements

As explained previously in this document, FDA will propose a regulation in part 101, subpart E when the agency determines that a health claim is valid. The first proposed provision of § 101.14(d)(1) sets forth this agency commitment. This provision also advises that FDA will propose to provide for the listing in the nutrition label of a substance about which FDA is authorizing a health claim if no provision for listing the substance exists. FDA believes that such a provision is necessary to ensure that consumers can readily obtain specific information concerning how much of the substance is present in at least those foods on which a claim about the substance appears.

The other provisions of proposed § 101.14(d) contain general labeling requirements for the health claims that the agency provides for by regulation to ensure that consumers are provided with valid and reliable information about the value that ingestion (or reduced ingestion) of the particular substance, as part of a total dietary pattern, may have in affecting certain diet-related diseases or conditions. (Proposals concerning specific health claims in part 101, subpart E that appear elsewhere in this issue of the **Federal Register** list additional requirements for specific health claims on food labels.) The following is a description of the general requirements for health claims and FDA's rationale for them:

1. The Claim Must Be Consistent With the Authorizing Regulation

Proposed § 101.14(d)(2)(i) states that all label or labeling statements about the health benefit that is the subject of the health claim shall be based on, and consistent with, the conclusions set forth in the summary of scientific information and model health claims provided in regulations in part 101, subpart E.

This provision reflects the requirement under section 403(r)(3)(A)(i), that a health claim may only be made if it complies with the regulations issued by the Secretary (and by delegation, FDA). The act establishes fairly detailed requirements for such regulations. Section 403(r)(3)(B)(iii) of the act states that a regulation authorizing a health claim shall require that the claim accurately represent the relationship between a nutrient and a disease or health-related condition and the significance of each such nutrient in affecting such disease or health-related condition. Further, under this section of the act, the claim is to be stated in a manner that enables the public to comprehend the information provided in the claim and to understand the relative significance of such information in the context of a total daily diet.

To facilitate compliance with these requirements, FDA intends to provide in each regulation authorizing a claim a summary of the scientific information on the substance-disease relationship and a model health claim that includes all the required information.

FDA proposed to establish model health claims for each acceptable health claim in the February 1990 reproposal. The model health claims were to serve as examples for acceptable label statements and to provide guidance for manufacturers who chose to use different phrasing in a health claim. The 1990 reproposal stated that the model health claim would include:

(1) A brief capsulized statement (e.g., about 50 words in length) of the relevant conclusions of the appropriate scientific summary;

(2) A statement of the extent to which the food product contains or does not contain the key food component, and how this food product helps the consumer to attain a total dietary pattern or goal associated with reduction in the risk of the relevant chronic disease;

(3) A reference indicating that more complete nutrition/chronic disease information is available from the appropriate consumer health claim summary, and how that summary may be obtained; and

(4) A statement directing the consumer's attention to the nutrition label for further nutrition information.

The above elements for the model health claim are not as comprehensive as the 1990 statutory requirements for a health claim. Much of the information that would provide an understanding of the significance of the claim within the context of the daily diet would have been included in a consumer health claim summary which, under the 1990 reproposal, was not required to be readily available at the point of purchase. However, under the 1990 amendments, the health claim must include all relevant information (see section 403(r)(3)(B)(iii) of the act). The agency will ensure that all model health claims that it prepares, including those on the specific substance disease topics published elsewhere in this issue of the **Federal Register**, will comply with this requirement.

A summary of the comments pertaining to the reproposal's elements for the model health claim follows.

a. Most of the comments on this subject accepted the concept of a model health claim. Many comments, however, focused on the extent to which a claim on a product label or in labeling would be allowed to depart from the model claim. One consumer organization urged that only claims developed by FDA be allowed as health claims on food products. Recommending that deviation from model health claims not be permitted, the comment suggested that allowance could be made for manufacturers to devise their own health claims provided that they are precleared by FDA. Other comments requested that a model health claim serve as an example for a health claim and that it not be prescriptive. Some urged that manufacturers be allowed the flexibility to make changes in a model health claim so as to vary the content of the claim. They contended that after a time, unvarying messages are likely to become unnoticed and, hence, ineffective.

Section 3(b)(1)(A)(vii) of the 1990 amendments, in describing the regulations on health claims to be established by FDA, states that the regulations shall not require a person who proposes to make a claim described in section 403 (r) (1) (B) of the act (health claims) which is in compliance with such regulations to secure the approval of (the agency) before making such claim. This provision prohibits the agency from requiring preclearance of the phrasing of a claim provided the claim meets the criteria established in the regulation.

The principal reason for developing model health claims is to provide examples of health claims that are clear, accurate, and contain all elements that are necessary for consumers to use and understand the claim. Manufacturers may use a model health claim with the assurance that it is consistent with the permissive regulation authorizing the claim. Manufacturers who choose to craft their own version of a claim from a model claim are free to do so under section 3(b)(1)(A)(vii) of the 1990 amendments. However, the claim they use must be fully consistent with all the regulatory requirements for that health claim. If the labeling does not conform to the regulation, the product is subject to regulatory action as a misbranded food and, possibly, as a drug.

b. Several comments stated that the minimum material facts for a health claim, as generally described for the proposed content of a model health claim in the 1990 reproposal, would be too "wordy" to be effective and too extensive to be accommodated on a product label.

FDA recognizes that some model health claims may be "wordy," but the 1990 amendments have imposed new statutory requirements for health claims to ensure that consumers have sufficient information on the label or labeling to permit a fully informed purchasing decision. As explained previously, section 403(r)(3)(B)(iii) of the act requires that the claim for conventional foods be stated in a manner that enables consumers to understand the relationship of the substance to the disease, the significance of the substance in affecting the disease, and the relative significance of the information in the context of the total daily diet. These statutory requirements cannot be ignored even though, in some instances, the requirements may result in "wordy" claims.

Nevertheless, FDA will attempt to craft specific model health claims that are brief but yet include all essential information to meet the requirements of the act. With specific, rather than generalized, model health claims in the documents on the substance-disease topics elsewhere in this issue of the **Federal Register**, the agency will be able to more easily respond to comments on the content of the proposed claims to determine if they can be made less "wordy" while retaining essential information.

c. One comment said that it would be unnecessary to require a statement directing a consumer's attention to the nutrition label because most consumers interested in the nutritional value of a food would be aware of the nutrition label.

The agency agrees that a health claim need not require a statement directing the consumer's attention to the nutrition label for further nutrition information. With the significant changes in the 1990 amendments to expand the use of nutrition information on a food label, and with education activities addressed to consumers about the importance of that information in maintaining healthy dietary practices, an explicit reference in conjunction with a health claim to nutrition information should not be necessary. This position is consistent with the 1990 amendments which do not require a referral statement in conjunction with health claims as they do in section 403(r)(2)(B) of the act for nutrient content claims (but see section 403(r)(3)(A)(ii)).

d. One comment maintained that a model health claim may be inadequate to convey to consumers all that is necessary to understand the claim. The comment suggested that a manufacturer should have the option for providing information related to a health claim in a product or package insert.

As explained previously in this section, the 1990 amendments impose more comprehensive labeling requirements for health claims than FDA proposed for model health claims in the 1990 reproposal. Thus, Congress has ensured that health claims will be adequately informative for consumers to understand the claim. However, the 1990 amendments refer to health claims made in the labeling of a food as well as on the label (21 U.S.C. 343(r)(1)). Consequently, labeling such as a package insert may serve as the means of providing the required information when the label does not contain sufficient space for the complete health claim, so long as the claim is presented in a manner that complies with proposed § 101.14(d)(2)(iv).

Firms may provide information on labeling in addition to that required by FDA that may be helpful to the consumer in obtaining a deeper understanding of the claim. However, any such additional information would need to be truthful and not misleading. Such information would also have to be consistent with the agency's assessment of the scientific information justifying the health claim, as published in **Federal Register** rulemaking proceedings.

2. Claim Shall Describe Only Those Effects Found To Be Substantiated by Evidence

Proposed § 101.14(d)(2)(ii) states that the claim shall be limited to describing the value that ingestion (or reduced ingestion) of a substance, as part of a total dietary pattern, may have on a particular disease or health-related condition.

FDA will evaluate all relevant data when determining whether to authorize a claim on a substance-disease relationship. On finding that a claim is supported by the available evidence, the agency will describe all the effects of ingestion (or reduced ingestion) of a substance on the disease or health-related condition in the regulation authorizing the claim, which will be codified in part 101, subpart E. Proposed § 101.14(d)(2)(ii) limits the effects described in a claim to those that the agency finds are substantiated by the evidence. Any other effect would not have been substantiated, and including such an effect in a claim would be misleading. FDA is proposing this provision under section 403(r)(3)(B)(iii) of the act, which requires that the claim accurately represent the significance of

each substance in affecting the disease or health-related conditions.

3. Claim Shall be Complete, Truthful, and not Misleading

Proposed § 101.14(d)(2)(iii) states that the claim shall be complete, truthful, and not misleading. Where factors other than consumption of the substance affect the health benefit, such factors shall be addressed in the claim.

This criterion is central to the successful implementation of the proposed health claims policy. "Truthful and not misleading" claims are already mandated by section 403(a)(1) of the act, which deems a food misbranded if its labeling is false or misleading in any particular. Labeling claims are also already subject to statutory requirements concerning adequate disclosure of significant information. Under section 201(n) of the act, labeling can be misleading based on what is omitted from, as well as on what appears on, the label. For example, it would be misleading if a claim omitted significant information that is needed to properly interpret the claim. Even though this proposed provision reflects these statutory requirements, FDA believes that it is important to include the provision in the regulations to ensure that manufacturers understand that the claims that they formulate under FDA's regulations must be complete, truthful, and not misleading.

It has been suggested that FDA should allow claims that reflect more preliminary or controversial scientific findings so long as such claims are qualified in a way that appropriately reflects the state of the scientific evidence. For example, under this suggestion, FDA would allow a claim such as "Preliminary data show that diets rich in fiber reduce the risk of heart disease," so long as there is significant scientific agreement that this is in fact what the evidence shows. FDA has significant reservations about these types of claims, however, because of their potential to be misunderstood by consumers and therefore to be misleading. The agency is also concerned that such claims will undercut the credibility of the food label. This concern exists despite the fact that because such claims arguably do not assert a casual relation between diet and diseases they can never by disproved. FDA requests comments on whether it should authorize these types of claims in implementing the health claim provisions of the act.

Related to proposed § 101.14(d)(2)(iii), FDA is proposing to retain § 101.9(i)(1) (redesignated as § 101.9(k)(1)). This regulation states that any claim on a food product that implies that a substance is effective in the cure, mitigation, treatment, or prevention of a disease that is diet related not only makes the product a drug, but is misleading and will render the product a misbranded food. Such claims imply a degree of association between the substance and the disease that is not supportable for any food within the context of a daily diet. The Surgeon General's Report on Nutrition and Health (Ref. 5) points out that, apart from classic disorders resulting from dietary deficiencies of essential nutrients (e.g., pellagra and niacin), it has proved difficult to demonstrate causal associations between specific dietary factors and chronic or other diseases (e.g., dietary fiber and cancer). The report states:

> Development of the major chronic disease conditions—coronary heart disease, stroke, diabetes, or cancer—is affected by multiple genetic, environmental, and behavioral factors among which diet is only one—albeit an important—component. These other factors interact with diet in ways that are not completely understood. In addition, foods themselves are complex; they may contain some factors that promote disease as well as others that are protective. The relationship of dietary fat intake to causation of atherosclerotic heart disease is a prominent example. An excess intake of total fat, if characterized by high saturated fat, is associated with high blood cholesterol levels and therefore an increased risk for coronary heart disease in many populations. A higher proportion of mono- and polyunsaturated fats in relation to saturated fats is associated with lower blood cholesterol levels and, therefore, with a reduced risk for coronary heart disease.
>
> Because of these complexities, definitive scientific proof that specific dietary factors are responsible for specific chronic disease conditions is difficult—and may not be possible—to obtain, given available technology * * *
> (Ref. 5).

4. Claim Shall be Presented in One Place

Proposed § 101.14(d)(2)(iv) requires that all information that is required by the authorizing regulation appear in one place without other intervening material. The entire claim must appear on the label or other labeling. However, this provision contains an exception so that when the entire claim appears on other labeling than the label, the label may bear the statement, "See ____ for information about the relationship between ____ and ____," with the blanks filled in with references to the location of the labeling containing the health claim, the name of the substances, and the disease or health-related condition. This statement may be coupled with the use of the relevant nutrient content claim. Thus, the food label could state: "High in calcium. See side panel for nutrition information. See attached pamphlet for information about the relationship between calcium and osteoporosis."

This provision is proposed under sections 201(n), 403(a), and 403(r)(3)(B)(iii) of the act to ensure that consumers are not misled by the omission of any essential elements of the health claim but at the same time to permit manufacturers to make consumers aware of the claim. Because labels may be too small to accommodate the entire claim in some circumstances, FDA is proposing an exception to the requirement for complete listing. However, the exception is not limited to situations where the label is too small because the agency sees no potential for consumer deception under the proposed provisions.

5. Claim Shall Enable Public To Understand Information Presented

Proposed § 101.14(d)(2)(v) requires that claims enable the public to comprehend the information provided in the claim and to understand the relative significance of such information in the context of a total daily diet.

This provision is a reiteration of the statutory language in part of section 403(r) (3) (B) (iii) of the act. FDA has considered this requirement in developing the content of the proposed model health claims in the proposals to authorize health claims that appear elsewhere in this issue of the **Federal Register**. The model health claims have been written to provide the basis for a consumer to decide whether (and how) the labeled food best fits into his or her diet. Thus, for example, when a substance-disease relationship has more significance for a particular segment of the population than for the general population (e.g., a segment defined by age, sex, race, or other determinant), the agency has tried to reflect that fact in the model claim.

Further, the proposed provision requires that the claim permit the consumer to understand the significance of the information that it provides within the context of the total daily diet. For example, where the level of an increasable nutrient in a food is at the upper range of normal dietary levels, there may be no known benefit from further intake of that nutrient. In such circumstances, consumers should be advised of this fact as part of the claim. The proposed regulation on calcium and osteoporosis that appears elsewhere in this issue of the **Federal Register**, for example, requires that foods that make

a claim on this topic bear a label statement indicating that there is no known benefit from intake of more than 200 percent of the RDI for calcium.

6. Claim Shall Be Made on Foods With Appropriate Levels of the Substance

Unless the authorizing regulation provides otherwise, FDA is proposing in § 101.14(d) (2) (vi) that a claim about the effects of a decreased dietary intake of a substance can be made on any food in which the substance is present at a level that meets the definition for the use of a "low" nutrient content claim for that substance, if such a definition has been established under Part 101, or is present in an amount that is consistent with that specified in the regulation. Such levels are appropriate for this purpose because FDA has sought to define "low" as a level of a substance (nutrient) that will be helpful to individuals in attempting to comply with dietary recommendations. FDA is proposing in separate documents published elsewhere in this issue of the **Federal Register** definitions in part 101, subpart D for the terms "low fat," "low saturated fat," "low cholesterol," and "low sodium."

If a definition for a "low" nutrient content claim does not exist for the substance, in authorizing a claim, the agency will determine the level of the substance that would qualify a food for a health claim. This determination will be based on any relevant dietary recommendations and on the available scientific information on the specific substance/disease relationship. This level will be included in the regulation in part 101, subpart E that authorizes a claim.

To bear a claim that is based on increased dietary intake of a substance, a food must contain that substance in an appropriate form and at a sufficiently high level. FDA is proposing in § 101.14(d) (2) (vii) that to meet this requirement, the food must contain the substance at a level that would meet the definition for a "high" nutrient content claim if such a definition has been established for that substance in part 101, subpart D. If no definition for a "high" nutrient content claim has been established for the substance, then the agency will propose to establish a specific level in the authorizing regulation.

FDA is proposing that a "high" nutrient content claim be defined as 20 percent or more of the RDI or DRV (§ 101.54(b)). Given the fact that nutrients are not ubiquitously distributed in the food supply, the agency believes it is necessary to meet this proposed requirement to ensure that the food carrying a health claim makes a significant contribution to daily intake. For example, since calcium is not ubiquitously distributed in foods, to achieve 100 percent of the RDI, at least five foods containing 20 percent of the RDI would need to be consumed daily. Based on food consumption patterns, this is a reasonable number of servings and could result in a diet that will achieve the level of the nutrient necessary for the claimed benefit.

FDA believes that a claim based on a increased level of a substance in the diet implies that the food contains a level of the food that makes a significant contribution to the daily diet. Thus, if the food fails to comply with proposed § 101.14(d)(2)(vii), its labeling would be misleading and would misbrand the food.

The agency considered alternatives to the criterion that for health claims dealing with decreased or increased dietary intake of a substance, the level of the substance in a food must meet the definition for a "low" or "high" nutrient content claim. It considered whether a food meeting the definition for a "reduced" or "more" nutrient content claim should also be deemed to qualify for a health claim for that nutrient. On the one hand, some have argued that because the claimedbenefits derive from either decreased or increased dietary levels of the substance, any food that would be helpful in achieving those levels should be permitted to bear a claim. For example, the guideline for lowering salt and sodium dietary intake advises consumers to choose foods that are lower in sodium most of the time. On the other hand, others assert that any health claim should be permitted only for those foods that, when incorporated in a daily diet, are fully compatible with public health recommendations for improving dietary practices within the general U.S. population. "Dietary Guidelines for Americans" (Ref. 7), for example, states that diets low in fat, saturated fat, and cholesterol can be attained through appropriate food selection that includes choosing dairy products that are either lowfat or fat-free. Moreover, if a food starts with a high level of a nutrient, it could meet the definition of "reduced" but still contain a large amount of the nutrient (e.g., a reduced-sodium pickle).

The agency has taken these and other factors into account. Because it believes that compliance with dietary recommendations will be facilitated if only foods that conform to the "low" and "high" nutrient content claim definitions, FDA is proposing to require conformity with those definitions in § 101.14(d) (2) (vi) or (d) (2) (vii).

The agency, however, specifically solicits comment on this issue. Its desire is to establish a sound, equitable requirement that will promote public health. The agency requests comment on whether use of claims on foods that meet the definitions of "reduced," "more," or even other comparative claims will be useful to consumers in achieving the efforts that are highlightedby the claim, or whether allowing the claims on such foods will be misleading because the nutrient levels are not low enough, or not high enough, to really contribute to the claimed effect.

7. Nutrition Labeling for Restaurants

Proposed § 101.14(d) (3) requires that a food that bears a health claim be the subject of nutrition labeling in accordance with §§ 101.9 and 101.36.

Under current § 101.9(a), nutrition labeling is required on all products that contain an added vitamin, mineral, or protein or whose label, labeling, or advertising includes any nutrition claim or information. The agency adopted this requirement under sections 403(a) (1), 201(n), and 701(a) of the act (21 U.S.C. 303(a), 321(n), and 371(a)). Under section 403 (a) (1) of the act, a food is misbranded if its label or labeling is false or misleading in any particular. Under section 201(n) of the act, the label or labeling of a food is misleading if it fails to reveal facts that are material in light of representations actually made in the label or labeling. Finally, under section 701(a) of the act, the agency has authority to issue regulations for the efficient enforcement of the act.

The applicability of current regulations to restaurant foods was discussed in rulemaking promulgating § 101.10 *Nutrition labeling of restaurant foods* (21 CFR 101.10) (39 FR 42375, December 5, 1974 and 41 FR 51002, November 19, 1976). In the preamble to the proposed rule, the agency discussed its belief that nutrition education is of prime importance and stated that it will take every opportunity to foster the dissemination of such information to the consumer, including the use of nutrition labeling in restaurants. However, the agency acknowledged that if nutrition information provided in restaurants necessitates the expense of nutrition labeling, the restaurant "may choose not to provide any nutrition information in advertising or labeling, on the basis that the added cost of providing detailed information might cause the project of providing nutrition information not to be worth the expense" (39 FR 42375). Therefore, to encourage the dissemination of nutrition information in

the food service industry, FDA proposed to exempt ready-to-eat foods from the requirement of bearing nutrition labeling on food labels if the required nutrition labeling was displayed prominently on the premises by other means, e.g., counter cards or wall posters, where the information would be readily available to the consumer when he is making a menu selection.

Subsequent action on this proposal led to the issuance of a statement of policy in § 3.207 (recodified as 21 CFR 101.10 in the **Federal Register** of March 15, 1977 (42 FR 14302)) that if any advertising or labeling (other than labels) includes a claim or information about the total nutritional value of a combination of two or more foods (e.g., a combination consisting of a hamburger, french fries, and milkshake), then, as an alternative to providing nutrition information about each separate food on the food label, the restaurant may instead provide information about the total nutritional value of the combination of foods, provided that the statement of total nutritional value follows the nutrition labeling format and provided that the nutrition information is effectively displayed to the consumer both when he/she orders the food, and when he/she consumes the food.

As discussed in the supplementary nutrition labeling proposal published elsewhere in this issue of the **Federal Register**, the 1990 amendments specifically exclude restaurant foods from the requirement for nutrition labeling. However, as stated above, the agency believes that it has the authority to issue regulations requiring restaurants that choose to make health claims to adhere to the requirements for such claims, including nutrition labeling.

FDA is not, at this time, making any specific provisions for the nutrition labeling of restaurant foods. FDA specifically seeks comment on how it should handle this issue. On one hand, many believe that it is important that consumers be given useful and meaningful nutrition information. On the other hand, many continue to be concerned, as FDA was in 1974, that the cost of compliance not be so high that restaurants will not be willing to offer and identify through health claims those foods that will assist consumers in selecting diets that provide health benefits. Therefore, the agency is requesting comments on whether and to what extent it has a basis for nutrition labeling when health claims are made on restaurant foods, or whether a requirement for such labeling would discourage restaurants from making health claims because of the cost associated with nutrition labeling.

If, based on comments received, FDA were to require nutrition labeling of restaurant foods, should the requirement apply only to large restaurant chains with fixed menu items? Additionally, should the content or format of nutrition labeling be different for the food service industry than for packaged foods? If so, how and why?

FDA recognized in its July 19, 1990 (55 FR 29487 at 29504), reproposal on mandatory nutrition labeling that certain restaurant-type food service facilities cannot reasonably be expected to provide information concerning nutrient profiles, and that exemptive provisions should be established for such situations. The proposal advised that comments pointed out that nutrition labeling for foods served in restaurant-type facilities present significant feasibility problems in a number of situations. The comments made the following points: These facilities may not be able to develop consistent nutrient information on the foods that they sell because of frequent menu changes and variations in how the consumer wants the food prepared and served. Without nutrient consistency, frequent nutrient analyses would have to be performed to provide consumers with accurate nutrition labeling information. These analyses could become very burdensome. The cumulative costs of these analyses could place undue restrictions on some establishments. Firms could be inhibited from making frequent menu changes or forced to I imit the options that consumers have in ordering a food.

Because of these problems, FDA proposed an exemption under section 201(n), 403(a), and 701(a) of the act for restaurant-type foods in the mandatory nutrition labeling proposal (see proposed § 101.9(h) (2), SSFR 29516). Although the agency wanted to limit the exemptions to only those situations in which it is needed, FDA did not, and still does not, have sufficient indepth knowledge of the food service industry to develop adequate criteria to fairly impose such limitation. The agency therefore requests comments on this issue.

A related question is what to be done with § 101.10. Because § 101.10 was adopted under section 403(a) of the act, it is not subject to state enforcement under section 307. For this reason, and because § 101.10 has not been enforced by FDA, the agency believes that it is appropriate to make an affirmative statement about the cont.inuing need for this provision. Thus, if FDA elects not to make restaurant labeling part of the NLEA implementation, the agency will, in the final rule, delete § 101.10.

8. Dietary Supplements

Because the provisions in § 101.14(d) derive in large part from section 403(r) (3) of the act, an argument can be made that they should not apply to dietary supplements. However, FDA believes that these provisions are necessary to ensure that claims are not misleading, are valid, and are useful to consumers. Therefore, FDA is proposing to adopt these provisions for dietary supplements based on its authority under section 403 (r) (5) (D) of the act to ensure the validity of claims on these foods.

E. Prohibited Claims

1. Claims not Authorized by FDA

Proposed § 101.14(e) (1) and (e) (2) prohibit on a food label or in labeling any claim that expressly or by implication characterizes the relationship of any substance to a disease or health-related condition unless: (1) The claim is a health claim specifically provided for in part 101, subpart E; and (2) the claim conforms to all general provisions of this section as well as to all specific provisions in the appropriate section of part 101, subpart E.

Although the nature of the proposed prohibition may be obvious for explicit claims (e.g., products bearing statements about cholesterol-lowering effects are explicit claims about a health-related condition) because of their forthright nature, the nature of the prohibition is not as obvious for implied claims. Proposed § 101.14 (a) (1) points out that implied claims include a wide variety of forms of expression, including "third party" endorsements, written statements (e.g., a brand name including a term such as "heart"), -symbols (e.g., a heart symbol), and vignettes.

With respect to "third party" endorsements of food, FDA considers this term to refer generally to any type of approval or implied support for the food pertaining to disease or health-related matters, with or without product specific information, by a person or organization that is independent of the product's manufacturer or distributor. When the endorsement is from a professional society or association that has been identified with treatment of a specific disease, consumers may be led to believe that the food may be useful with respect to the disease. Even when the endorsement is not product specific, there is a potential for consumer deception where consumers may be

given a false sense of security that consumption of products that bear labeling references to the organization or the organization's logo or seal will protect them from the disease.

Examples of some of the types of labeling endorsement programs that FDA has considered to be implied health claims include programs that have been sponsored by the American College of Nutrition, the American Heart Association, The American Medical Association ("Campaign Against Cholesterol"), and the American Medical Women's Association. The agency recognizes, however, that professional societies and associations provide a unique service in establishing criteria for assessing diets of both healthy population groups as well as those who require modifications or restrictions in their diets. FDA encourages such organizations to collaborate with the agency in the development of its regulations pertaining to health claims through submission of specific comments on this proposal as well as on the specific proposals on the 10 substance-disease topics that are published elsewhere in this issue of the **Federal Register.** The agency requests comments on whether it should consider all third-party endorsements that imply that a nutrient in a food has an effect on a disease or health-related condition to be health claims, or whether there are some limits on FDA's coverage of third party endorsements that should appropriately be drawn?

Where other Federal agencies have established programs to change dietary patterns to reduce the risk of diet-related diseases (e.g., the National Cholesterol Education Program), FDA recognizes that references to such programs on food labeling may also be perceived by consumers as "third party" endorsements. Although FDA is proposing to regulate labeling references to such Federal programs as implied health claims, the agency believes that the benefits of these programs to consumers may be significant if the labeling messages that are conveyed to consumers about the other Federal programs are properly merged with the specific health claims that are provided for under part 101, subpart E. Without appropriate merging of information about health benefits, consumers could, however, be confused about the significance of the benefits.

FDA believes that the most efficient way to ensure that consumers will not be confused about this significance is to establish, by regulation, the specific types of statements that may be made on food labeling concerning the Federal programs. The agency is requesting that comments concerning what statements about Federal programs would be appropriate on food labeling be submitted for the appropriate specific regulations in part 101, subpart E. Based on these comments, FDA intends to include a listing of the statements that may be used in the final rules on these regulations. FDA advises interested parties that, at this time, the agency believes that labeling references to the programs should not be made through logos because such visual representations may have too wide a variety of meanings to consumers.

A second, related question with respect to implied health claims is how to regulate the use of symbols such as a heart or electrocardiogram. The agency is aware that symbols are particularly useful in conveying information in a simple and efficient manner. Research has demonstrated that heart symbols, for example, on food labeling are perceived by consumers as meaning that the food has special usefulness relative to health and especially with regard to coronary heart or cardiovascular disease (Refs. 22 and 23). FDA has also heard from consumers, however, that symbols have been used in misleading ways.

The threshold problem with symbols is how to regulate them under the scheme established by the 1990 amendments. On the one hand, properly qualified by other statements on the food label, a heart symbol, for example, can be used as an implied nutrient content claim to denote a food that is low in fat, saturated fat, sodium, and cholesterol. On the other hand, as stated above, a heart that is not qualified by other statements on the label would arguably represent a health claim that a nutrient in the food has some special role in promoting coronary or cardiovascular health.

FDA invites comments on the regulatory approach that it should take to symbols for use on the food label.

FDA does not agree with comments that have suggested that statements identifying certain dietary components (e.g., fiber, calcium) constitute implied health claims, even when the label avoids directly mentioning a disease. Such claims are specifically regulated as nutrient content claims under section 403(r)(1)(A) of the act and are addressed in the agency's proposal on nutrient content claims published elsewhere in this issue of the **Federal Register**. After the effective date of the 1990 amendments, such claims are prohibited unless FDA has issued a regulation defining the particular claim.

2. Disqualifying Levels Exceeded

Proposed § 101.14(e) (3) requires that none of the disqualifying levels identified in paragraph (a) (5) of this section be exceeded in a food that bears a health claim, unless specific alternative levels have been established for the substance in part 101, subpart E, or unless FDA has by regulation permitted such a claim based on a finding that such a claim will assist consumers in maintaining healthy dietary practices. If FDA makes such an exception, the label of the food would have to bear a statement in immediate proximity to the claim that refers the consumer to the nutrition label for information about the nutrient that exceeds the disqualifying level. This statement must be made in a manner that complies with proposed § 101.13 (h). FDA is proposing this provision under the authority of section 403(r)(3)(A)(ii) of the act.

A complete discussion of the disqualifying levels was presented previously in section IV.A.5 of this document.

3. Inappropriate Levels of Other Substances

Proposed § 101.14(e)(4) prohibits claims for any food where a substance, other than one for which a "disqualifying level" is established, is present at an inappropriate level as determined in specific provisions of part 101, subpart E.

This provision implements a number of different provisions of the 1990 amendments. As was stated previously in this document, section 403(r)(3)(A)(ii) of the act prohibits a claim where any nutrient is present in an amount that increases the risk of a disease or health-related condition that is diet related to persons in the general population, taking into account the significance of the food in the total daily diet. In section IV.A.5 of this document, the agency advised that two approaches for implementing this provision include the preliminary requirement that use of the substance at relevant levels have been found to be safe under agency regulations, and that the "disqualifying levels" not be exceeded. A third approach, which the agency is also proposing to adopt, is to prohibit claims for foods containing any level of a substance, other than one for which a disqualifying level is established, where that substance increases such risk. This provision proposed in § 101.14(e)(4), is intended, in part, to provide for a situation in which

such a substance, or a level of a substance, is identified in one of the specific regulations in part 101, subpart E. However, at this time the agency is not aware of any such situations.

In addition, this provision is intended to implement other aspects of the 1990 amendments. Proposed §§ 101.14 (d)(2)(vi) and (d)(2)(vii) require that substances be present at a level sufficient and in an appropriate form to justify the claim. Proposed § 101.14(e)(4) supplements paragraphs (d)(2)(vi) and (d)(2)(vii) by providing the basis by which FDA can assure through provisions in specific regulations in part 101, subpart E that the appropriate form of the substance is used in light of levels of other nutrients or food components that may counter the effect of the substance for which the health claim is made. Counter effects may include interference with the substance to reduce its absorption, metabolism, or utilization by the body, thereby reducing or negating the substance's value.

For example, the proposed health claim concerning calcium and osteoporosis, published elsewhere in this issue of the **Federal Register**, contains a provision (proposed § 101.72(c)(5)) providing that a serving or recommended total daily intake of a food shall not contain more phosphorus than calcium on a weight per weight basis. As explained in that proposal, this provision is based primarily on scientific evidence demonstrating that diets high in phosphorus and relatively low in calcium result in osteoporosis in experimental animals.

Similarly, if a health claim were permitted in part 101, subpart E associating increased dietary copper intake with a reduced risk of a disease (although note that no such claim is contemplated at this time), it is conceivable that the interactive effect of dietary zinc intake on copper status would have to be considered to assure that an adequate dietary copper intake is attained for the claimed benefit. The antagonistic effect of high levels of dietary zinc on copper absorption and status has been demonstrated in humans and in a variety of animal species (Ref. 16). Some studies, but not all, have reported subtle negative effects of increased intake of zinc, not much in excess of the Recommended Dietary Allowance (RDA) for zinc, on biological indicators of copper status. For example, a study in men of the effect of zinc intake at 3⅓ times the RDA level reported a decrease in zinc, copper-superoxide dismutase, a red blood cell enzyme that is dependent on copper but not zinc status and that thus serves as an index of tissue copper status (Ref. 17). Accordingly, FDA would prohibit a health claim for copper on a food whose zinc level is above the RDA or RDI level.

4. Representing Food for Infants or Toddlers

Proposed § 101.14(e)(5) provides that no food may bear a health claim if it is represented or purports to be for infants and toddlers less than 2 years of age.

The American Academy of Pediatrics, in their comment to the 1990 reproposal, expressed concern that a health claim directed toward adults may be inappropriate or harmful to infants and young children. One example cited was that the link between lipids and cardiovascular disease is not established in young children as it is in adults. Consequently, though diets high in fats may be undesirable for adults, the comment stated that infants and toddlers must ingest a certain amount of fat for their growth and development. Accordingly, the comment recommended that a health claim for adults should indicate that it is not intended to apply to infants and young children.

Furthermore, both "The Surgeon General's Report on Nutrition and Health" (Ref. 5) and "Diet and Health, Implications for Reducing Chronic Disease Risk" (Ref. 6) state that, because of the increased nutrient demands of children during the early periods of rapid growth and development, the dietary recommendations are not applicable to persons under 2 years of age. The criteria for health claims being proposed in this and the companion documents are based on dietary recommendations for the U.S. population, excluding very young children. Therefore, the agency has tentatively concluded that health claims are inherently misleading if used on the labels of foods represented or purported to be for infants and for toddlers under 2 years of age. Therefore, under sections 201(n), 403(a), and 403(r) of the act, FDA is proposing in § 101.14(e)(5) to prohibit the use of health claims on foods for these young children.

F. Need for Additional Prohibited Claims

FDA is concerned that under these proposed regulations some foods that are inconsistent with generally recognized medical and nutrition principles for a sound total dietary pattern will be permitted to bear health claims. For example, some diet confections, which have no nutritional value, would be permitted to bear health claims for lipids and cardiovascular disease, lipids and cancer, and sodium and hypertension, if the regulations on these substance-disease relationships are finalized as proposed.

Such a situation seems contrary to one of the stated purposes of the health claims provisions of the 1990 amendments—to reinforce Federal dietary recommendations and help Americans maintain a balanced and healthful diet (Ref. 1). This purpose was reinforced through statutory provisions in section 403(r)(3)(A)(ii) of the act requiring FDA to consider the significance of the food in the total daily diet when determining whether a nutrient that increases the risk of a disease or health-related condition should disqualify a food from bearing a health claim. Congress explained (Ref. 1) that this provision "permits the Secretary to differentiate between different foods which have the same level of a nutrient. For example, a particular level of fat in a frozen dinner might not trigger the provision, whereas that same amount of fat in a snack food product might trigger it." Thus, FDA believes that provisions permitting health claims on only foods recognized as within a sound dietary pattern would be consistent with the intent of Congress.

However, FDA is not aware of any way to limit health claims to only those foods within a sound dietary pattern at this time. The agency considered, and decided against, proposing a provision prohibiting claims unless there is consistency with generally recognized medical and nutrition principles for a sound total dietary pattern (e.g., consumption of the food is consistent with the current edition of "Nutrition and Your Health: Dietary Guidelines for Americans," Third Edition, 1990 (Ref. 7), and the food is not a snack food such as candies or those low in essential nutrients.

For the general U.S. population, "Dietary Guidelines for Americans" provides guidelines on the relationship between diet and various diseases and conditions such as obesity, hypertension, cancer, and deficiency diseases. The guidelines reflect the dietary recommendations contained in the "The Surgeon General's Report on Nutrition and Health" (Ref. 5) and "Diet and Health, Implications for Reducing Chronic Disease Risk" (Ref. 6). The guidelines embody dietary principles for consumption of foods with significant nutritional value and for reduction or control of certain food components associated with diet-related diseases or conditions. Throughout FDA's development of both the specific health

claims proposals for part 101, subpart E, as well as the general provisions of this proposal, FDA has considered these guidelines.

At the present time, the guidelines are: Eat a variety of foods; maintain healthy weight; choose a diet low in fat, saturated fat, and cholesterol; choose a diet with plenty of vegetables, fruits, and grain products; use sugars only in moderation; use salt and sodium only in moderation; and if you drink alcoholic beverages, do so in moderation.

However, FDA believes that the guidelines are too general in nature to serve as binding rules upon which the agency can readily take regulatory action. For example, what foods would clearly fit into an appropriate variety of foods? What portion of foods would constitute a moderate amount of sugars? How would the agency define "snack foods?" The agency requests comments from all affected parties concerning what provisions might effectively permit health claims only on foods that can make a significant contribution to a healthful diet. If the comments suggest appropriate provisions, FDA will include them in any final regulation based on this proposal.

G. Exempted Foods

Medical foods, as defined in section 5(b) of the Orphan Drug Act, and infant formulas subject to section 412(h) (21 U.S.C. 350a) of the act are specifically exempted from requirements for health claims and nutrient content claims by section 403(r)(5)(A) of the ac' FDA is proposing to codify these statutory provisions in § 101.14(f).

In addition, section 403(q)(5)(A)(iv) exempts medical foods from nutrition labeling requirements. To deal with this latter exemption, the agency has incorporated the definition of "medical food" in the supplementary proposal on mandatory nutrition labeling, published elsewhere in this issue of the Federal Register, to clarify this definition by providing criteria in proposed § 101.9(j)(7) for use in identifying a medical food. As explained in that proposal, minimum criteria to distinguish a medical food from other foods include: The product must be a food for oral or tube feeding; the product must be labeled for the dietary management of a specific medical disorder, disease, or condition for which there are distinctive nutritional requirements; and the product must be intended for use under medical supervision (Ref. 18).

The supplementary proposal on mandatory nutrition labeling states that medical foods are not foods that are simply recommended by a physician or health care professional as part of an overall diet to reduce the risk of a disease or medical condition or promoted as weight loss products. Nor do medical foods include dietary supplements for the general population that can be openly purchased from retail outlets or by mail order, even though dietary supplements may be recommended by a physician for a specific condition or disease. The intended use and degree of medical oversight for dietary supplements are not regarded to be sufficient to qualify them as medical foods.

FDA is reevaluating its traditional policy to regulate medical foods as foods for special dietary use in light of the existing definition of foods for special dietary use and the definition of medical food enacted by Congress (21 U.S.C. 350(c) and 360ee(b)(3)). FDA intends to address the issue of medical foods in a future Federal Register document.

Infant formulas that are subject to section 412(h) of the act are known as "exempt infant formulas" because they are exempt from the requirements of sections 412(a), (b), and (c) of the act, which pertain to other infant formulas. Instead, exempt infant formulas are subject to regulations established by the Secretary under the authority of section 412(h)(2) of the act. Exempt infant formulas are defined in section 412(h)(1) of the act as any infant formula which is represented and labeled for use by an infant: (1) who has an inborn error of metabolism or a low birth weight, or (2) who otherwise has an unusual medical or dietary problem. Regulatory requirements for exempt infant formulas, including claims, are contained in 21 CFR part 107.

H. Applicability of the Regulation

FDA is reflecting the applicability provisions of section 403(r)(1) of the act in proposed § 101.13(g). This provision states that the requirements of proposed § 101.13 apply to foods for human consumption that are offered for sale. Thus, the proposed health claim regulations apply to foods for human consumption sold in grocery stores and other settings.

I. Other Issues

1. Consumer Summaries

The 1990 reproposal would have required preparation of a consumer summary concerning a health claim on a food label. The summary would have been an extension of the health claim on the label to provide full information about the relationship between the food and the disease about which the claim pertained. The summary was intended to facilitate the consumer's assessment of whether the health claim applied to him or her and, in certain instances, to what extent it applied. The summary was also intended to help alleviate the potential problem of information overload on the label. A summary was to be developed for each diet and chronic disease relationship for which a health claim would be appropriate. The food label bearing the health claim would have been required to reference the summary.

The comments generally focused on the concept of developing the summaries through a process that is open and allows for public comment. Some of the comments expressed interest in the development and testing of the summaries. Other comments expressed concern about the accessibility of consumer information at the point of retail sale.

In view of new statutory requirements for the label or labeling of a food bearing a health claim, FDA believes that consumer summaries may no longer be necessary. Section 403(r)(3)(B)(iii) of the act states that the regulation authorizing a claim shall require that the claim be stated in a manner: (1) That accurately reflects the relationship between the substance and the disease or health-related condition, and the significance of the substance in affecting the disease or health-relate condition, and (2) that enables the public to comprehend the information provided in the claim and understand the relative significance of such information in the context of a total daily diet. This provision requires that the claim present the most significant aspects of the information that the agency was considering to require in the consumer summaries. Therefore, FDA fails to see what purpose a consumer summary would serve and is not proposing to require these summaries at this time.

However, FDA solicits comments on whether consumer health claim summaries can still serve a useful purpose. The agency asks that interested persons examine the specific model health claims proposed elsewhere in this issue of the Federal Register and the consumer summaries that FDA has prepared and consider whether these summaries, which present in lay language, information about the association between the substance and the disease or health-related condition, are needed. If comments persuade the agency that these summaries should in fact still be required, FDA may include a requirement for the summaries in any final rule that is based on this proposal.

The purpose of a consumer summary would be to provide supplementary information to that on the label about substance-disease relationships for consumers who are interested. Such information may include, among other things, a discussion about the disease or health-related condition, its prevalence in the U.S. population, and the relative degree of risk for specific subpopulation groups. In addition, dietary information on other food sources of the claimed nutrient or substance, information on nondietary risk factors for the disease, and other similar information may be provided.

2. Consumer Guide to Food Labeling

The 1990 reproposal would have required the agency to prepare a consumer guide to food labeling (consumer guide) as an adjunct to the procedure for health claims. The consumer guide would have discussed in general terms how the various types of consumer-oriented information found on the food label are to be used. The consumer guide was intended to address questions such as:

(1) What is a consumer health claim summary, and who is it for?

(2) What is nutrition labeling, and how is it used in dietary planning?

(3) What is the importance of the total diet in maintaining good health?

(4) How do dietary supplements best fit into a total daily diet?

(5) What is the process used to develop label statements and consumer health claim summaries?

(6) Are label statements and consumer health claim summaries applicable to specific groups (e.g., certain statements or claims may not be appropriate for children)?

(7) How can consumers use ingredient statements, common or usual names of foods, and nutrient content claims (e.g., low sodium) to assist them in achieving sound dietary practices? FDA conceived of developing one "umbrella" consumer guide that would be broadly applicable to all health claim subject areas.

All comments on the 1990 reproposal endorsed development of the guide. Most of the comments addressed the availability of the consumer guide, stating that it should be widely distributed, accessible, or available. One comment said that information on availability of the consumer guide should be given on the product label. One comment suggested that the consumer guide should be published in the **Federal Register** for public comment before distribution to consumers. Another comment suggested that the consumer guide be developed cooperatively with organizations outside FDA. One consumer organization suggested that the consumer guide should be distributed to beneficiaries of public assistance programs to assure that persons with low incomes have access to nutrition information. Another recommendation was that, in addition to English, the guide should be published in other languages.

Although FDA still intends to issue a consumer guide, the agency believes that such a consumer guide should be issued separately from this proposal. Section 2(c) of the 1990 amendments directs FDA to carry out activities that educate consumers about the availability of nutrition information on the label and in labeling of a food and about the importance of such information in maintaining healthy dietary practices. Inclusion of the consumer guide on health claims as a part of these new educational activities will address the issues and concerns that motivated FDA to propose the consumer guide.

Accordingly, FDA believes that it is not necessary for it to respond more specifically to the comments about the consumer guide at this time. Of course, the agency will consider these comments when a guide or other educational material is being prepared.

J. Petitions for Health Claims

Section 403(r)(4)(A)(i) of the act grants any person the right to petition the agency to issue a regulation authorizing a health claim on a substance-disease relationship. Section 403(r)(4)(B) of the act requires that the petition include an explanation of the reasons why the claim that is the subject of the petition meets the requirements of section 403(r) of the act and a summary of the scientific data that support those reasons. The act also states that if the petition relies on a report from an authoritative scientific body of the United States, the agency shall give particular consideration to such report and shall justify any decision rejecting the conclusions of such report (section 403(r)(4)(C) of the act)

The act requires in section 403(r)(4)(A)(i) that, within 100 days of receipt of a petition for a regulation concerning a health claim, FDA must either issue a final decision denying the petition or file the petition for further action. If the agency denies the petition, it is not made available to the public. If FDA files the petition for further action, the agency must either deny it or publish a proposed regulation responsive to the petition within 90 days of filing.

However, the foregoing provisions do not apply to health claims for dietary supplements. Under section 403(r)(5)(D) of the act, as stated above, these claims are subject to a procedure established by regulation by the Secretary of Health and Human Services (and by delegation, FDA).

On March 14, 1991, the agency published a notice in the **Federal Register** (56 FR 10906) that it is developing procedural regulations that will prescribe the types of information needed to support petitions for health claims and the other types of petitions permitted by the 1990 amendments (including petitions concerning nutrient content claims and State petitions for exemption from Federal preemption granted by the 1990 amendments), the format in which the petitions are to be submitted to the agency, and the procedures that the agency will follow in its review of these petitions. The agency requested comments on these issues and on the following:

(1) Criteria that should be used in evaluating health claim petitions;

(2) The extent, manner, and timing that the agency should use to give public notice of petitions; and

(3) The appropriate procedure for establishing regulations on permissible health claims for dietary supplements.

The agency stated that the most efficient use of its resources would be to establish these procedures in final form before considering, or acting on, any such petitions that are submitted to the agency. The agency, therefore, advised that it would likely deny any petition submitted under the 1990 amendments until final procedural regulations are promulgated.

FDA received comments pertaining to petitions for health claims from the food industry, industry trade associations, and consumer organizations. FDA considered the comments, and many of the recommendations contained therein have been incorporated in, or otherwise used in, the development of this section of the proposed rule.

1. Comments

Some comments objected to the requirement for "publicly available evidence" and stated that unpublished research findings, including proprietary data, should be considered in support of proposed health claims. These comments further stated that firms will be able to justify undertaking research and development activities relating to diet/health relationships only if the regulatory framework allows them to recapture, through competitive marketing, some of the expense of research. They stated that, if regulations are adopted requiring that results be made public to substantiate a health

claim, then this substantiation could be used by other companies to make similar claims. The comments pointed out that the original petitioner would lose its competitive edge and thereby its motivation to perform research. Comments also suggested that the petition process should provide for the strictest confidence in the submission and maintenance of proprietary, unpublished studies.

The agency advises that section 403(r)(3)(B)(i) of the act mandates that "publicly available evidence" be used to support the scientific standard for health claims. Moreover, section 403(r)(A)(i) provides for not making a petition available to the public only if FDA decides to deny it without filing it. Consequently, FDA does not have authority to provide the relief the comments seek. The agency will make all information submitted in support of a health claim publicly available when the petition is filed and thus becomes available to the public.

An approved health claim is a description of a substance-disease relationship. It is not brand specific and, therefore, may appropriately be used by any firm whose food product meets the criteria for the claim.

Another comment stated that, in the past, in evaluating substance-disease relationships, the agency has placed too much reliance on findings published in a few peer-reviewed journals, and that the language in section 403(r)(3)(B) of the act; "totality of publicly available scientific evidence," should not be construed to limit evaluation to such reports. Other comments recommended that petitions should be accompanied by extensive literature reviews and include copies of all animal studies and human epidemiological or clinical trials relevant to the proposed health claim.

The agency advises that under proposed § 101.70(f) the petitioner is required to submit copies of all information, published or unpublished, relied upon for the support of the health claim, as well as information related to the claim that concerns adverse effects in individuals. Further, the petitioner must also submit copies of all information relevant to the claim that is pertinent to the U.S. population. The agency is, therefore, proposing to require that a broad array of information be submitted with the petition. Consequently, the agency's review of the proposed topic will not be limited to peer-reviewed publications, although, as suggested in the legislative history (Ref. 1), the agency may give greater weight to a research report published in a peer-reviewed journal because such reports have been subjected to scientific evaluation before publication. The agency intends to give greatest weight, however, to research reports of well-conducted, relevant studies regardless of publication status.

To ensure that submitted information is not biased, one comment recommended that the petition include an assurance statement, such as that required in petitions for the affirmation of the GRAS status of a substance (§ 170.35(c)(1)(v)), whereby the petitioner certifies that the petition contains all favorable and unfavorable scientific data of which he has knowledge. The agency agrees that this requirement is appropriate for a petition that must draw upon the totality of publicly available scientific evidence to support the proposed health claim, and this requirement has been included in the proposed procedural regulations in § 101.70(h).

Several comments addressed format issues for health claims petitions. One comment stated that the format for submission of citizen petitions (§ 10.30) is applicable to health claims petitions.

FDA recognizes the point made in these comments but tentatively concludes that, given the provisions of section 403(r) of the act, it is appropriate to specifically describe the information that should be submitted in support of a health claims petition in a regulation that is separate from § 10.30. The agency believes that a procedural regulation for a health claims petition is necessary so that petitioners will clearly understand what is required, that review will be conducted on an equitable basis, and that the grounds for agency action on the petition will be clearly understood.

A comment stated that the proposed regulations should provide that, for well-substantiated petitions setting forth substance-disease relationships that are widely accepted in the scientific community, the initial agency response time should be reduced from 100 to 60 days, and the agency's proposed regulation should be published within 30 rather than 90 days after the initial response.

The agency's ability to meet timeframes is influenced by many factors such as work priorities and availability of personnel. FDA considers the statutory timeframes for assessing the validity of health claims to be extremely short for evaluating the totality of available scientific evidence on a substance and a disease. It would not be practicable to shorten these timeframes further. The agency does agree that a petition for a claim on a well accepted diet/health relationship would probably be reviewed more expeditiously than one for which scientific agreement is equivocal or marginal.

Several comments recommended procedures for the evaluation of health claim petitions. One recommended the development of a multifactorial scoring system to be used to evaluate health impact based on the product's total nutrient content, the level of nationwide consumption, and the scientific validity of the health claim. This system would incorporate a cut-off limit to determine whether a petition is acceptable. Another suggested criterion was that the new health claim be recognized by reputable health organizations or research centers.

As discussed in section IV.C. of this document, the extremely short timeframes provided under the act for FDA to decide if a health claim is to be authorized make significant input from other health organizations impracticable before a proposed rule is to be issued. However, the agency does expect and encourages other health organizations, public, private, and governmental, to submit comments on all proposed actions on health claims.

With respect to the suggested scoring system, FDA does not believe that such a system would be practicable because of the necessity for the agency to exercise its scientific judgment to give more weight to those studies of greater significance. Such significance may vary greatly from one situation to another, depending upon the nature of the evidence in each study. A scoring system might, under such circumstances, not fairly evaluate the merits of the studies.

One comment pertained to section 403(r)(4)(C) of the act which provides that if a petition for a health claim regulation relies on a report from an authoritative scientific body of the United States, the agency must consider such report and must justify any decision rejecting the conclusions of such report. The comment advised that similar consideration should apply with respect to other reputable scientific data that are submitted in support of the petition.

The agency does not agree. Section 403(r)(4)(C) of the act imposes upon FDA an obligation to justify rejection of conclusions of a report from an authoritative scientific body of the United States. Congress obviously believed that FDA should have strong grounds for not agreeing with such reports because of the high credibility of U.S. Government bodies. However, there is no indication in the legislative history of the 1990 amendments of an intent for FDA to have a similar burden

for reports not generated by such Government bodies. For such situations, the agency is only required to state the reasons for the denial of the recommendation. However, FDA intends to fully and fairly evaluate any scientific reports that are submitted to the agency in support of a health claim. The agency intends to consider such reports as part of the totality of evidence on the substance-disease relationship.

Several comments recommended that the agency establish a distinct and separate procedure (and consequently distinct and separate requirements for petitions) for determining the propriety and validity of health claims for dietary supplements. These comments stated that Congress intended that dietary supplements be considered under a more lenient standard than conventional foods and recommended that health claims for dietary supplements be based on significant scientific evidence and not significant scientific agreement. The comments stated that different standards should be applied to foods and dietary supplements because of FDA's disparate treatment of dietary supplements in the past. Some of these comments recommended that health claims be classified in three categories depending on the abundance of the scientific evidence and strength of scientific support.

FDA recognizes that dietary supplements are not subject to section 403(r)(3) and (r)(4) of the act. However, as explained fully above, FDA has carefully considered the discussion of dietary supplements in both the Senate and House, its obligations under the act, and the question of what standard and procedure are most appropriate to use in assessing and ensuring the validity of health claims for dietary supplements. Based on this consideration, FDA is proposing to apply the same scientific standard to health claims for dietary supplements of vitamins, minerals, herbs, and other similar nutritional substances as for conventional foods because the agency considers this standard to be the appropriate standard for ensuring the validity of all such claims. For the same reasons, as discussed above, FDA finds it appropriate under section 403(r)(5)(D) of the act and section 3(b)(1)(A)(x) of the 1990 amendments to make petitions to authorize claims on dietary supplements subject to the same requirements that apply to petitions for claims for conventional foods. FDA is proposing these requirements for dietary supplements because they will ensure that the agency has the information that it needs to assess the validity of claims for substances in these foods. Because FDA is proposing the same requirements for petitions on substances in dietary supplements as for substances in conventional foods, it is not distinguishing between dietary supplements and conventional foods in proposed § 101.70.

2. General Requirements and Provisions for Petitions

The agency is proposing to establish § 101.70 as the general procedural regulation for petitions for health claims. Section 101.70(a) through (d) address general issues and requirements such as the incorporation of various types of information into the petition and standard agency requirements pertaining to clinical and nonclinical studies submitted to the agency for review. Section 101.70(e) provides that all types of data and information in petitions for health claims are available for public disclosure after a petition is filed except for information that would identify a person or a third party, such as a physician or hospital, involved in a report. FDA is proposing no other exceptions to full disclosure because the statute does not provide for any exceptions, and because, as the agency explained above, it has tentatively concluded that the best way to assure the validity of a claim, either for a nutrient or for substance in a dietary supplement, is on the basis of publicly available scientific evidence. However, when FDA denies a petition before it is filed, the agency is proposing in § 101.70(j)(2) that no part of the petition will be made available to the public. This provision conforms to the requirements of section 403(r)(4)(A)(i) of the act and provides the same protection for petitions for substances in dietary supplements. FDA is also proposing to amend § 20.100, by adding § 20.100(c)(34), to reflect the provisions on the availability of records in proposed § 101.70.

Elsewhere in this issue of the **Federal Register**, FDA is publishing several documents that propose to find that certain substance and disease relationships are not valid. (In this document, FDA is proposing to establish § 101.17 in which the agency will list the topics for which it makes such a determination.) Those determinations are being processed through rulemaking proceedings because the 1990 amendments specifically directed the Secretary of Health and Human Services (and by delegation, FDA) to make the determinations (section 3(b)(1)(A)(vi) and (b)(1)(A)(x) of the 1990 amendments). With such specific direction, the agency believes that it is more appropriate to formalize its determinations through rulemaking rather than informally announcing its findings. However, while this course of action may be practicable for the 10 determinations mandated by the 1990 amendments, FDA does not believe it would be so for the many determinations that the agency may have to make in response to future petitions. Instead, FDA believes that its responses to petitions need to be made in the same manner as other petitions to change its food regulations. Specifically, the agency intends to advise firms of the specific reasons for denials without instituting a rulemaking proceeding.

FDA recognizes that in some circumstances there may be considerable interest in the agency's reasons for issuing denials, and that some firms may want to submit additional data that might result in a different FDA finding. Such firms may wish to consult the public listing of those health claims petitions that have been accepted for filing for issues of particular concern. Although denials of petitions not accepted for filing will not be released to the public, filed petitions will be fully available for public disclosure. Where the agency has denied a filed petition, interested parties may wish to review FDA reasons for denial before submitting an additional petition concerning a health claim.

Section 101.70(f) sets forth the proposed format for a health claim petition. It specifies the types of data and other requirements that the agency believes are necessary to provide for an efficient review and to demonstrate that the proposed substance-disease relationship complies with the requirements established under the 1990 amendments.

As proposed in format item A, the petition must include one or more model health claims that may be used on a food label or in labeling for a food to characterize the relationship of the substance in the food to a disease or health-related condition. This item is included among the petition requirements because FDA has tentatively concluded that it is valuable to include a model health claim in any authorizing regulation. Given the short timeframes under which FDA must review a petition, it would be difficult for the agency to prepare a model claim. Therefore, FDA is proposing to require that a model health claim be submitted as part of the petition.

In proposed format item B, the petitioner is to address how the substance conforms to the requirements in proposed § 101.14(b). These

requirements are discussed in section IV.B. of this document. One requirement is that the use of the substance, or the food ingredient of which the substance is a component, at the levels necessary to justify a claim be demonstrated by the proponent of the claim, to FDA's satisfaction, to be safe and lawful under the applicable food safety provisions of the act.

For petitions where the subject substance is a component of a food ingredient, the agency is proposing to require that the petitioner compile a comprehensive list of the specific ingredients that could be added to food to supply the substance in the food bearing the health claim. The agency is also proposing to require that, for each ingredient listed, the petitioner demonstrate that the use of the ingredient is safe and lawful under the applicable food safety provisions of the act. This showing can be made by a showing that the use of the ingredient is GRAS, listed as a food additive, or authorized by a prior sanction. Where the GRAS status is addressed in agency regulations (e.g., listed in Part 182 or affirmed in Part 184), the petition can cite the specific regulation. Where the GRAS status is not specifically addressed in agency regulations (e.g., where the GRAS status is based on common use in food prior to January 1, 1958 or based on conformance with the general principles stated in § 170.30(d)), or where there is a prior sanction, the petitioner must demonstrate, to the agency's satisfaction, that this requirement is met.

With respect to the requirement in proposed § 101.14(b)(1) that the U.S. population must be at risk for a disease or condition to permit a health claim, or that the petition submitted by the proponent of the claim otherwise explains the prevalence of the disease or health-related condition in the U.S. population and the relevance of the claim in the context of the total daily diet, proposed format item C requires that the necessary information be provided. It should be noted that the prevalence of the disease or health-related condition is of greater importance than the extent of the population's inadequate dietary intake of a substance. In particular, there may be data supporting that all or a significant part of the population has, or may have, an inadequate dietary intake of a substance. Such data are of value in justifying authorizing a health claim only in cases where the relationship of inadequate intake of a substance to the condition or disease has been satisfactorily established.

Information on the prevalence of a disease or condition is necessary because data from food intake surveys are commonly interpreted as showing that some segments of the population consume inadequate levels of nutrients. However, such surveys are generally poor predictors of nutritional status. There are several reasons for this apparent inconsistency. It is generally accepted, and controlled studies show (Ref. 19), that consumers who participate in a survey tend to underreport information on food consumption. Further, use of RDAs as criteria for assessing adequate or inadequate nutritional status fails to account for the large safety factor built into the RDAs for adequate nutrient intake by individuals in a population (Ref. 20). In addition, survey data show that a large segment of the population regularly consumes vitamin, mineral, and other dietary supplements that are not adequately recorded in surveys or studies of food consumption (Ref. 21).

For these reasons, the agency has had a longstanding policy that the only reliable means of determining the nutritional adequacy of diets of the population is through the use of clinical and biochemical measures to assess nutritional status. Data from the National Health and Nutrition Examination Survey have frequently been used and generally indicate that the level of nutrient deficiencies is very low or nonexistent for most nutrients. Iron is an exception based on observations of how iron stores in women of childbearing ages and among young children during rapid growth.

Proposed format item C also specifies the requirements to be addressed in the summary of scientific data in support of the claim. This summary must establish that the proposed claim meets the scientific standard provided for in proposed § 101.14(c).

If the claim is intended for a specific group within the population, the petitioner's analysis shall specifically address the dietary practices of such group and shall include data sufficient to demonstrate that the dietary analysis is representative of such group (e .g., adolescents or the elderly).

Proposed format item D requires the submission of analytical data showing the amount of a substance present in representative foods that would be candidates to bear the claim and specifies that the data be obtained using the Association of Official Analytical Chemists (AOAC) methods, where available, or other valid methodology along with submission of the methodology and its validation. Data on the amount of the substance in various foods will enable the agency to evaluate the usefulness of the claim in the context of the total diet.

Proposed format item E specifies the attachments to be submitted with the petition. These attachments include the scientific reports, studies, and other data and literature searches used to support the petition.

Proposed format item F requires that the petitioner include either a claim for a categorical exclusion under § 25.24 or an environmental assessment under § 25.31.

Proposed § 101.70(g) sets forth how the submitted data in the petition are to be organized and identified and permits the petitioner to incorporate by reference any data from an earlier petition.

Proposed § 101.70(h) requires that the petition include a statement signed by the person responsible for the petition that, to the best of his or her knowledge, it is a representative and balanced submission that includes unfavorable information, as well as favorable information, known to him/her to be pertinent to the evaluation of the proposed health claim.

Proposed § 101.70(i) requires that the petition be signed by the petitioner or by his/her attorney or agent, or (if a corporation) by an authorized official.

The proposed procedures for agency action on the petition in § 101.70(j) (1), (j) (2), and (j) (3) reflect the requirements of section 403(r) (4) (A) (i) of the act. For fairness, FDA is proposing to apply the same procedures in its review of petitions involving substances in dietary supplements. Further, the agency is proposing therein to notify the petitioner of receipt of the petition within 15 days of receipt.

Finally, with respect to petitions, the agency has proposed elsewhere in this issue of the **Federal Register** to amend 21 CFR 5.61 to redelegate from the Commissioner of Foods and Drugs to the Director and Deputy Director of the Center for Food Safety and Applied Nutrition, all the functions of the Secretary concerning petitions for label claims under section 403(r) of the act for both nutrient content and health claims that do not involve controversial issues. For petitions for health claims, such functions consist of the issuance of notices of proposed rulemaking and final rules concerning authorized health claims and the issuance of letters concerning the filing or denial of a petition. These proposed redelegations will facilitate timely agency action on these petitions given the short timeframes for agency action imposed

by the 1990 amendments. The proposed redelegations are similar to those proposed elsewhere in this issue of the Federal Register in the proposal concerning nutrient content claims which, like health claims, were designated by section 403(r) of the act to be used on food labels and in labeling only in conformity with regulations promulgated by the agency.

V. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the Federal Register. The agency requests comments on the RIA.

VI. Environmental Impact

The agency has determined under 21 CFR 25.24 that this proposed rule is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required. The proposed requirements pertaining to health claims on food labeling qualify for a categorical exclusion under 21 CFR 25.24(a) (11) and the proposed requirements pertaining to petitions requesting approval for the use of health claims for specific substances in food qualify for exclusion under 21 CFR 25.21(a) (8).

VII. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VIII. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 pm., Monday through Friday.

The agency has determined that 90 days is the maximum time that it can provide for the submission of comments and still meet the statutory timeframe for the issuance of final regulations on health claims. Thus, the agency is advising that it will not consider any requests under 21 CFR 10.40(b) for extension of the comment period beyond February 25, 1992. The agency must limit the comment period to no more than 90 days to assure sufficient time to develop a final rule based on this proposal and the comments it receives.

IX. Paperwork Reduction Act

In accordance with the Paperwork Reduction Act of 1980 (44 U.S.C. chapter 35), the provisions of § 100.70 *Petitions for health claims* relating to submission of petitions to FDA will be submitted for approval to the Office of Management and Budget (OMB). These provisions will not be effective until FDA obtains OMB approval. FDA will give notice of OMB approval of these requirements in the Federal Register as part of any final rule that is based on this proposal.

List of Subjects

21 CFR Part 20

Confidential business information, Courts, Freedom of information, Government employees.

21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR parts 20 and 101 be amended as follows:

Part 20—PUBLIC INFORMATION

1. The authority citation for 21 CFR part 20 continues to read as follows:

Authority: Section 201–903 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321–393); secs. 301, 302, 303, 307, 310, 311, 351, 352, 354–360F, 361, 362, 1701–1706, 2101 of the Public Health Service Act (42 U.S.C. 241, 242, 242a, 242l, 242n, 243, 262, 263, 263b–263n, 264, 265, 300u–300u–5, 300aa–1); 5 U.S.C. 552; 18 U.S.C. 1905.

2. Section 20.100 is amended by adding a new paragraph (c)(34) to read as follows:

§ 20.100 Applicability; cross reference to other regulations.

* * * * *

(c) * * *

(34) Health claims petitions, in § 101.70 of this chapter.

Part 101—FOOD LABELING

3. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

4. Section 101.9 is amended by adding paragraph (k) (1) to read as follows:

§ 101.9 Nutrition labeling of food.

* * * * *

(k) * * *

(1) That the food, because of the presence or absence of certain dietary properties, is adequate or effective in the prevention, cure, mitigation, or treatment of any disease or symptom. Information about the relationship of a dietary property to a disease or health-related condition may only be provided in conformance with the requirements of § 101.14 and subpart E of part 101.

* * * * *

5. New § 101.14 is added to read as follows:

§ 101.14 Health claims: general requirements.

(a) *Definitions.* For purposes of this section, the following definitions apply:

(1) *Health claim* means any claim made on the label or in labeling of a food, including a dietary supplement, that expressly or by implication, including "third party" endorsements, written statements (e.g., a brand name including a term such as "heart"), symbols (e.g., a heart symbol), or vignettes, that characterizes the relationship of any substance to a disease or health-related condition. Implied health claims include only those statements, symbols, vignettes, or other forms of communication that a manufacturer intends, or would be likely to be understood, to assert or direct beneficial relationship between the presence or level of any substance in the food and a health or disease-related condition.

(2) *Substance* means a component of a conventional food or of a dietary supplement of vitamins, minerals, herbs, or other nutritional substances.

(3) *Nutritive value* means a value in sustaining human existence by such processes as promoting growth, replacing loss of essential nutrients, or providing energy.

(4) *Dietary supplement* means a food, other than a conventional food, that supplies a component with nutritive value to supplement the diet by increasing the total dietary intake of that substance. A dietary supplement includes a food for special dietary use within the meaning of § 101.9(a) (2) that is in conventional food form.

(5) *Disqualifying nutrient levels* means the levels of total fat, saturated fat, cholesterol, or sodium in a food above which the food will be disqualified from making a health claim. These levels are 11.5 grams (g) of fat, 4.0 g of saturated fat, 45 milligrams (mg) of cholesterol, or 360 mg of sodium, per reference amount commonly consumed, per label serving size, and per 100 g. Any one of the levels, on a per reference amount commonly consumed, a per label serving size, or a per 100 g basis, will disqualify a food from making a health claim.

(b) For a substance to be eligible for a health claim:

(1) The substance must be associated with a disease or health-related condition for which the general U.S. population, or an identified U.S. population subgroup (e.g., the elderly) is at risk, or, alternatively, the petition submitted by the proponent of the claim otherwise explains the prevalence of the disease or health related-condition in the U.S. population and the relevance of the claim in the context of the total daily diet and satisfies the other requirements of this section.

(2) If the substance is to be consumed as a component of a conventional food at decreased dietary levels, the substance must be a nutrient listed in 21 U.S.C. 343(q) (1) (C) or (D), or one that FDA has required to be included in the label or labeling under 21 U.S.C. 343 (q) (2) (A); and

(3) If the substance is to be consumed at other than decreased dietary levels:

(i) The substance must be consumed as a component of a conventional food or of a dietary supplement and contribute taste, aroma, or nutritive value, or any other technical effect listed in § 170.3(o) to the food and must retain that attribute when consumed at levels that are necessary to justify a claim; and

(ii) The substance must be a food ingredient or a component of a food ingredient whose use at the levels necessary to justify a claim has been demonstrated by the proponent of the claim, to FDA's satisfaction, to be safe and lawful under the applicable food safety provisions of the act.

(c) *Validity requirements.* FDA will promulgate regulations authorizing a health claim only when it determines, based on the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

(1) It must be supported by the totality of publicly available scientific evidence (including evidence from welldesigned studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) ; and

(2) There must be significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims that this support exists.

(d) *General health claim labeling requirements.* (1) When FDA determines that a health claim meets the validity requirements of paragraph (c) of this section, FDA will propose a regulation in subpart E of this part to authorize the use of that claim. If the claim pertains to a substance not provided for in §§ 101.9 or 101.36, FDA will propose amending these regulations to include declaration of the substance.

(2) When a regulation has been established in subpart E of this part providing for a health claim, firms may make claims based on the regulation in subpart E of this part, provided that:

(i) All label or labeling statements about the substance-disease relationship that is the subject of the claim are based on, and consistent with, the conclusions set forth in the summary of scientific information and model health claims provided in regulations in subpart E of this part;

(ii) The claim is limited to describing the value that ingestion (or reduced ingestion) of the substance, as part of a total dietary pattern, may have on a

particular disease or health-related condition;

(iii) The claim is complete, truthful, and not misleading. Where factors other than dietary intake of the substance affect the health benefit, such factors may be required to be addressed in the claim by a specific regulation in subpart E of this part;

(iv) All information required to be included in the claim appears in one place, in the same type size, without other intervening material: Except that the label may bear the statement, "See ____ for information about the relationship between ____ and ____," with the blanks filled in with references to the location of the labeling containing the health claim, the name of the substance, and the disease or healthrelated condition (e.g., "See attached pamphlet for information about calcium and osteoporosis"), with the entire claim appearing on the other labeling;

(v) The claim enables the public to comprehend the information provided and to understand the relative significance of such information in the context of a total daily diet; and

(vi) If the claim is about the effects of consuming the substance at decreased dietary levels, the level of the substance in the food is sufficiently low to justify the claim. To meet this requirement, if a definition for use of the term "low" has been established for that substance under this part, the substance must be present at a level that meets the requirements for use of that term, unless a specific alternative level has been established for the substance in Subpart E of this part. If no definition for "low" has been established, the level of the substance must meet the level established in the regulation authorizing the claim; or

(vii) If the claim is about the effects of consuming the substance at other than decreased dietary levels, the level of the substance in the food is sufficiently high and in an appropriate form to justify the claim. To meet this requirement, if a definition for use of the term "high" for that substance has been established under this part, the substance must be present at a level that meets the requirements for use of that term, unless a specific alternative level has been established for the substance in subpart E of this part. If no definition for "high" has been established, the level of the substance must meet the level established in the regulation authorizing the claim.

(3) Nutrition labeling shall be provided in the label or labeling of any food for which a health claim is made in accordance with §§ 101.9 and 101.36.

(e) *Prohibited health claims.* No expressed or implied health claim may be made on the label or in labeling for a food unless:

(1) The claim is specifically provided for in subpart E of this part; and

(2) The claim conforms to all general provisions of this section as well as to all specific provisions in the appropriate section of Subpart E of this part;

(3) None of the disqualifying levels identified in paragraph (a)(5) of this section is exceeded in the food, unless specific alternative levels have been established for the substance in subpart E of this part; or unless FDA has permitted a claim despite the fact that a disqualifying level of a nutrient is present in the food based on a finding that such a claim will assist consumers in maintaining healthy dietary practices, and, in accordance with the regulation in subpart E that makes such a finding, the label bears a referral statement that complies with § 101.13(h) highlighting the nutrient that exceeds the disqualifying level;

(4) No substance, other than one for which a "disqualifying nutrient level" is established, is present at an inappropriate level as determined in specific provisions of subpart E of this part; and

(5) The label does not represent or purport that the food is for infants and toddlers less than 2 years of age.

(f) The requirements of this section do not apply to:

(1) Infant formulas subject to section 412(h) of the Federal Food, Drug, and Cosmetic Act, and

(2) Medical foods defined by section 5(b) of the Orphan Drug Act.

(g) *Applicability.* The requirements of this section apply to foods intended for human consumption that are offered for sale.

6. Subpart E, consisting of §§ 101.70 and 101.71, is added to read as follows:

Subpart E—Specific Requirements for Health Claims

Sec.

101.70 Petitions for health claims.
101.71 Health claims: Claims not authorized.

Subpart E—Specific Requirements for Health Claims

§ 101.70 Petitions for health claims.

(a) Any interested person may petition the Food and Drug Administration (FDA) to issue a regulation regarding a health claim. The petition shall be submitted in quadruplicate. If any part of the material submitted is in a foreign language, it shall be accompanied by an accurate and complete English translation. The petition shall state the petitioner's post office address to which any correspondence required by section 403 of the Federal Food, Drug, and Cosmetic Act may be sent.

(b) Pertinent information may be incorporated in, and will be considered as part of, a petition on the basis of specific reference to such information submitted to and retained in the files of FDA. Any reference to published information shall be accompanied by reprints, or easily readable copies of such information.

(c) If nonclinical laboratory studies are included in a petition, the petition shall include, with respect to each nonclinical study contained in the petition, either a statement that the study has been conducted in compliance with the good laboratory practice regulations as set forth in part 58 of this chapter, or, if any such study was not conducted in compliance with such regulations, a brief statement of the reason for the noncompliance.

(d) If clinical or other human investigations are included in a petition, the petition shall include a statement that they were either conducted in compliance with the requirements for institutional review set forth in part 56 of this chapter, or were not subject to such requirements in accordance with § 56.104 or § 56.105, and a statement that they were conducted in compliance with the requirements for informed consent set forth in part 50 of this chapter.

(e) All data and information in a health claim petition are available for public disclosure after the notice of filing of petition is issued to the petitioner, except that clinical investigation reports, adverse reaction reports, product experience reports, consumer complaints, and other similar data and information shall only be available after deletion of:

(1) Names and any information that would identify the person using the product.

(2) Names and any information that would identify any third party involved with the report, such as a physician or hospital or other institution.

(f) Petitions for a health claim shall include the following data and be submitted in the following form:

(Date)
Name of petitioner _____
Post office address _____
Subject of the petition _____

Food and Drug Administration, Regulatory Affairs Staff (HFF-204), Office of Nutrition and Food Sciences, 200 C St. SW., Washington, DC 20204.

The undersigned, _____, submits this petition pursuant to section 403(r) (4) or 403(r) (s) (D) of the Federal Food, Drug, and Cosmetic Act with respect to (statement of the substance and its health claim).

Attached hereto, in quadruplicate, and constituting a part of this petition, are the following:

A. Model health claim. One or more model health claims that represent label statements that may be used on a food label or in labeling for a food to characterize the relationship between the substance in a food to a disease or health-related condition that is justified by the summary of scientific data provided in section C of the petition. The model health claim shall include:

1. A brief capsulized statement of the relevant conclusions of the summary, and

2. A statement of how this substance helps the consumer to attain a total dietary pattern or goal associated with the health benefit that is provided.

B. Preliminary requirements. A complete explanation of how the substance conforms to the requirements of § 101.14 (b). For petitions where the subject substance is a food ingredient or a component of a food ingredient, the petitioner should compile a comprehensive list of the specific ingredients that will be added to the food to supply the substance in the food bearing the health claim. For each such ingredient listed, the petitioner should state how the ingredient complies with the requirements of § 101.14(b) (3) (ii), e.g., that its use is GRAS, listed as a food additive, or authorized by a prior sanction issued by the agency, and what the basis is for the GRAS claim, the food additive status, or prior sanctioned status.

C. Summary of scientific data. The summary of scientific data provides the basis upon which authorizing a health claim can be justified as providing the health benefit. The summary must establish that, based on the totality of publicly available scientific evidence (including evidence from well designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), there is significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The summary shall state what public health benefit will derive from use of the claim as proposed. If the claim is intended for a specific group within the population, the summary shall specifically address nutritional needs of such group and shall include scientific data showing how the claim is likely to assist in meeting such needs.

The summary shall concentrate on the findings of appropriate review articles, National Institutes of Health consensus development conferences, and other appropriate resource materials. Issues addressed in the summary shall include answers to such questions as:

1. Is there an optimum level of the particular substance to be consumed beyond which no benefit would be expected?

2. Is there any level at which an adverse effect from the substance or from foods containing the substance occurs for any segment of the population?

3. Are there certain populations that must receive special consideration?

4. What other nutritional or health factors (both positive and negative) are important to consider when consuming the substance?

In addition, the summary of scientific data shall include a detailed analysis of the potential effect of the use of the proposed claim on food consumption, specifically any change due to significant alterations in eating habits and corresponding changes in nutrient intake resulting from such changes in food consumption. The latter item shall specifically address the effect on the intake of nutrients that have beneficial and negative consequences in the total diet.

If the claim is intended for a significant subpopulation within the general U.S. population, the analysis shall specifically address the dietary practices of such group, and shall include data sufficient to demonstrate that the dietary analysis is representative of such group (e.g., adolescents or the elderly).

If appropriate, the petition shall explain the prevalence of the disease or health-related condition in the U.S. population and the relevance of the claim in the context of the total daily diet.

Also, the summary shall demonstrate that the substance that is the subject of the proposed claim conforms to the definition of the term "substance" in paragraph (a) (2) of § 101.14.

D. Analytical data that show the amount of the substance that is present in representative foods that would be candidates to bear the claim should be obtained from representative samples using methods from the Association of Official Analytical Chemists (AOAC), where available. If no AOAC method is available, the petitioner shall submit the assay method used and data establishing the validity of the method for assaying the substance in food. The validation data should include a statistical analysis of the analytical and product variability.

E. The petition shall include the following attachments:

1. Copies of any computer literature searches done by the petitioner (e.g., Medline).

2. Copies of articles cited in the literature searches and other information as follows:

a. All information relied upon for the support of the health claim, including copies of publications or other information cited in review articles and used to perform meta-analyses.

b. All information concerning adverse consequences to any segment of the population (e.g., sensitivity to the substance).

c. All information pertaining to the U.S. population.

F. The petitioner is required to submit either a claim for categorical exclusion under § 25.24 of this chapter or an environmental assessment under § 25.31 of this chapter.

Yours very truly,
Petitioner

By _____
(Indicate authority)

(g) The data specified under the several lettered headings should be submitted on separate pages or sets of pages, suitably identified. If such data have already been submitted with an earlier application from the petitioner or any other final petition, the present petition may incorporate it by specific reference to the earlier petition.

(h) The petition shall include a statement signed by the person responsible for the petition that, to the best of his/her knowledge, it is a representative and balanced submission that includes unfavorable information as well as favorable information, known to him/her to be pertinent to the evaluation of the proposed health claim.

(i) The petition shall be signed by the petitioner or by his/her attorney or agent, or (if a corporation) by an authorized official.

(j) *Agency action on the petition.* (1) Within 15 days of receipt of the petition, the petitioner will be notified by letter of the date on which the petition was received. Such notice will inform the petitioner that the petition is undergoing agency review and that the petitioner will subsequently be notified of the agency's decision to file for comprehensive review or deny the petition.

(2) Within 100 days of the date of receipt of the petition, FDA will notify the petitioner by letter that the petition has either been filed for comprehensive review or denied. The agency will deny a petition without reviewing the information contained in C. *Summary of Scientific Data* if the information in B. *Preliminary Requirements* is inadequate in explaining how the substance conforms to the requirements of § 101.14(b). If the petition is denied, the notification will state the reasons therefor, including justification of the rejection of any report from an authoritative scientific body of the U.S. Government. If filed, the date of the notification letter becomes the date of filing for the purposes of this regulation. A petition that has been denied will not be made available to the public. A filed petition will be available to the public to the extent provided under paragraph (e) of this section.

(3) Within 90 days of the date of filing, FDA will by letter of notification to the petitioner:

(i) Deny the petition, or

(ii) Inform the petitioner that a proposed regulation to provide for the request use of the health claim will be published in the Federal Register. If the petition is denied, the notification will state the reasons therefor, including justification for the rejection of any report from an authoritative Scientific body of the U.S. Government. FDA will

publish the proposal to amend the regulations to provide for the requested use of the health claim in the **Federal Register** within 90 days of the date of filing. The proposal will also announce the availability of the petition for public review.

§ 101.71 Health claims: claims not authorized.

In response to the Nutrition Labeling and Education Act of 1990, FDA has reviewed the evidence on the following topics that Congress specifically asked FDA to evaluate and has concluded that there is no basis for claims about the following:

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

[FR Doc. 91-27151 Filed 11-26-91; 8:45 am]

BILLING CODE 4160-01-M

---

21 CFR Part 101

[Docket No. 91N-0098]

RIN 0905-AD08

Food Labeling: Health Claims; Dietary Fiber and Cancer

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing that after reviewing the available evidence, it tentatively finds that a basis does not exist on which to authorize the use on foods, including dietary supplements, of health claims relating to an association between ingestion of dietary fiber and reduction in risk of cancer. While data support an association between consumption of fiber-rich plant foods and reduced risk of cancer, FDA tentatively finds that it cannot attribute this effect to the fiber itself. Therefore, FDA specifically requests comments on this topic. FDA has reviewed the relationship between this dietary component and this disease under the provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments).

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the 1990 amendments.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Joyce J. Saltsman, Center for Food Safety and Applied Nutrition (HFF-265), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-485-0316.

SUPPLEMENTARY INFORMATION:

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101-535), which amend the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (and FDA by delegation) to issue regulations authorizing claims on the label or labeling of foods characterizing the relationship between a food component and a disease or health-related condition. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this issue of the **Federal Register** is a proposed rule "Food Labeling: General Requirements for Health Claims for Food" to establish general requirements for health claims on food labels and labeling that characterize the relationship of nutrients, including vitamins or minerals, herbs, or other nutritional substances (referred to generally as "substances") in food to a disease or health-related condition. In this companion document, FDA has tentatively concluded that such claims would only be justified for substances in conventional foods as well as in dietary supplements if the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) supports a claim, and if there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, about such support.

The 1990 amendments also require (section 3(b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)) that within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act, and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including dietary fiber and cancer, meet the requirements of the act. In this document, the agency will consider whether a claim on the label or labeling of food or food products on the relationship between dietary fiber and cancer would be justified under the standard proposed in the companion document.

B. Basis for Considering a Claim Relating Dietary Fiber and Cancer

1. Cancer

Cancer accounts for about one of every five deaths and is the second leading cause of death in the United States (DHHS/PHS, 1990). Deaths from cancer numbered more than 475,000 in 1987. The overall economic cost of cancer, including direct health care costs and losses due to morbidity and mortality, was estimated to be $72.5 billion. In addition, the social impact of cancer can be measured in part by potential years of life lost by death before age 65. Potential years of life lost were 18 million for cancer compared to 15 million for heart disease (Ref. 46).

The risk of occurrence of cancer differs markedly for various sites. In 1990, lung cancer accounted for 35 percent of all cancer deaths in men. Colorectal cancer and prostate cancer each accounted for 11 percent of cancer deaths in men. The leading causes of cancer deaths among women were lung cancer (21 percent of cancer deaths), breast cancer (18 percent), and colorectal cancer (13 percent) (Ref. 46).

2. Dietary Fiber

Dietary fiber is comprised of components of plant materials that are resistent to human digestive enzymes (Refs. 12 and 24). These components are predominantly nonstarch polysaccharides and lignin and may include, in addition, associated substances (Ref. 12). To date, the best documented and most widely accepted nutritional role for dietary fibers is for normal bowel function and health (Ref. 24). It is estimated that current dietary fiber intakes of 10 to 15 grams (g) per day (6 to 7 g per 1000 kilocalories) in the United States are less than optimal for meeting needs for normal bowel function and health (Refs. 22 and 24). Significant increases in this level of intake have been recommended frequently (Ref. 24).

Based on currently available analytical methods, dietary fiber is measured both as total dietary fiber and as the subcomponents of soluble and

insoluble fibers (Ref. 24). Until recently, epidemiologic and other human studies were not able to evaluate total dietary fiber intake because the majority of food composition tables contained no values for total dietary fiber content of foods. In addition, no standardized definitions of dietary fiber or dietary fiber components have been agreed upon.

Naturally occurring fibers in food are usually a mixture of insoluble fibers such as cellulose and lignin, soluble fibers such as pectins, gums, and mucilages, and combinations of soluble and insoluble fibers such as hemicelluloses (Ref. 25). The proportions and types of fiber subcomponents vary among foods (e.g., oatmeal contains relatively large amounts of soluble fiber, while whole wheat bread contains relatively large amounts of insoluble fiber). Fiber content also varies within a food item or food group depending on maturity of the plant, storage and ripening conditions, and food processing techniques used, if any.

In evaluating the biological effects and health consequences of total dietary fiber, dietary fiber intake has been expressed as:

(a) As total dietary fiber or as the major fiber subcomponents (soluble and insoluble fibers);

(b) Fiber-containing foods (e.g., whole grains, legumes, fruits, vegetables);

(c) Fiber-rich food isolates (e.g., wheat bran, oat bran, corn bran, soy isolates); or

(d) Isolated and purified fibers (e.g., cellulose, pectins, lignin).

3. Basis for Evaluating a Relationship Between Dietary Fiber and Risk of Cancer

Interest in a possible role of dietary fiber in reducing the risk of cancer was stimulated by Burkitt and Trowell's suggestion that the rarity of cancer of the large intestine in Africa may be the result of a protective effect of dietary fiber (Ref. 5). These authors also suggested that fiber may be protective against other diseases that are common in the west, such as coronary heart disease and colorectal cancer. Subsequently, considerable research has been conducted on the role of dietary fiber and its relationship to risk of cancer at various sites.

Populations consuming diets rich in fiber-containing foods (vegetables, fruits, and grains) have significantly lower rates of cancer of the colon, breast, lung, oral cavity, larynx, esophagus, stomach, bladder, uterine cervix, and pancreas than populations consuming diets low in fiber-containing foods (Refs. 46 and 47). Available evidence also shows that populations consuming diets high in fiber also tend to consume diets that are low in fat and total energy (calories), high in vitamins and minerals (including vitamin A precursors and vitamin C), high in plant foods, and low in animal foods. Thus, it has not usually been possible to separate the effects of dietary fiber from those of other dietary components or a combination of dietary components.

Estimations of the impact of dietary fiber and other dietary components on total cancer incidence have been based on evidence regarding established relationships between dietary factors and cancer risk, the dramatic shifts in site-specific cancer rates among migrants to the United States, secular trends in cancer for which a dietary etiology is likely, and supportive evidence from animal experiments (Ref. 30).

The strongest support for a possible protective effect of fiber-rich diets is for cancers of the colon and rectum (colorectal cancers), the second leading cause of all cancer deaths in the United States (Ref. 46). Most of the epidemiologic associations between dietary fiber and risk of cancer relate to cancer of the colon. Virtually all laboratory animal studies on the topic of dietary fiber and cancer have focused on colon carcinogenesis.

The specific health claim topic described in the 1990 amendments was "dietary fiber and cancer." FDA, however, limited its review of the scientific evidence to cancers of the colon and rectum. This limitation was deemed appropriate because, as noted above, the great majority of epidemiologic and intervention studies have focused on colon cancer, as have virtually all animal studies in this area.

FDA recognizes that some fibers have been reported to modify the biological actions of hormones and thus reduce the risk of hormone-related cancers such as breast cancer (Ref. 22). Lanza et al. (Ref. 22) reviewed studies relating diets rich in fruits, vegetables, or grains and decreased risk of breast cancer, and also discussed mechanisms by which dietary fiber may modify risk of cancer at this site. FDA also recognizes that dietary fiber has also been studied with respect to its possible involvement in risk of stomach, ovarian, and endometrial cancers. Because the number of studies of the association between dietary fiber and cancers at these other sites is limited, review of such studies is not included in this document. The relationship of dietary fiber to cardiovascular disease is addressed in a companion document published elsewhere in this issue of the Federal Register. The relationships of antioxidant vitamins and cancer and fat and cancer are addressed in two other companion documents also published elsewhere in this Federal Register.

C. Regulatory and Legislative History

1. Early Claims for Dietary Fiber

Claims for health benefits to be derived from consuming fiber-containing foods have been made for over 100 years. Early interest focused on the benefits of wheat bran as a promoter of regular bowel function. Claims for wheat bran on breakfast cereal packages were popular in the early 1900's, and the importance of adding "bulk" to the diet by the addition of dietary fiber was emphasized in advertisements promoting the benefits of certain fibers as aids to digestion and in relieving constipation. Such claims on packages were largely unregulated until after the passage of the act in 1938. Under the act, such claims evidence an intent that the products are to be used as drugs, and therefore, subjected the products to the requirements of drug law. As a result, the use of health-related claims on cereal products virtually stopped until recently.

On November 22, 1941, the agency published regulations that included labeling requirements for "nondigestible carbohydrates" (6 FR 5921). At that time, foods having a high fiber content were valued because decreases in caloric density were achieved when such products were added to foods such as bread. Based on the analytical procedures available at that time, the fibrous plant components of food had to be labeled as "crude fiber," which is compositionally and quantitatively different from dietary fiber.

During the late 1970 s, FDA sought to revise its regulations to include as fiber other fractions of carbohydrates, in addition to crude fiber, that are not digested by human enzymes. In doing so, the agency noted that the scientific evidence linking fiber to health outcomes was limited. In the Federal Register of December 21, 1979 (44 FR 75990), the agency stated that "some advocates of higher fiber diets have theorized that the incidence of bowel cancer and other intestinal diseases may be related to the decreased amount of fiber in western diets * * * and that the relationship of dietary fiber to health remains controversial" Currently § 105.66 (21 CFR 105.66) provides for the declaration of nonnutritive substances, but there is no regulation for declaration of fiber.

2. Food Additive Status

Substances that are added to food may be categorized based on their use as generally recognized as safe (GRAS) ingredients, food additives, or substances subject to a sanction or approval granted by the FDA or the United States Department of Agriculture prior to September 6, 1958. The use of substances may be GRAS under the general principles set forth in § 170.30 (21 CFR 170.30), listed as GRAS in part 182 (21 CFR part 182), or affirmed as GRAS in part 184 (21 CFR part 184). FDA's listings of food additives and affirmations that the use of a substance for direct addition to food is GRAS generally include the particular food categories in which (as defined in § 170.3(n)), and specific technical effects for which (as defined in § 170.3(o)), the substance may be used.

"Fiber" is not considered to be either a food category or a technical effect according to the above definitions, and ingredients that are added to food are therefore not regulated as "fiber." However, FDA has regulated a number of isolated or purified fibers for specific technical effects in various food categories. For example, xanthin gum is listed as a food additive for use as a stabilizer, emulsifier, thickener, suspending agent, bodying agent, or foam enhancer (§ 172.695 (21 CFR 172.695)); methylcellulose is listed as a multiple purpose GRAS substance (21 CFR 182.1480); and pectins are affirmed as GRAS for use as an emulsifier, stabilizer, or thickener (§ 184.1588). Guar gum is affirmed as GRAS for specific conditions of use that include those as an emulsifier, formulation aid, firming agent, and thickener (§ 184.1339). Guar gum has not been listed for use as a source of fiber, and under some circumstances, it has been shown to cause esophageal blockage and thus, to be a health hazard. These and many other isolated or purified gums and fibers have no established history of food use or safety as fiber supplements.

3. Dietary Fiber and Cancer as Subjects of Health Claims

Prompted by the use, beginning in 1984, of information on high-wheat bran cereal packages stating that high fiber diets may reduce the risk of cancer, and by issuance of interim dietary fiber recommendations by the National Cancer Institute, FDA proposed in 1987 to amend the food labeling regulations to allow the use of health messages (hereafter, the term "health claim" is used for consistency with section 403(r) of the act) on labels and food labeling (52 FR 28843, August 4, 1987). The agency stated that food labeling could have an important influence on the public s food choices, and that truthful, nonmisleading health claims could increase the consumer's understanding of health benefits that can result from adhering to a sound and nutritious diet. This proposal set forth criteria for the evaluation of health claims.

In the **Federal Register** of February 13, 1990 (55 FR 5176), FDA published a reproposed rule on health claims that withdrew the 1987 proposal and proposed to establish procedures for permitting valid and reliable consumer information on food labels. The agency noted that the 1987 proposal was too ambiguous to be workable in preventing misleading claims. FDA thus proposed to issue tighter requirements for health claims. The agency also proposed to evaluate the scientific evidence on six possible topics for claims, including dietary fiber and cancer.

On November 8, 1990, the President signed the 1990 amendments, that authorize FDA to issue regulations concerning claims on the label or labeling of foods that characterize the relationship between a substance and a disease or a health-related condition. As stated above, this law identified 10 substance-disease topics, including dietary fiber and cancer, that FDA is to consider to determine whether they are appropriate subjects of health claims.

D. Evidence Considered in Reaching the Decision

As noted above, the strongest support for a possible protective effect of fiber-rich diets is for colorectal cancers, major causes of cancer deaths in men and women in the United States. For this reason, FDA limited its review of the scientific evidence to the topic of dietary fiber and cancers of the colon and rectum (colorectal cancers). Most of the epidemiologic associations between dietary fiber and risk of cancer relates to cancer of the colon and virtually all laboratory animal studies in this topic area have focused on colon carcinogenesis.

The agency has reviewed the relevant scientific evidence on dietary fiber and colorectal cancers. The scientific evidence included descriptions of evidence reviewed and conclusions reached in Federal Government documents including "The Surgeon General's Report Nutrition and Health" (Ref. 47), the Department of Agriculture and the Department of Health and Human Services "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 45), and the Department of Health and Human Services' "Healthy People 2000, National Health Promotion and Disease Prevention Objectives" (Ref. 46). The agency also reviewed the evidence and conclusions in other reviews by recognized scientific bodies including the Life Sciences Research Office (LSRO) report on "Physiological Effects and Health Consequences of Dietary Fiber" (Ref. 24), the National Academy of Sciences (NAS) "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 30), the National Research Council's (NRC) "Recommended Dietary Allowances" (Ref. 31), and the World Health Organization's "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 51).

The agency updated these reports by independently reviewing all human studies and all review articles published since the Federal Government documents and other documents mentioned above had completed their reviews of the literature on the relationship of dietary fiber and colorectal cancer. FDA considered animal studies to the extent that they clarified human studies or suggested possible mechanisms of action.

FDA also contracted with LSRO to independently evaluate current evidence since the fiber report LSRO issued in 1987 (Ref. 25). Finally, to ensure that its review of relevant evidence was complete, FDA requested in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas including dietary fiber and cancer identified in section 3(b)(1)(A) of the 1990 amendments. The agency reviewed and considered comments submitted in response to the **Federal Register** notice in developing this document.

E. Summary of Comments Received in Response to FDA Request for Scientific Data and Information

Responses to the March 28, 1991 **Federal Register** notice were received from 3 professional organizations, 10 industry and trade associations, the Canadian Government, 1 consumer association, and an individual consumer.

One of the professional organizations urged caution in determining the use of health claims on foods, and another called attention to the need for FDA to use independent judgment with regard to the use of health claims on dietary supplements. A third professional organization pointed out that the protective effect of fiber against cancer cannot be ascribed to dietary fiber alone. The comment stated that the interaction of fiber with other nutrients

in the diet must also be considered. The comment also expressed concern that food label claims would be misunderstood by the public.

Among 10 comments received from dietary supplement or food manufacturers and related trade associations, 7 submitted comments and evidence, including some unpublished studies, that supported their position that health claims on fiber and cancer should be allowed on foods. One acknowledged that although the evidence is usually considered inconclusive, there is enough evidence to support the view that increased consumption of food sources of fiber is associated with reduced rates of cancer (colorectal and breast). All scientific data submitted are discussed in the scientific summary portion of this document.

The Director General, Food Directorate, Health and Welfare, Canada submitted information on the regulatory status of health claims in that country. The Canadian Government is not in favor of health claims on fiber-containing foods because it is difficult to disassociate the effect of fiber from the metabolic effects of fat and energy intake that also are claimed to influence the development of colorectal cancer. Although it has been estimated that cancer incidence can be reduced by 35 percent by dietary changes, "it has been remarkably difficult to identify specific components of the diet that increase risk or provide protection in individuals" (Ref. 28). The comment said that this finding does not diminish the importance of diet as a factor in the maintenance of health but reinforces the importance of the whole diet rather than the contribution of individual components.

II. Review of the Scientific Evidence

A. Federal Government Documents

"The Surgeon General's Report Nutrition and Health" (Ref. 47) reviewed human and animal studies of fiber and colorectal cancer and noted that among epidemiologic studies, international correlation studies are the most consistent source of support for the relationship. The report found that case-control studies provided less consistent support, but that many of the epidemiologic studies were limited by the lack of information about the type of fiber consumed. The report also noted that rodent studies suggest the importance of type of dietary fiber, but the relevance of these animal models to human cancer needs to be determined. The report concluded that "while inconclusive, some evidence also suggests that an overall increase in intake of foods high in fiber might decrease the risk for colon cancer." The role of various types of fiber that differ in their effects on water-holding capacity, viscosity, bacterial fermentation, and intestinal transit time has not been resolved (Ref. 47). The report concluded that current evidence suggests the prudence of increasing consumption of whole grain foods and cereal products, vegetables (including dried beans and peas), and fruits (Ref. 47).

USDA/DHHS' "Nutrition and Your Health, Dietary Guidelines for Americans" (Ref. 45) noted that populations such as those in the United States with diets low in dietary fiber and complex carbohydrates and high in fat, especially saturated fat, tend to have more heart disease, obesity, and some cancers. The guidelines stated that just how dietary fiber is involved is not yet clear, and that the benefit from a higher fiber diet may be from the food providing the fiber rather than from the fiber alone (Ref. 45). The dietary guidelines recommended that the American population choose diets with plenty of vegetables, fruits, and grain products rather than use of fiber supplements. Excessive use of fiber supplements is associated with greater risk of intestinal problems and lower absorption of some minerals.

In "Healthy People 2000," the Public Health Service and the Department of Health and Human Services identified increased consumption of complex carbohydrates and fiber-containing foods by adults as a specific risk reduction objective (Ref. 46). Recommendations included increasing consumption of vegetables (including legumes) and fruits to 5 or more servings daily, and increasing consumption of grain products to 6 or more daily servings. The report noted that dietary patterns with higher intakes of vegetables (including legumes), fruits, and grain products are associated with a variety of health benefits, including decreased risk for some types of cancer (Ref. 46).

There are several unresolved issues related to dietary fiber and cancer prevention (Ref. 46). For example, the role of specific types of fiber has not been delineated. Other natural substances present in plant foods, such as carotenoids, indoles, and flavonoids might also be contributing to the observed protective association for certain cancers (Ref. 46).

B. Other Reviews by Recognized Scientific Bodies

Several other reviews by recognized scientific bodies of the role of diet, nutrition and health have been published recently (Refs. 24, 25, 30, 31, 51, and 52). The conclusions regarding dietary fiber and cancer reached in these reports are similar to those reached in the Federal Government reports above.

An expert advisory committee was convened in 1985 by the Health Protection Branch of the Department of National Health and Welfare of the Canadian Government to advise them on scientific and regulatory issues related to dietary fiber (Ref. 52). While this report did not specifically review the area of fiber and cancer, it did review broad issues related to dietary fiber in foods. The committee noted that the relationship between the physico-chemical properties of dietary fibers and their physiological effects is difficult to evaluate due to the complexity of the interactions of mixed fibers in foods and to, in some cases, the lack of uniformity in testing procedures. The committee also recommended that manufacturers of food products, to which non-native and/or novel fibers have been added to increase dietary fiber content, may be required to provide evidence substantiating the safety and efficacy of these products in terms of accepted physiological effects. Non-native fibers were defined as fibers from traditional foods but not naturally occurring in the foods to which they have been added; novel fibers were defined as those which have not traditionally been part of the human diet. The committee also recommended that manufacturers of products which have been substantially enriched with native fibers should also be prepared to provide proof of efficacy and safety on request.

LSRO concluded in its 1987 report that dietary fiber is an integral part of a healthy diet (Ref. 24). However, it also concluded that the available evidence is not sufficient to support specific, quantitative recommendations on the role of dietary fiber for reducing the risk of specific diseases in the general, healthy population. The report noted that correlational studies using data from different countries have suggested a protective effect of dietary fiber against colon cancer, but that such studies cannot adequately determine whether high fiber intake per se or the low fat intake associated with consumption of fiber-rich foods is responsible for the observed associations (Ref. 24). The report noted

that most international correlational studies are based on the same Food and Agricultural Organization (FAO) data base and thus lacked independence. The LSRO report concluded that studies correlating fiber intake and cancer incidence within a single population generally observed weaker associations than the international studies. In reviewing the case-control studies of fiber intake and colon cancer, the report noted inconsistencies in the results. Nine studies showed fiber-containing foods to provide a protective effect, eight studies showed no effect, and three studies suggested that fiber may be a risk factor for colon carcinogenesis. LSRO concluded (Ref. 24) following a review of animal studies, that only particular types of fiber (especially fiber from wheat bran) are protective against chemically-induced colon cancer in animal models.

The LSRO report (Ref. 24) recommended consumption by the healthy adult population of a wide variety of foods, such as whole-grain products, fruits, and vegetables, leading to a dietary fiber intake range of 20 to 35 g per day (approximately 10 to 13 g per 1000 calories).

The 1989 NAS report "Diet and Health" (Ref. 30) also recommended increased consumption of vegetables, fruits, breads, cereals, and legumes. The report concluded that the evidence for a protective role of fiber in colon cancer was inconclusive. The report noted inconsistency in the results of epidemiological studies, and that animal studies suggested that the type of dietary fiber is important in modulating the effects of a colon carcinogen. The NAS report also noted that the effects attributed to fiber in some studies may actually be produced by some other components of the diet. Thus, even where the evidence is strongest, it has not been possible to adequately separate the effects of fiber from those of other components of the diet (e.g. total calories, fats, vitamins, minerals, and nonnutritive constituents of fruits and vegetables) and nondietary factors (e.g. socioeconomic status) (Ref. 30). The overall assessment of the evidence by the NAS report was as follows: "In general, the evidence for a protective role of dietary fiber per se in coronary heart disease, colon and rectal cancers, stomach cancers * * * is inconclusive." (Ref. 30).

The NRC's "Recommended Dietary Allowances" (Ref. 31) stated that the consumption of diets rich in plant foods, and therefore fiber, is inversely related to the incidence of cardiovascular disease, colon cancer, and diabetes and noted that because an increase in dietary fiber consumption is almost invariably associated with a change in other dietary constituents, it is difficult to establish a clear relationship with dietary fiber alone (Ref. 31). The NRC recommends that a desirable fiber intake be achieved not by adding fiber concentrates to the diet, but by consumption of fruits, vegetables, legumes, and wholegrain cereals, which also provide minerals and vitamins (Ref. 31).

The reports summarized above were in agreement in their recommendations that Americans should increase their intake of fiber-rich foods. The reports are also in agreement in their conclusions that it is not clear if the relationship between fiber-rich foods and lower rates of cancer and other chronic diseases is the result of the fiber content of the foods or of other nutrients contained in these foods. Thus, virtually all recent dietary guidelines encourage the increased consumption of fiber-rich foods rather than fiber.

In its report "Diet, Nutrition, and the Prevention of Chronic Diseases," (Ref. 51), the World Health Organization stated that dietary factors are known to influence the development of a wide range of chronic diseases, including cancer, but the relationships between specific dietary components and cancer are much less well-established than those between diet and cardiovascular disease. The report noted that for populations in developed countries, some epidemiologists estimate that 30 to 40 percent of cancers in men and up to 60 percent of cancers in women are attributable to diet (Ref. 51). Although several studies demonstrated positive associations between the risk of colorectal cancer (primarily colon cancer) and dietary fat, the data relating dietary fiber to colorectal cancer are equivocal. The WHO report concluded that it is not clear whether dietary fiber is protective or whether the apparent effect is due to other food constituents (Ref. 51).

The 1990 Canadian Government document *Nutrition Recommendations—Report of the Scientific Review Committee* (Ref. 28) reviewed the literature on nutrient requirements and on various relationships between diet and disease. The goal of the document was to provide guidance in the selection of a dietary pattern providing essential nutrients, while reducing the risk of chronic disease (Ref. 28). With respect to cancer studies, the document noted that international epidemiologic studies show an inverse relationship between colon cancer mortality and fiber content of diets. The difficulty with epidemiologic studies, the document pointed out, is that they suffer from an inability to "disentangle the effect of the fiber content in the diet from the effect of fat and energy intake" which can influence the development of colorectal cancer (Ref. 28). The document concluded that various studies have provided inconsistent results and some have cast doubt on the beneficial effect of fiber. The Canadian recommendations are to increase present intakes of dietary fiber from a variety of carbohydrates and fiber-rich foods. The addition of large amounts of a single source of purified fiber to the diet was not recommended (Ref. 28).

In 1991, LSRO reviewed scientific studies that have become available since publication of its earlier report (Ref. 24). LSRO (Ref. 25) found no new evidence to support an association between increased intake of dietary fiber and decreased risk of cancer. The report concluded that it remains to be determined whether the observed effects of fiber are due strictly to fiber, to other components of fiber-rich food, to displacement of fat or calories from the diet by fiber, or to a combination of these (Ref. 25).

C. Review of the Scientific Evidence

1. Selection and Evaluation of Studies

a. *Selection of studies.* The criteria used to select pertinent studies required them to be publicly available in English, to provide a description of the study design and results that is adequate to permit an evaluation of the study, to include direct measurements or quantitative estimates of total dietary fiber intake as a single substance or as a component of foods, and to include direct measurement of risk of colorectal cancer (prognostic indicators, incidence, development, prevalence, or mortality).

Several types of human studies provide information on the role of dietary fiber in colorectal cancer. Correlational studies use grouped data to examine the relationship between dietary exposure and health outcome among populations. These studies do not examine relationships among individuals and have traditionally been regarded as useful for generating, rather than testing, hypotheses regarding diet-disease relationships. Analytic epidemiologic studies involve comparisons of individuals and have been regarded as providing the strongest type of observational evidence in human populations. In case-control studies, the relationship of an attribute (in this case,

a dietary component) to a disease is examined by comparing persons who already are diagnosed with cancer (cases) to persons without cancer (controls). A limitation of the case-control study is that diet is assessed in the cases after diagnosis, so that cases may unintentionally overestimate or underestimate dietary intakes of specific foods. Prospective cohort studies compare individuals who have been exposed to a risk factor to those who have not and observe individuals over time to determine if disease develops. In cohort studies, diet is assessed at the beginning of the study before cancer develops.

b. *Evaluation criteria.* FDA evaluated the results of studies in humans and animals against general criteria for good experimental design, execution, and analysis. The strengths and weaknesses of different kinds of epidemiologic studies and the methodologies for dietary assessment relevant to risk of chronic diseases, as well as suggestions on weighing of available evidence, are reviewed and discussed in the proposal on general requirements for health claims (published elsewhere in this issue of the **Federal Register**) and are also reviewed elsewhere (Ref. 30).

The criteria that FDA used in evaluating epidemiology studies included reliability and accuracy of the methods used in food intake analysis and measurement of disease endpoints, choice of control subjects, representativeness of subjects, control of confounding factors (for example, intake of fat and other nutrients; intake of vegetables), potential for misclassification of individuals with regard to dietary intakes, and presence of recall bias and interviewer bias.

The criteria that FDA used in evaluating studies in animals included whether components (for example, fiber) added to experimental diets were within physiological ranges of intake, whether there was control of confounding factors (for example, through use of isocaloric diets), whether the animal species was appropriate as a model for human carcinogenesis in response to dietary modification, and whether the numbers of animals used, the duration of exposures, the periods of observation, and methods used for assessment of disease endpoints, were appropriate.

FDA assessed the weaknesses and strengths of individual studies. FDA then assessed the strength of the overall evidence derived from the Federal Government reports, the other reports cited above, and the update of the scientific literature, using factors including the strength of associations, consistency of findings, specificity of reported associations, evidence for a dose-response relationship, and biological plausibility. FDA's conclusions reflect the strength, consistency, and the degree of concordance among results obtained from a variety of types of studies.

FDA also considered several factors identified by the NAS in its evaluation of the scientific basis for a relationship between intake of dietary fiber and cancer (Ref. 30). The NAS report cautioned that analysis of study results based on measures of total dietary fiber alone could be misleading because of the complex nature of the dietary substances subsumed under the term "fiber." In many studies, no quantitative data were given on the intake of total dietary fiber or of subcomponents of fiber. NAS (1989) also stated that in view of the importance of fat intake and total caloric intake, data from studies that are controlled for energy, fat, and other nutrients are the most useful. Fiber intake is correlated with caloric intake, which in turn is correlated with fat intake. Finally, the report cautioned that homogeneity of dietary fiber intake within a population may make it difficult to detect an effect of high fiber diet on incidence of cancer (Ref. 30).

2. Human Studies

The Federal Government reports and the other reports cited above noted that the effect of fiber-rich foods was best documented relative to risk of colorectal cancer. FDA reviewed all publicly available colon and rectal cancer studies in human subjects published from 1988 to the present. This review was undertaken to determine if more recent data provided additional evidence on an association between dietary fiber and risk of colorectal cancers, and if new results would alter the conclusions of the earlier reports.

a. *Correlational studies.* A brief summary of correlational studies relating to associations between dietary fiber and risk of colorectal cancer reviewed in "The Surgeon General's Report" (Ref. 47) and in reports by other scientific bodies is presented here. Many correlational studies have suggested a protective effect of dietary fiber against colon cancer (Refs. 24 and 47). Twenty-one of 24 correlational studies reviewed in "The Surgeon General's Report" (Ref. 47) identified an inverse association between intake of dietary fiber, cereals, or vegetables and occurrence of colon cancer. Three of the 24 studies showed no effect. One international study (Ref. 26) found an inverse association between colon cancer and total dietary fiber and reported a protective effect of cereal fiber, even after adjustment for intake of fat or meat. Some of these studies also showed correlations between intake of other nutrients and colon cancer. Thus, while patterns of eating foods high in fiber showed good correlation with low colon cancer rates, other dietary components might also be influencing this association (Ref. 47).

Two recent studies (Table 1) have correlated colorectal cancer mortality with population-based dietary intake data. Rosen et al. (Ref. 37) correlated colon cancer mortality rates from 1969 to 1978 with estimates of dietary intake of fiber for 24 counties in Sweden. Dietary fiber intake was calculated from household food expenditure data (excluding foods eaten outside the home) for 1978. Results showed a strong negative correlation (inverse relationship) between dietary fiber and colorectal cancer in both men ($r=-0.75$) and women ($r=-0.67$) ("r" means simple correlation coefficient), and this association was not altered by controlling for fat intake. Rosen et al. (Ref. 37) observed similar correlations for high-fiber breads. No effects of vegetable consumption on colorectal cancer were observed (Ref. 37).

Daily per capita total dietary fiber intake was estimated to be 12 g based on expenditure data. Regional data showed a high intake of milk and fat as well as fiber in areas with low mortality rates from colorectal cancer. A major limitation of correlational studies is that dietaty intakes are not necessarily assessed in the individuals who develop the disease under investigation. This limitation and regional differences in dietary intakes may explain why high intakes of fat, fiber, and milk were associated with low mortality rates from colorectal cancer in the study by Rosen (Ref 37).

Morales Suarez-Varela et al. (Ref. 29) (Table 1) undertook a correlational study of diet and rectosigmoid cancer in Spain. The investigators correlated standardized mortality and morbidity data from rectal and sigmoid colon cancer in 50 Spanish provinces with dietary fiber (type unspecified) consumption estimated from food composition tables of the National Statistical Institute. Consumption of vegetable fats, butter and pork lard, total animal fats, and fiber showed no correlation with provincial morbidity and mortality due to rectal cancer. Sex-specific standardized morbidity ratios for men showed a modest positive correlation (0.3344; $p<0.01$) of fiber consumption with rectosigmoid colon cancer morbidity. These observations are difficult to interpret because the

study combined data from rectal and lower (sigmoid) colon cancer cases.

b. *Case-control studies.* In several recent case-control studies, patients with colon cancer and matched controls were interviewed about previous fiber intake (Table 2). Kune et al. (Ref. 21) (Table 2), in a study of 715 colorectal cancer cases and controls, analyzed data on total fiber, vegetable fiber, and fruit fiber intake. Dietary information covering the previous 20 years was obtained from subjects by interview. Although uncontrolled analysis for total fiber, vegetable, fruit, and cereal fiber gave a negative association with colorectal cancer, the effect was removed when micronutrients, fats, and energy were controlled. By examining interaction effects, the combination of high fiber intake and high vegetable intake was found to be protective, although neither was independently protective. The source of the fiber (cereal, vegetable, or fruit) did not alter the interaction. The types of fiber involved (soluble or insoluble) were not identified (Ref. 21).

Tuyns et al. (Ref. 44) (Table 2) conducted a case-control study of 453 colon cancer patients, 356 rectal cancer patients, and 2,851 population-based controls in 2 Belgian provinces. Cases were asked about their usual food intakes over 1 week before the onset of illness and controls at the time of interview. Only 50 percent of the case series were successfully interviewed. Logistic regression analysis was used to estimate the relative risk of colon and rectal cancer, controlling for age, sex, province, total calories, and other nutrients. Dietary fiber intake was significantly negatively associated with both colon and rectal cancer (i.e., the higher the fiber intake, the lower the incidence of these cancers), and there was a negative linear trend indicative of an intake response (Ref. 44). This trend was not affected by adjustments for calorie intake. However, the low response rate of the cases (50 percent) may have introduced selection bias and substantially reduces the confidence that can be placed in the results.

West et al. (Ref. 48) (Table 2) studied dietary intake in 231 colon cancer cases from the Utah Cancer Registry and 391 controls identified by random digit dialing. A stratified random sample of control individuals within the selected households was chosen to reflect sex, age within 5 years, and county of residence of cases. Food intake was assessed by a food frequency questionnaire for the 2 to 3 years prior to the interview. Interviews were completed for 71 percent of cases and 74 percent of controls. Odds ratios and multiple logistic regression analysis were used to estimate the risk of colon cancer controlling for age, body mass index, and energy intake, but not for other dietary factors. Increased crude fiber intake was associated with a decreased risk of colon cancer for both males and females. Ninety percent confidence intervals were used in the statistical analysis and this finding was significant at the 0.10 level.

A detailed analysis of dietary fiber components was undertaken in a case-control study in western New York of 428 colon cancer cases, 422 rectal cancer cases, and neighborhood controls (Refs. 9 and 10) (Table 2). Cases were identified from hospital pathology reports. Sixty-five percent of colon cancer patients, 54 percent of rectal cancer patients, and 53 percent of eligible controls were interviewed regarding frequency of consumption of foods for 1 year prior to onset of symptoms. Total dietary fiber was classified by source from grain, or fruit, or vegetables, and for each of these, the soluble and insoluble components were identified. Insoluble fiber from each source (grain, fruit, or vegetables) was further classified as hemicellulose, cellulose, or lignin. Conditional logistic regression analysis, with adjustment for fat intake, was used to estimate the impact of total fiber and each of five fiber components from grains and fruit or vegetables on risk of colon and rectal cancer. Separate analyses were performed for males and females. Reduction in risk of colon cancer was associated with intake of grain fiber in both males and females and with fiber from fruit or vegetable sources for males only. Insoluble grain fiber was more strongly associated with reduction in risk of colon cancer than soluble fiber. Analysis of risk of rectal cancer showed a protective effect of fruit or vegetable fibers but not grain fibers. There were no differences in the effects of soluble and insoluble fiber. However, the analysis did not control for other components of fruits and vegetables that might affect cancer risk. Furthermore, the low response rates for cases and controls may introduce selection bias.

Wohlleb et al. (Ref. 50) (Table 2) conducted a small case-control study of colorectal cancer (43 patients and 41 controls) in men at a U.S. Veterans Administration hospital. Demographic traits, medical history, occupational history, use of alcohol and tobacco, and other information were obtained by questionnaire that also collected data about weekly intakes of 55 food items (that is, current diet was surveyed). Consumption of cauliflower (a cruciferous vegetable) was significantly associated with fewer cancers in this study. Consumption of rolled oats appeared as a significant protective factor against colorectal cancer, and other high-fiber foods (wheat bran and unpeeled apples) were apparently protective (Ref. 50).

A case control study conducted in Stockholm, Sweden, involved 452 subjects with colon cancer, 268 subjects with rectal cancer, and a population based control group (Ref. 8) (Table 2). Dietary data for the previous 5 years was obtained by a food frequency questionnaire. Interviews were completed for 76 percent of cases and 87 percent of controls. A protective effect of high fiber intake against colon cancer was found in men (RR = 0.5) but not in women (RR = 1.2). Fiber appeared to be protective against rectal cancer in both sexes (RR for all subjects = 0.5). The data were analyzed controlling for year of birth and protein intake but not for other nutrients. There was an interaction effect observed between protein and fiber intake such that fiber had a greater protective effect in those consuming a low protein diet.

A case-control study performed in Utah (Ref. 40) (Table 2) involved 231 colon cancer cases and 391 controls. Subjects were interviewed about diet for the 2 years prior to diagnosis. Consumption of fruits, vegetables, and grain was estimated by a food frequency questionnarie. Fiber intake was calculated from several food tables, and in some cases actual analysis of foods was performed to allow assessment of the effects of chemically-defined fiber fractions. Body mass index, caloric intake, membership in the Mormon church, and age were controlled for by statistical adjustment. The effect of fiber varied with the chemical type and food source. Intake of fruits and vegetables was negatively related to risk of colon cancer in males and females. Intake of grain fiber was not protective. The effects of neutral detergent fiber or dietary fiber as determined by the method of Bitner were weak and inconsistent. Fiber effects, when detected, were usually of greater magnitude in males. This study is one of the few to examine the effects of several analytically defined fiber fractions. The results suggest that fibers from different food sources have different effects.

Lee et al. (Ref. 23) (Table 2) conducted a case-control study of 132 colon cancer cases and 71 rectal cancer hospital cases in Singapore. Dietary information was obtained about usual diets consumed 1 year prior to the interview.

Intakes of cruciferous vegetables and a high intake of vegetables relative to meats were generally protective against colorectal cancer. Fiber was protective for rectal cancer (OR=0.46; $p<0.05$) but not for colon cancer. Protective effects were reported for cruciferous vegetables (OR=0.50<0.01). The authors urged caution in interpreting their data for rectal cancer, however, because of the small number of cases.

One study examined the dietary patterns of patients with colonic polyps (considered a precursor lesion to colon cancer) and of individuals without polyps. Hoff et al. (Ref. 15) (Table 2) assessed dietary intake from 5-day food records in a case-control study utilizing patients participating in endoscopic screening for colonic polyps. Nutrient intake of patients with and without polyps was compared. Patients were not aware of their polyp status when they completed the food intake records. Results revealed that patients with large polyps consumed significantly less total dietary fiber and less total carbohydrate than patients without polyps. Intake of vitamin C and cruciferous vegetables did not differ significantly among patients with or without polyps, although patients with multiple polyps had a significantly lower intake of cruciferous vegetables and vitamin C compared to patients with only a single polyp. Assessment of diets 1 to 2 years or more prior to onset of symptoms would have provided more useful information.

Benito et al. (Ref. 4) (Table 2) conducted a case-control study of 286 colorectal cancer patients, 295 age and sex-matched community controls, and 203 hospital controls on the Spanish island of Majorca. The participants were given a food frequency questionnaire covering the 6 months prior to the interview. Consumption of high-fiber vegetables was found to have no effect on the risk of colorectal cancer. No data on total fiber or its components were provided. Slattery et al. (Ref. 41) conducted a case-control study correlating diet prior to diagnosis with survival time in colon cancer patients. Dietary information for the 2 to 5 years prior to diagnosis of colon cancer was collected by interview. The highest quartile of fiber intake was associated with decreased survival time.

c. *Prospective studies.* In two recent prospective studies, dietary intakes of individuals were estimated at baseline by mailed questionnaire and then individuals were followed over time for occurrence of disease. Willet et al. (Ref. 49) (Table 3) in a study involving 6 years of followup of 88,751 female nurses (ages 34 to 59 years) found no evidence of a protective effect of intake of total crude fiber on colon cancer. A high intake of crude fiber from fruit, but not from vegetables or cereal, showed a significant protective effect but this effect was not statistically independent of intake of red meat.

Heilbrun et al. (Ref. 13) (Table 3) conducted a nested case-control study of 8,006 Japanese-American men in Hawaii, with 361 controls, 102 cases of colon cancer, and 60 cases of rectal cancers. Dietary intakes of crude fiber were based on a single 24-hour recall collected between 1965 to 1968. Cancer cases consumed an estimated 11.4 to 12.1 g per day of crude fiber while controls consumed 11.6 g of crude fiber per day. Proportional hazards models adjusted for age, and for alcohol intake in the cases of rectal cancer, were used to estimate the relative risk of colon and rectal cancer. The models included all micronutrients, fat, calories, saturated fat, protein, cholesterol, and carbohydrates. Fiber was protective in the low fat group when the cohort was divided into two groups at the median level of fat intake of colon cancer cases. When fat intake was less than 61 g per day, risk of colon cancer decreased as consumption of fiber increased ($p<0.042$).

d. *Meta-analysis of epidemiologic studies.* Trock et al. (Ref. 43) performed a thorough review with reanalysis of data from all English-language epidemiologic studies concerning colorectal cancer and fiber, vegetables, grains, or fruit published from 1970 through 1988. The review included 23 case-control studies, 7 international correlation studies, 8 within-country correlation studies, 2 cohort studies, and 3 time-trend studies. Trock et al. (1990) made an aggregate assessment of the strength of evidence from numerous observational epidemiologic studies and meta-analysis of data from 16 of 23 case-control studies. Both types of analyses indicated that the majority of studies give support for a protective effect of fiber-rich foods against colorectal cancer. Risk estimates based on vegetable consumption were only slightly more convincing than those based on estimates of fiber intake. The authors noted that the data do not permit discrimination of the fiber and nonfiber effects of vegetables (Ref. 43).

e. *Intervention studies.* DeCosse et al. (Ref. 7) conducted a long term, randomized intervention study aimed at reducing rectal polyp recurrence in patients with familial polyposis. Adults patients (n=58) having undergone previous total colectomy for familial polyposis were given daily supplements of vitamins C and E alone or with wheat bran, and rectal polyp number and size was assessed repeatedly over a 4-year period. Fiber appeared to reduce mean polyp size over time, especially if total intake of fiber was calculated as dietary sources plus fiber supplement. Thus, the authors concluded that benign large bowel neoplasia was inhibited by intakes of grain fiber supplements greater than 11 g per day. It is not known whether the results of this study can be applied directly to the much more common clinical situation of sporadic colonic polyps.

f. *Mechanistic studies.* The mechanisms by which fiber may affect colonic carcinogenesis are unknown. Proposed mechanisms include effects of fiber to:

(a) Dilute fecal bile acids which may have growth promoting effects on small adenomas;

(b) Reduce fecal mutagenicity;

(c) Alter fecal bulk;

(d) Increase fecal transit time;

(e) Alter colonic mucin;

(f) Change fecal pH; and

(g) Alter colonic cell proliferation.

Newer hypotheses have focused on the role of microbial fermentation in cancer prevention (Ref. 22). A number of studies have been performed in attempts to test which of these potential mechanisms may affect tumorigenesis.

FDA reviewed a number of studies that examined hypothesized risk factors for colon cancer such as cell turnover, fecal bile acids, and fecal mutagens. Such studies are helpful in determining possible mechanisms of action for effects of fiber or fiber-rich foods on carcinogenesis. Fiber type and amount can be carefully controlled in animal and human mechanistic studies. As a result, it should be possible to distinguish effects of fiber from effects of other components of fiber-rich foods.

Reddy et al. (Ref. 35), in a study involving supplementing the diet with a mixture of high-fiber oat and whole wheat bread, found a significant decrease in fecal secondary bile acid concentration and decreased fecal mutagenicity with increased fiber intake in the form of high-fiber bread.

Reddy et al. (Ref. 34), in a dietary intervention study, instructed subjects to eat a high fiber, low fat, low meat diet, similar to the "Pritikin"-type diet. The dietary intervention increased stool weight and decreased bile fecal acid concentration (effects that are thought to be protective against colon carcinogenesis). The interpretation of the study was complicated by significant weight loss in the subjects

and major dietary changes other than alterations in dietary fiber. The study design did not use a contemporaneous control group and did not attempt to crossover treatments.

In a well-designed study, Reddy et al. (Ref. 33) fed wheat bran, cellulose, or oat bran to human subjects in a randomized crossover design. Both wheat bran and cellulose reduced fecal mutagenicity, fecal bile acid concentration, and fecal neutral sterol concentration. These are all considered positive changes toward reducing colon cancer risk. Oat bran, however, did not significantly alter these parameters compared to those measured with the baseline "normal" diet.

Allinger et al. (Ref. 3) instructed subjects to increase their intake of fruits, vegetables, and grains, eliminate meat and eggs, and consume only fermented, rather than fresh, dairy products. The change in diet was conducted in three "shifts" (March, May, and August) to attempt to control for seasonal variability. The total dietary change resulted in increased fecal weight and decreased soluble fecal deoxycholic acid (both thought to be favorable changes for reduced risk of colon cancer). Because of the combined dietary approach, it cannot be determined whether the additional fiber or the other changes in the diet were responsible for the observed alterations in the fecal parameters.

Johansson et al. (Ref. 18), in another study utilizing the same subjects and diets, as Allinger et al. (1990), examined changes in fecal bacterial enzyme activities in response to the dietary modifications. The dietary change decreased the activity of three fecal bacterial enzymes considered to be important in colonic carcinogenesis. Most of the effect was apparently the result of dilution by increased stool volume. Moreover, the importance of these bacterial enzymes in the development of human colon cancer is unknown. It cannot be determined whether the additional fiber or the other changes in the diet were responsible for the observed alterations in the fecal parameters.

Alberts et al. (Ref. 2) examined rectal cell proliferation in a trial of wheat bran supplementation (13.5 g per day) in patients in whom colons were removed for treatment of colon cancer. Seventeen patients (aged 54 to 70 years), at high risk of recurrent colorectal cancer, participated in the 8-week study. Rectal cell proliferation was assessed by two methods both pre- and post-diet intervention. One method of assay showed a significant mean decrease in rectal cell proliferation after 2 months of wheat bran supplementation while the other showed no change.

Kashtan et al. (Ref. 19) found that 100 g of oat bran decreased fecal pH significantly in normal volunteers, while lesser quantities of oat bran did not produce significant reductions in fecal pH. Psyllium and wheat bran did not affect fecal pH. The importance of fecal pH in colon cancer has not been determined.

In a study by Friedman et al. (Ref. 11), human colonic cells were incubated in vitro with psyllium or bile salts. Small decreases in the cytotoxicity of the bile salts were noted with the addition of psyllium, and other alterations in cell growth were seen when various short chain fatty acids (products of bacterial digestion of fiber in the large intestine) were added. However, adding ungraded psyllium to a cell culture is not reflective of the bacterial metabolism of this material which occurs in the colon in vivo. No rationale is provided to relate the concentrations or relative proportions of short chain fatty acids added to the culture to the products of actual bacterial digestion of psyllium in vivo. Thus, the in vitro conditions in this study may not be physiological.

3. Animal Studies

As mentioned previously, most laboratory animal studies of dietary fiber and cancer have focused on colon cancer. Results of numerous animal studies are reviewed by LSRO (Ref. 24), in The Surgeon General's Report. (Ref. 47), and in "Diet and Health" (Ref. 30). Recent reviews include those (Refs. 17 and 32).

Effects of dietary fiber on colon carcinogenesis in animals are frequently studied following exposure of the animals to a compound such as 1,2-dimethylhydrazine (DMH) which is known to be carcinogenic to the colon. The animals are then fed varying amounts and types of dietary fibers and subsequent effects tumorigenesis are observed. The carcinogen is usually given weekly via a tube into the stomach or injection for a 5- to 10-week period. Tumors begin to develop within 2 to 3 months following completion of carcinogen treatment.

The 1987 LSRO (Ref. 24) report notes that studies using animal models to examine the role of various types of dietary fiber in the development of carcinomas of the colon provide conflicting results. One of the factors that has a major effect on the results of carcinogenesis studies is the type of dietary fiber fed to the animals. Many studies have shown that not all fiber types reduce experimental colon cancer. Dietary soybean bran and rice bran showed no effect on DMH-induced colon carcinogenesis in rats, while oat bran had an enhancing effect. Corn bran had either an enhancing effect or no effect on colon carcinogenesis, while 10 percent guar gum was shown to enhance tumor development. Most studies with wheat bran show an inhibitory effect. The 1987 LSRO (Ref. 24) report states that both the physical and chemical properties of a fiber source are probably important in determining its effects. Of all fiber types studied, the authors considered wheat bran to have the most consistent inhibitory effects on colonic tumor development.

Many factors besides the type of fiber fed were noted to affect the outcome of these studies, including the type and dose of carcinogen given, the sex and strain of animal, the total duration of the study, and whether the fiber was fed during the initiation phase (while carcinogen is being given) or during promotion (after completion of carcinogen treatment).

"The Surgeon General's Report" (Ref. 47) noted that wheat bran was found to be protective in most but not all animal studies. Results of animal studies of fibers such as corn bran, rice bran, oat bran, pectin, and guar gum were much less consistent. Some studies showed a protective effect, more tended to show a tumor-enhancing effect, and others showed no effect. "The Surgeon General's Report" (Ref. 47) concluded that the relevance of these animal models to human cancer needs to be determined.

The NAS, in "Diet and Health" (Ref. 30) cited a diversity of results (protection, enhancement, no effect) for nonhuman carcinogenesis studies of various types and amounts of fiber. The report concluded that the type of fiber is very important in determining its effects on colon carcinogenesis. NAS (Ref. 30) also noted that wheat bran has the most consistent inhibitory effect.

Animal studies published since 1987 in which animals were fed defined diets containing cellulose, wheat bran, or psyllium are reviewed briefly below.

Roberts-Anderson et al. (Ref. 36) fed 10 percent cellulose, 10 percent psyllium, or a fiber free diet to rats both during and after administration of a chemical carcinogen. Both fiber treatments reduced tumor incidence. Rats in the psyllium group gained considerably less weight than control rats, and the duration of the study was significantly shorter than most published tumorigenesis studies. The number of rats exposed to the carcinogen was also smaller than usual for studies of this type.

Heitman et al. (Ref. 14) fed rats 0, 5, or 15 percent cellulose during the phases of initiation or promotion or both. Cellulose at 5 or 15 percent showed statistically significant protective effects if fed during both initiation and promotion. Other combinations of cellulose feeding (promotion only, etc.) produced reductions that were not statistically significant. The authors correlated the antitumor effects of cellulose with its ability to inhibit DMH-induced cell replication during initiation. This study suggests a protective effect for cellulose when fed during both initiation and promotion.

Three recent studies evaluated the effect of wheat bran on colon carcinogenesis. Calvert et al. (Ref. 6) fed 10 percent wheat bran or wheat bran with bile salts added (sufficient to eliminate its effects on bile salt dilution) to rats during the promotion phase, after they had been exposed to the chemical carcinogen DMH. Wheat bran consistently reduced tumor incidence and multiplicity in this study. Added bile salts did not diminish this effect, suggesting that bile salt dilution is not the mechanism of the observed antitumor effect. Tatsuta et al. (Ref. 42) noted no effect of wheat bran on tumor development in their study. Wheat bran was fed during both initiation and promotion. Sinkeldam et al. (Ref. 39) fed 9 or 17 percent wheat bran to rats on low, medium, or high fat diets. Diets were consumed during both initiation and promotion. The 17 percent wheat bran diets eliminated the tumor enhancing effect of increasing levels of fat. If fat levels were moderate or low, 9 percent wheat bran enhanced tumorigenesis, while 17 percent wheat bran was inhibitory.

Thus, three recent studies with wheat bran report inconsistent effects on colon carcinogenesis. Differences in the timing of the feeding of wheat bran (promotion phase only versus initiation and promotion phases) or fat levels may partly explain these inconsistencies.

4. Other Relevant Information

Concerns have been raised about potential risks of ingesting isolated or purified forms of fiber (Ref. 24, 25, and 52). Side effects and possible adverse health effects of high intakes of dietary fiber have also been hypothesized by NAS (NAS, 1989). Excessive consumption of fiber supplements may result in more intestinal problems or poor absorption of trace minerals than would be expected from a high-fiber diet (Ref. 25). Safety concerns about more novel sources of fiber (e.g., gums and isolated sources of fibers) when consumed in large amounts or when consumed in nonfood forms have also been raised (Ref. 52). However, high dietary intakes of foods with naturally-occurring fiber have generally not been found to have adverse health effects (Ref. 24 and 30).

5. Conclusions

Federal Government documents (Ref. 47) and the other referenced reports from recognized scientific bodies (Refs. 24, 25, and 30) concur that the evidence for a protective effect of dietary fiber in colon carcinogenesis is inconclusive. However, they do note the association of dietary patterns high in plant foods to reduce risk of cancer and other chronic diseases.

Of two recently reported correlational studies, one compared colorectal cancer mortality in Sweden with population-based dietary fiber intake data and found a strong negative correlation between intake of dietary fiber and colorectal cancer mortality in men and women, Rosen et al. (Ref. 37). In a second study, Morales Suarez-Varela et al. (Ref. 29) found no correlation between fiber intake and rectosigmoid cancer morbidity or mortality among 50 Spanish province Spain.

Dietary fiber is extremely heterogenous in nature (Refs. 12 and 24) and fiber-rich foods differ significantly in the amounts and types of fiber components they contain. The limited amount of analytical data on dietary fiber and various components of dietary fiber have impeded research on its health effects (Ref. 22).

Human studies on effects of dietary fiber intake and risk of cancer of the colon and rectum have differed in classification of dietary fiber (i.e., source, type, components) and in measurement of dietary intake (e.g., 24-hour recall, food frequency). The results of these studies have also differed. Of two recent case-control studies that were adequately controlled for other known components of fruits and vegetables, one study, Kune et al. (Ref. 21) reported no effect of dietary fiber per se but found an interaction such that those consuming diets high in fiber and vegetables experienced a reduced risk of colorectal cancer. Tuyns et al. (Ref. 44) reported a protective effect of dietary fiber and an intake response relationship.

Three other recent case-control studies did not control for micronutrients in vegetables and fruits. The results of these studies were inconsistent. West et al. (Ref. 48) reported an association of crude fiber with reduced risk of colon cancer. Freudenheim et al. (Refs. 9 and 10) observed no association of total fiber with colon cancer, but grain fiber was protective in men and women, and fruit and vegetable fibers were protective in men only. The same study showed fruit or vegetable fiber to be protective for rectal cancer (statistically significant only in men) regardless of soluble or insoluble components. In contrast to the results reported for colon cancer, grain fiber consumption was not associated with risk reduction in rectal cancer. De Verdier et al. (Ref. 8) reported that fiber was protective in men only, but an interaction was observed such that a low protein and high fiber diet led to a reduction in risk of colon and rectal cancer. Because none of these studies controlled for nutrients or other components in fruits and vegetables, it is not possible to determine if observed effects were due to fiber or to nonfiber components of fruits and vegetables.

Among two recently completed prospective studies, Willet et al. (Ref. 49) reported no effect of crude fiber or components when consumption of red meat was controlled. Heilbrun et al. (Ref. 13) reported no effect of dietary fiber on colon or rectal cancer. However, fiber was protective in those subjects with a fat intake below the median for the group as a whole.

A number of studies have examined effects of dietary fiber on possible risk factors for colorectal cancers. Such studies have examined effects of specific types of fibers on hypothesized risk factors for colorectal cancer. Generally favorable effects of some types of fibers on such factors have been reported. The actual risk factors for colorectal cancer are still incompletely understood, however. Thus, the significance of favorable effects produced by fiber feeding on particular parameters such as secondary bile acid concentration, fecal mutagenicity, fecal weight, fecal deoxycholic acid, and activity of fecal bacterial enzymes is not clear at this time. Additional studies are needed to establish which, if any, of these factors affect the development of human colon cancer.

Thus, evidence that has become available since the publication of the Federal Government and the other major reviews by recognized scientific bodies does not provide a basis for altering the conclusions of these documents which note a reduced risk for colon cancer with diets high in fiber-containing foods but not for fiber in isolation.

Results of studies of colon carcinogenesis in animals must be interpreted cautiously. Colon cancer is induced in animals by relatively

infrequent exposures to large doses of a known, potent carcinogen, while in human colon cancer, carcinogen exposure is presumably long-term, possibly continuous, and arises from as yet unidentified carcinogens. In animal studies, different types of fiber produce widely varying results. Animal sex, strain, carcinogen dose, and other aspects of study design profoundly influence the results. Fiber in general shows no consistent protective effect. Wheat bran shows the most consistent protective effect, but even among wheat bran studies results are not completely consistent.

Human studies are just beginning to examine effects of specific types of fiber. Data currently available, however, are insufficient to conclude whether fiber itself, specific components of fiber, or some other components of diets rich in fruits, vegetables, and grains are the factors responsible for the risk reduction observed in some studies. Nor has it been established what type or amount of fiber is necessary for a protective effect. The mechanism of fiber's effects, if any, is also unknown. For all of these reasons, a specific relationship between dietary fiber and decreased risk of cancer has not been demonstrated. However, a relationship between vegetables, fruits, and grains that contain fiber and other nutrients and a reduced risk for cancer has been demonstrated.

III. Tentative Decision Not To Propose a Health Claim Relating Dietary Fiber to Decreased Risk of Cancer

FDA limited its review of the scientific evidence relating ingestion of dietary fiber and cancer to the topic of dietary fiber and risk of colorectal cancer. This limitation was deemed appropriate because the great majority of epidemiologic and intervention studies have focused on colon cancer, as have virtually all animal studies in this area. The strongest support and largest volume of evidence for a possible protective effect of fiber-rich diets is for colon and rectal cancers (colorectal cancers), the second leading causes of cancer deaths in the United States (Ref. 46). Relationships between dietary fiber and risk of cancer at other sites (for example, breast, stomach, endometrium, and ovaries) have been less extensively examined but are currently the focus of considerable research effort (Refs. 47, 30, and 25).

FDA has tentatively concluded, based on the totality of the evidence, that there is not a sufficient basis to authorize a health claim for dietary fiber and reduction in risk of cancer. Numerous human and animal studies have examined the possible role of dietary fiber intake in reducing the risk of developing colon cancer. Most correlational and many (but not all) case-control studies show that diets high in fiber-containing foods (whole grains, fruits, and vegetables) are associated with a reduced risk of colorectal cancer. Prospective epidemiologic studies are few in number and give mixed results. Animal studies indicate that certain types of dietary fiber are important in modulating the effects of chemical carcinogens.

There is substantial evidence that fiber-rich foods and diets high in fiber-rich foods, including whole grains, fruits and vegetables, are associated with reduced risk of colorectal cancer. These diets differ, however, in levels of many nutrients and in types of dietary fiber, making it difficult to ascribe the observed nutrient and disease relationship to a single nutrient. Overall, the available data are not sufficient to demonstrate that it is the total dietary fiber, or a specific fiber component, or specific vitamins and minerals (singly or interactively) that are related to reduction of cancer risk.

A major limitation in designing and evaluating research studies has been the need for better defined measures of dietary fiber and standardized descriptions for source, type, and amount of dietary fiber (Ref. 24). Dietary fibers are a heterogeneous family of compounds that vary considerably in chemical composition, physical characteristics, and biological effects (Refs. 12 and 24). Processing of foods and fiber sources may also alter the inherent characteristics of the fiber (Ref. 24). The commonly used analytical methodologies often do not detect many of the characteristics that vary among fibers and that may be related to biological function (e.g., particle size, chemical composition, or water-holding capacity) (Refs. 12 and 24). Analytical methods also do not differentiate between source or type of fiber. This lack of ability to detect many of the differences that exist among fibers and the general lack of clear evidence as to the mechanisms of action of fibers have raised questions as to the ability of commonly used analytical measures of dietary fiber to adequately predict biological actions of specific fibers (Refs. 12 and 24).

Another problem in evaluating the relationship of dietary fiber intakes to risk of chronic diseases such as cancer is the lack of reference food composition data on the fiber content of foods. Consequently, most human studies have described dietary intakes in terms of amounts of fruits, vegetables, or other food groups rather than as total dietary fiber intakes; or have used measures of the crude fiber content of foods rather than total dietary fiber to estimate fiber intakes. Not only do measures of crude fiber variably underestimate intakes of total dietary fiber, but they also are not necessarily reflective of the various combinations of types of fiber normally present in foods. The seriousness of this limitation varies by type and objective of study, but inappropriate and inadequate estimates of dietary fiber intakes can limit the ability to detect a fiber/cancer relationship in some studies. This limitation affects, then, the ability to link dietary fiber intakes to cancer risk.

In summary, the currently available scientific evidence is not sufficiently conclusive or specific for fiber per se to justify use of a health claim relating intake of dietary fiber to reduced risk of cancer. Federal government (Refs. 25 and 47) and other reviews by recognized scientific bodies (Refs. 24, 25, 30, and 31) are consistent in agreeing that it is difficult to separate the effects of fiber from those of other dietary components present in high fiber foods or in dietary patterns high in plant food. As noted above, the evidence that has become available since publication of these reports is consistent with these conclusions and is, therefore, not sufficient to alter the earlier conclusions. Thus, FDA has tentatively concluded, based on the totality of the scientific evidence, that there is not significant scientific agreement among experts qualified by training and experience to evaluate such a relationship, as to the independent and specific role of dietary fiber or fiber components in reducing the risk of cancer, particularly colon cancer.

Virtually all recent dietary guidelines for Americans have encouraged the increased consumption of fiber-rich foods, including whole grain cereals, fruits, and vegetables. This recommendation is also consistent with available scientific evidence which shows that changes in dietary patterns can play a significant role in reducing risk of colorectal cancer, other cancers, and other chronic diseases (Refs. 30, 47). FDA has supported and continues to support these recommendations and to encourage dietary guidance consistent with the recommendations.

This raises a dilemma, however, for which FDA is requesting comment. To encourage and help consumers to meet dietary guidance recommendations, it would be useful to have appropriate dietary information at point of purchase. The use of health claims on foods

(including dietary supplements) to inform consumers of these recommendations, however, is problematic because it is not clear what qualifying and other criteria are necessary to adequately define eligible foods for such a health claim. As described in companion documents on "General Principles for Health Claims" and in requirements for "Mandatory Nutrition Labeling," the fiber content of foods (including dietary supplements) as measured by the Association of Official Analytical Chemists method for dietary fiber is proposed to serve as the basis for nutrition labeling of fiber content and, consequently, for determining whether foods and supplements qualify for health claims. Yet as discussed above, the correspondence between analytical fiber content and biological responses is not established. Thus, health claims that derive from this basis could be misleading. Congress, in the 1990 amendments, specified that FDA evaluate nutrient and disease relationships. Dietary fiber was specified as one nutrient for evaluation. Yet, FDA has tentatively concluded that the available evidence that is supportive of food patterns containing fiber-rich foods cannot be extrapolated to a specific fiber effect at this time.

Given the public health significance of cancer, specifically colon cancer, and given the general dietary guidance to increase consumption of fruit and vegetables and whole grain products which are rich sources of dietary fiber and other nutrients, FDA is requesting comments on how to best inform consumers of these issues.

Specifically should the agency permit a claim on the label or in labeling such as: "Diets high in fruit, vegetables, whole grains are associated with a reduced risk of cancer of the lower bowel and cardiovascular disease;" or alternatively "Research has shown that populations who consume diets that contain several servings each of fruit, vegetables, and whole grains have a decreased risk of certain forms of cancer and cardiovascular disease;" or "Choose diets with plenty of fruit, vegetables, and whole grains to help lower your risk of cardiovascular disease and certain forms of cancer." If such statements should be permitted, what criteria should be used to identify foods that are eligible for such statements? For example, should such statements be limited to fresh fruit, vegetables, and milled whole grains, or should processed foods derived from these producers be also included? What measure should the agency adopt to assure that consumers are not misled as to the benefit of consuming a specific product?

The use of such claims on fruit, vegetables, and whole grains raises the issue of authority to permit claims for food as well as nutrients. FDA specifically requests comments on whether it has the authority and should allow health claims on foods as well as nutrients. FDA also requests information on how to develop regulatory criteria for such a program. If FDA were to permit such claims, what qualifying and disqualifying criteria should be used to determine eligibility for a claim, and what methods or criteria should be used for regulatory monitoring and compliance? Additionally, FDA requests comments on what criteria could be used to develop a health claim for foods that would provide truthful and not misleading messages to consumers that changes in dietary patterns are related to reductions in cancer risk.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VI. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore under the Federal Food, Drug, and Cosmetic Act, and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR Part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.71 is amended by adding paragraph (a) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(a) Dietary fiber and cancer (insert cite and date of publication in the **Federal Register** of the final rule).

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

TABLE 1.—DIETARY FIBER AND COLORECTAL CANCER: CORRELATIONAL STUDIES

Study	Type and location	Design	Methods	Results	Comments
Rosen et al., 1988 (Ref. 37).	Correlational Sweden	Cancer mortality rates from 1969–1978 and dietary practices were studied in 24 countries.	Dietary fiber was calculated based on food expenditures for 1978. Population providing food expenditure data was a random sample of 5,760 households. All food expenditures for 2 weeks were recorded.	High intake of cereal fiber was protective against colorectal cancer for both males, females. A negative correlation between milk consumption and colorectal cancer was found.	Food eaten in restaurants and food wastage were not accounted for. Estimates were based on food expenditure rather than on consumption.
Morales Suarez-Varela et al., 1990 (Ref. 29).	Correlational, Spain	Correlated mortality rates from rectal cancer (including sigmoid colon) with dietary practices, including dietary fiber intake.	Study covered period from 1977–1985. Consumption of various diet components obtained from Natl. Statistics Institute publications. Components examined were total lipids, animal fats, vegetable fats, butter and pork lard, margarine, fiber, and alcohol.	No significant correlations were established between animal fat, vegetable fat, total lipids, or fiber and morbidity and mortality.	Data for rectal and sigmoid colon cancer were combined.

TABLE 2.—DIETARY FIBER AND COLORECTAL CANCER: CASE CONTROL STUDIES

Study	Type and Location	Subjects	Methods	Results	Comments
Benito et al., 1990 (Ref. 4).	Case control, Majorca	286 cases of colon cancer (including rectal cancer); 295 community controls matched for age, sex; 203 hospital controls.	Subjects given food frequency questionnaire covering 6 months prior to interview.	Increased risk of colon cancer found for higher consumption of fresh meats; protection associated with high intake of cruciferous vegetables. Fourfold increase in risk of colorectal cancer found for high consumption of fresh meat, dairy products, and cereals combined with low intake of cruciferous vegetables.	The study examined effects of foods rather than fiber.
De Verdier et al., 1990 (Ref. 8).	Case control, Sweden	452 cases of colon cancer, 268 cases of rectal cancer, 624 controls matched for age.	Dietary data obtained by food frequency questionnaire covering previous 5 years. Method of fiber calculation was not specified.	Those consuming high fiber, low protein diets had lowest risk of colorectal cancer. Fiber was protective against colon cancer for males. Fiber was protective for rectal cancer for both males and females.	Data analysis was not controlled for micronutrients or fats.
Freudenheim et al., 1990 (Ref. 9).	Case control, Western New York.	428 colon cancer cases (223 males, 205 females); 422 rectal cancer cases (145 males, 277 females); 428 community controls (223 males, 205 females).	Participants interviewed regarding frequency of consumption of foods for 1 year prior to onset of symptoms. Fiber was part of normal diet (calculated by Southgate's tables or Lanza and Butrum).	Colon cancer risk decreased with intake of grain fiber for males and females, and with fiber from fruits and vegetables for males. Insoluble grain fiber was associated with reduced cancer risk more strongly than soluble fiber. Risk of rectal cancer was reduced in those consuming more fruit or vegetable fiber but not grain fiber.	Data analysis was not controlled for micronutrients or fat.

TABLE 2.—DIETARY FIBER AND COLORECTAL CANCER: CASE CONTROL STUDIES—Continued

Study	Type and Location	Subjects	Methods	Results	Comments
Hoff et al., 1986 (Ref. 15).	Case control,	155 men and women (78 with colonic polyps and 77 without polyps.	Subjects were participating in colon polyp endoscopic screening project. They recorded food intake for 5 consecutive weekdays. Bread was analyzed, gravimetrically, for total fiber. Fiber in other dietary components estimated by use of computerized Norwegian food composition data base.	Intakes of fiber was significantly less and total carbohydrate lower in patients with large polyps vs. those without polyps. Differences in intake of cruciferous vegetables, vitamin C, animal protein were not significant. Patients with large polyps consumed significantly more fat than patients without polyps. A lower intake of vitamin C or cruciferous vegetables correlated with the presence of multiple polyps.	Individuals were unaware of their polyp status when completing dietary information, a major strength of the study. Shows a protective effect of dietary fiber and total carbohydrates. Cruciferous vegetables and vitamin C intakes were protective against multiple polyp development.
Kune et al., 1987 (Ref. 21).	Case control, Melbourne, Australia.	392 colon cancer patients; 323 rectal cancer patients 727 community controls.	Patients were identified over a 1-year period. Usual diet, covering previous 20 years, was determined by interview with dietitian. Seasonal variations in diet were accounted for. Cancer patients were interviewed postoperatively in the hospital. Nutrients analyzed for included protein, fat, fiber, energy, β carotene and vitamin C.	Variables not contributing to, or contributing very little to, variation in colorectal cancer risk included fats; carbohydrates; fiber from pulses, nuts, seeds; fruit; cereals; energy; retinol in the diet; meats; and milk products (not milk drinks). Combination of high fiber, high vegetable diet was protective against colorectal cancer.	Difficult to interpret interaction effects. Type of fiber (soluble vs insoluble) was not analyzed.
Lee et al., 1989 (Ref. 23).	Case control, Singapore, China.	132 colon cancer patients; 71 rectal cancer patients—all hospital based 426 controls selected from other wards of the same hospital.	Dietary intake was calculated from food frequency questionnaire, providing information of usual dietary intake one year prior to interview. Fiber intake calculated from investigator's own determinations of fiber in local foods, as well as from food composition tables.	Colon cancer: significant protective effect from cruciferous vegetables. No significant effect of dietary fiber. High meat/low vegetable intake was a risk factor. Rectal cancer: significant protective effects noted for cruciferous vegetables, total vegetables, β-carotene, and total dietary fiber.	Number of cases (especially of rectal cancer) was small. Cruciferous vegetable intake and a high vegetable to meat intake ratio cited as most strongly protective factors. Fiber protective only for rectal cancer.
Slattery et al., 1989 (Ref. 41).	Case control, Utah	410 colon cancer cases. Combines patient data from 2 previous studies.	Dietary data obtained by food frequency questionnaire within 6 months of diagnosis. Data collected referenced 2–5 yrs before diagnosis of colon cancer. Crude dietary fiber calculated from prediagnosis food intake. Base diet was precancer diagnosis.	Highest quartile of crude fiber intake correlated with ↑ risk of death. No clear intake response effect.	Uses crude dietary fiber.

TABLE 2.—DIETARY FIBER AND COLORECTAL CANCER: CASE CONTROL STUDIES—Continued

Study	Type and Location	Subjects	Methods	Results	Comments
Slattery et al., 1988 (Ref. 40).	Case control, Utah	231 cases of colon cancer 391 controls: 185 males & 206 females. Cases and controls were all caucasians. Controls selected by random digit dialing.	Subjects were interviewed about diet 2 years prior to diagnosis. Dietary fiber intake calculated from some direct food analyses or from tables. Values computed for neutral detergent fiber, dietary fiber, and crude fiber based on food frequency questionnaire interview.	Significant dose-response risk reduction for crude fiber in males. Weak inconsistent effect for neutral detergent fiber. No effect of dietary fiber (analyzed by method of Bitner) or grain fiber. Data for females was similar, but 95% confidence intervals included 1.0. Significant intake-response risk reduction for fruit fiber in males. Lesser effect for vegetables, no effect for grain fiber. In females, vegetables showed a significant protective effect. Fruit fiber followed a dose response but 95% confidence intervals included 1.0. Data adjusted for calorie intake age and elevated body mass index (risk factors for colon cancer in this study) and Mormon church membership.	This study is one of the few published studies that examined the effect of several analytically defined fiber fractions on colon cancer risk. Crude fiber was the fraction most strongly associated with risk reduction. The authors note that the number of cases limits the ability to be more detailed about fiber types (sugar composition, etc.) or monitor differing effects on proximal vs. distal colon.
Tuyns et al., 1987 (Ref. 44).	Case control, Belgium...	818 cases of colon or rectal cancer; 2851 controls in 2 provinces of Belgium with differing dietary habits.	Patients asked about usual weekly intake for 1 week before onset of illness or at time of interview for controls. Total dietary fiber was calculated at 17.5–22.8 g/day (Southgate tables).	Significant ↓ risk of colorectal cancer with ↑ fiber consumption in both sexes and in both provinces. When adjusted for calorie intake, dose response was stronger. Also noted was a protective dose response for "polysaccharides" (starch) when adjusted for calorie intake.	Overall, showed a protective effect of total fiber.
West et al., 1989 (Ref. 48).	Case control, Utah	231 colon cancer cases: 112 males and 119 females. 391 controls: 185 males and 206 females from same community.	Food intake from subject's diets assessed by a food frequency questionnaire for the 2-3 yrs prior to interview. Fiber calculated from USDA data base and analyses of grocery foods. Data not controlled for micronutrient or fat intake.	This study reports a statistically significant ($p<0.10$) effect of crude fiber on reducing risk of colon cancer in males and females, after adjusting for age, body mass index, and energy intake. A modest intake response effect was seen for both sexes.	Apparent fiber effect may have been due to other factors in fruits and vegetables. 90% confidence intervals used in statistical analysis.
Wohlleb et al., 1990 (Ref. 50).	Case control, Arkansas.	Male VA patients: 43 with resected colorectal cancer 41 elective surgery patients.	Self administered questionnaire used to estimate approximate weekly intake of 55 food items (surveyed present diet), selected to estimate intakes of fat, fiber, vegetables, and meat. Total food consumption not recorded; did take weight and height measurement.	Study showed protective effect of wheat bran and cauliflower. Luncheon meats associated with increased risk.	Study does not examine fiber per se. Small sample size.

TABLE 3.—DIETARY FIBER AND COLORECTAL CANCER: COHORT STUDIES

Study	Type and location	Subjects	Methods	Results	Comments
Heilbrun et al., 1989 (Ref. 13).	Cohort study, records reviewed retrospectively. Hawaiian Japanese.	Subjects chosen from a group of 8,006 Hawaiian Japanese. 102 colon cancer cases; 60 rectal cancer cases.	Subjects followed for cancer occurrence for 17–20 yrs. Subjects consumed usual diet. Fiber calculated from a single 24 hr. recall taken upon entry into study in 1965–1968. Range of calculated dietary fiber intake was 1.3–43.2 g/day. Method of calculating dietary fiber not clear from text.	No effect of dietary fiber on relative risk of colon cancer in entire cohort. When group was divided in half (based on median fat intake) fiber conferred a significant protective effect only in the "low fat" half of the cohort. Vegetables/fruits also showed protective effect.	Authors consider results "preliminary" because limited #'s of cases precluded definitive analysis of fat effect. As in many other DF studies, fruits and vegetables also showed a protective effect. Only one 24 hour dietary recall (15 years before end of study) interview used to assess fiber intake. This may not accurately assess habitual diet.
Willet et al., 1990 (Ref. 49).	Prospective cohort.....	88,751 subjects (female nurses, 30–55 years old) available for follow up; 150 cases of adenocarcinoma of colon.	Study of the relationships between intakes of meat, fat, and fiber and colon cancer. Follow up since 1976. Dietary questionnaire used to estimate fiber from usual diets. Used crude dietary fiber or Southgate tables.	No evidence for protective effect of crude dietary fiber on colon cancer. High intake of crude fruit fiber, but not vegetable or cereal fiber, was protective. However, adjusted for red meat consumption, the effect disappeared.

21 CFR PART 101

[Docket No. 91N–0099]

RIN 0905–AB67

Food Labeling: Health Claims; Dietary Fiber and Cardiovascular Disease

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing that after review of the available evidence, it tentatively finds that a basis does not exist on which to authorize the use on foods, including dietary supplements, of health claims relating to the association between dietary fiber and cardiovascular disease. While an association appears to exist between consumption of fiber-rich foods and reduced risk of cardiovascular disease, FDA tentatively finds that it cannot attribute this effect to the fiber itself. Therefore, FDA specifically requests comments on this topic. FDA has reviewed the relationship between this dietary component and this disease under the provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments).

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the 1990 amendments.

ADDRESSES: Written comments to the Dockets Management Branch (HFA–305), Food and Drug Administration, rm 1–23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Joyce J. Saltsman, Center for Food Safety and Applied Nutrition (HFF–265), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–485–0316.

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101–535), which amended the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary) to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under section 403(r)(1)(B) of the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this Federal Register is a proposed rule to establish general requirements for health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs, or other nutritional substances (referred to generally as "substance" to a disease or health related condition on food labels and in labeling. In this companion document, FDA has tentatively determined that such claims would only be justified for substances in dietary supplements, as well as in conventional foods, if the agency determines, based on the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (section 3(b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)) that within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act (21 U.S.C. 343), and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including dietary fiber and cardiovascular disease, meet the requirements of the act.

In this document, the agency will consider whether a claim on food or

food products, including dietary supplements as well as conventional foods, on the relationship between dietary fiber and cardiovascular disease would be justified under the standard proposed in the companion document entitled "Food Labeling: General Requirements for Health Claims for Food: Proposed Rule."

B. Basis for Considering a Claim Relating Dietary Fiber and Cardiovascular Disease

1. Cardiovascular Disease

Cardiovascular disease is a major public health problem in the United States. Coronary heart disease (CHD) is the most common, most frequently reported, and most serious form of cardiovascular disease. CHD and stroke kill nearly as many Americans as all other diseases combined. Cardiovascular disease, primarily CHD is also among the leading causes of disability. These facts remain true despite the dramatic decline over the past 15 years in the death rate from cardiovascular disease: 35 percent for all cardiovascular disease, 40 percent for CHD, and more than 50 percent for stroke (Ref. 64). Changes in lifestyles, risk factor reduction, and medical intervention are major contributors to this decline (Ref. 64).

In order to be consistent with the magnitude of the public health problem and with the conclusions of the Federal government and other reports from recognized scientific bodies such as the National Academy of Sciences (NAS) and the Life Sciences Research Office (LSRO) (Refs. 40, 48, 63, 65, and 66), the focus of this document is CHD rather than the broader area of cardiovascular disease. CHD is not only considered to be the most common and most serious, but is also the earliest form of cardiovascular disease, frequently producing symptoms and health problems in middle-aged adults (Ref. 48). Despite a declining death rate from CHD since the mid 1960's, CHD still accounts for more deaths than any other disease or groups of diseases (Ref. 63). More than 1.25 million heart attacks occur each year (two-thirds occur in men), and more than 500,000 people die as a result (Ref. 63). In the United States, it is very common for significant pathogenesis of CHD to occur without easily detectable symptoms (Ref. 66). Thus, the total affected population is considerably larger than the statistics on death and illness would indicate. In addition to its impact on the nation's health, CHD costs the U.S. economy over $50 billion annually (Ref. 63).

2. Dietary Fiber

Dietary fibers are comprised of components of plant materials that are resistent to human digestive enzymes (Refs. 39 and 48). These components are predominantly nonstarch polysaccharides and lignin and may include, in addition, associated substances (Ref. 46). To date, the best documented and most accepted nutritional role for dietary fibers is for normal bowel function and health (Refs. 39, 49, and Canadian comments: FDA Docket No. 91N-0099). It is generally assumed that current fiber intakes in the United States of 10 to 15 grams (g) per day (6 to 7 g per 1,000 kilocalories (kcal) are less than optimal for meeting these needs (Refs. 36 and 39). Significant increases in this level of intake have been recommended frequently (Ref. 39).

Based on currently available analytical methods, dietary fiber is frequently measured as total dietary fiber and as the subcomponents of soluble and insoluble fibers (Ref. 39). Until recently, epidemiologic and other studies were not able to evaluate total dietary fiber intake because the majority of food composition tables contained no values for total dietary fiber content of foods. In addition, no standardized definitions of dietary fiber or dietary fiber components have been agreed upon.

Naturally occurring fibers in food are usually a mixture of the insoluble fibers such as cellulose and lignin; soluble fibers such as pectins, gums, and mucilages; and combinations of soluble and insoluble fibers such as hemicelluloses (Ref. 40). The proportions and types of fiber subcomponents vary among foods (e.g., oatmeal contains relatively large amounts of soluble fiber, and whole wheat bread contains relatively large amounts of insoluble fiber), and fiber content also varies within a food item or food group depending on the maturity of the plant, storage and ripening conditions, and food processing techniques used, if any.

In evaluating the biological effects and health consequences of dietary fiber intake, dietary fiber intake has been expressed as:

(a) Total dietary fiber or as the major fiber subcomponents (soluble and insoluble fibers);

(b) Fiber-containing foods (e.g., whole grains, legumes, fruits, vegetables);

(c) Fiber-rich food isolates (e.g., wheat bran, oat bran, corn bran, soy isolates); or

(d) Isolated and purified fibers (e.g., cellulose, pectins, lignin).

3. Relationship of Dietary Fiber and Cardiovascular Disease: Theoretical Basis

Many risk factors contribute to the development of cardiovascular disease, and specifically to CHD. There is general agreement that elevated blood cholesterol levels are one of the major "modifiable" risk factors in the development of CHD (Refs. 63 through 66). Federal government and other review (Refs. 48 and 63 through 66) have concluded that there was substantial epidemiologic and clinical evidence to indicate that high blood levels of total cholesterol and low density lipoprotein cholesterol (LDL-cholesterol) are reliable indicators of the development, severity, and rates of atherosclerosis (inadequate circulation of blood to the heart due to narrowing of the arteries) and constitute a major contributor to CHD (Refs. 48 and 63 through 66). Factors that decrease total blood cholesterol and LDL-cholesterol also tend to decrease the risk of CHD. Thus, it is generally accepted that total blood cholesterol and LDL-cholesterol levels can predict the risk of developing CHD, and that dietary factors affecting blood cholesterol levels are related to CHD (Refs. 48 and 63 through 66).

Populations with relatively low serum cholesterol levels tend to have dietary patterns that are low in fat, especially saturated fat and cholesterol, and that are relatively high in fiber-rich foods (e.g. fruits, vegetables, and whole grain cereals) (Refs. 48 and 63 through 66). Because of the relationship between serum cholesterol and CHD, all current dietary guidelines in the United States recommend dietary patterns that are likely to lower serum cholesterol levels: Reductions in dietary intakes of fat, saturated fat, and cholesterol and increases in intakes of vegetables, fruits, grain products, and cereal products (Refs. 48, 62, 63, and 66).

The association between dietary patterns rich in fibercontaining foods and lower levels of serum cholesterol is the theoretical basis for consideration of the appropriateness of a health claim for dietary fiber and reduced risk of developing CHD. Various beneficial health effects, including effects on lipid (fat) metabolism, have been suggested for fiber-containing foods and for dietary fiber, particularly the soluble dietary fiber component (Ref. 40). For these reasons, FDA limited its review of the relationship of dietary fiber and cardiovascular disease to dietary intake of soluble fiber effect on blood lipid levels and to risk of developing CHD. Based on conclusions from Federal

government reviews, total blood and LDL-cholesterol were accepted as valid indicators of risk of developing CHD. This focus is most consistent with current dietary guidelines for the U.S. population (Refs. 48 and 62 through 66).

(The relationship of dietary fiber to cancer is addressed in a companion document published elsewhere in this issue of the **Federal Register**. The relationship of cardiovascular disease to lipids and to omega–3 fatty acids are also addressed in companion documents published elsewhere in this **Federal Register**.)

C. Dietary Fiber: Regulatory and Legislative History

1. Early Claims for use of Dietary Fiber

Health attributes for fiber-containing foods have been claimed for over 100 years. Early interest focused on the benefits of wheat bran as a promoter of regular bowel function. Health claims for wheat bran on breakfast cereal packages became popular in the early 1900's, and the importance of adding "bulk" in the diet by the addition of dietary fiber appeared in advertisements that promoted the benefits of certain fibers as aids to digestion and to help relieve constipation. Such health claims on packages were mostly unregulated until after the act deemed products that carried such claims to be drugs and, therefore, subject to requirements of drug law. As a result, the use of health claims on food products virtually stopped until recently.

In 1941, the agency published regulations that included labeling requirements for "non-digestible carbohydrates" (6 FR 5921). At that time, foods having a high fiber content were valued because, when added to foods such as bread, lower caloric density was achieved. Based on the analytical procedures available at that time, the fibrous plant components of food had to be labeled as "crude fiber."

During the late 1970's, FDA sought to revise its regulations to include as fiber other fractions of carbohydrates, in addition to crude fiber, that are not digested by human enzymes. In doing so, the agency noted that the scientific evidence linking fiber to health outcomes was limited. In the **Federal Register** of December 21, 1979 (44 FR 75991), the agency stated that "* * * the relationship of dietary fiber to health remains controversial." Current § 105.66 (21 CFR 105.66) provides for the declaration of nonnutritive substances, but there is no regulation for declaration of fiber.

2. Food Additive Status

Substances that are added to food may be categorized based on their use as generally recognized as safe (GRAS) ingredients, food additives, or substances subject to a sanction or approval granted by the FDA or the United States Department of Agriculture (USDA) prior to September 6, 1958. The use of substances may be GRAS under the general principles set forth in § 170.30 (21 CFR 170.30), listed as GRAS in part 182 (21 CFR part 182), or affirmed as GRAS in Part 184 (21 CFR part 184). FDA's listings of food additives and affirmations that the use of a substance for direct addition to food is GRAS generally include the particular food categories in which (as defined in § 170.3(n)), and the specific technical effects for which (as defined in § 170.3(o)), the substance may be used.

"Fiber" is not considered to be either a food category or a technical effect according to the above definitions, and ingredients that are added to food are therefore not regulated as "fiber." However, FDA has regulated a number of isolated or purified fibers for specific technical effects in various food categories. For example, xanthin gum is listed as a food additive for use as a stabilizer, emulsifier, thickener, suspending agent, bodying agent, or foam enhancer (§ 172.645 ((21 CFR 172.695)); methyl cellulose is listed as a multipurpose GRAS substance ((21 CFR 182.1480)); and pectins are affirmed as GRAS for use as an emulsifier, stabilizer, or thickener (§ 184.1588). Guar gum is affirmed as GRAS for specific conditions of use that include those as an emulsifier, formulation aid, firming agent, and thickener (§ 184.1339). Guar gum has not been listed for use as a source of fiber, and under some circumstances, it has been shown to cause esophageal blockage and thus to be a health hazard. These and many other gums and fiber sources have no established history of food use, or safety as fiber supplements.

3. Dietary Fiber as Subjects of Health Claims

Prompted by the use (beginning in 1984) of information on high-bran cereal packages that high fiber diets may reduce the risk of cancer and by issuance of interim dietary fiber recommendations by the National Cancer Institute, FDA proposed in the **Federal Register** of August 4, 1987 (52 FR 28843), food labeling regulations to allow the use of health messages on labels and food labeling. The agency stated that food labeling could have an important influence on the public's food choices, and that truthful, nonmisleading health messages could increase consumer's understanding of the health benefits that can result from adhering to a sound and nutritious diet. This proposal set forth criteria for the evaluation of health claims.

In the **Federal Register** of February 13, 1990 (55 FR 5176), FDA published a reproposed rule that revoked the 1987 proposal and proposed to establish procedures permitting valid and reliable consumer information on food labels. The agency noted that the previous proposal was too ambiguous to be workable in preventing misleading claims. FDA thus proposed to tighten the requirements for health claims. The agency also proposed to evaluate the scientific evidence on six possible topics for health claims, including dietary fiber and cardiovascular disease.

On November 8, 1990, the President signed the 1990 amendments, which authorize FDA to issue regulations concerning claims on the label or labeling of foods that characterize the relationship between a substance and a disease or a health-related condition. As stated above, this law identified 10 substance-disease topics, including dietary fiber and cardiovascular disease.

D. Evidence Considered in Reaching the Decision

FDA has reviewed all relevant scientific evidence on dietary fiber and its effects on serum cholesterol. The scientific evidence reviewed by the agency included the summary, conclusions, and recommendations of all recent Federal government comprehensive reviews and dietary guidelines on this topic area: "The Surgeon General's Report on Nutrition and Health" (Ref. 63), the National Cholesterol Education Program's (NCEP) "Report of the Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults" (Ref. 65), the NCEP "Population Panel Report" (Ref. 66), the USDA and DHHS' "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 62), and the DHHS' "Healthy People 2000, National Health Promotion and Disease Prevention Objectives" (Ref. 64).

The agency also reviewed the evidence and conclusions in other nongovernmental documents: The LSRO report on "Physiological Effects and Health Consequences of Dietary Fiber" (Ref. 39), the National Research Council's (NRC) "Diet and Health, Implications for Reducing Chronic Disease Risks" (Ref. 48), the NRC's "Recommended Dietary Allowances"

(Ref. 49), and World Health Organization's (WHO) "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 71).

The agency updated these reports by independently reviewing all human studies and all reviews published since the Federal government and other authoritative documents completed their reviews of the literature. FDA considered animal studies to the extent that they helped explain possible mechanisms of action. FDA also contracted with LSRO to independently evaluate current evidence since their 1987 fiber report. A summary of the LSRO report, "Dietary Fiber and Cardiovascular Disease" (Ref. 40) is included in this review.

Finally, to ensure that its review of relevant evidence was complete, FDA requested, in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas identified in section 3(b)(1)(A) of the 1990 amendments. Dietary fiber and cardiovascular disease were among the 10 subjects for which the agency requested information.

E. Summary of Comments in Response to FDA Request for Scientific Data and Information

FDA received 1 comment in response to the February 13, 1990 reproposed final rule and 19 comments in response to the notice in the **Federal Register** of March 28, 1991 (56 FR 12932), concerning dietary fiber and CHD health claims.

One comment from a representative of industry was received in response to the reproposed final rule. Based on the findings of several authoritative documents and a review of additional references published since 1988, the comment suggested that the currently recommended low fat/low cholesterol diet could be made more effective in lowering blood cholesterol and risk of CHD by the inclusion of soluble fiber.

Of the 19 comments received in response to the March 28, 1991 notice requesting scientific data on dietary fiber and cardiovascular disease (under Docket No. 91N-0099), 13 were from industry; 4 from professional organizations; 1 from a consumer; 2 from health professionals; 2 from scientists; and 1 from the Government of Canada. The industry comments included primarily literature reviews and unpublished studies, which were included in FDA's science review of the scientific evidence. One food company did not support health claims on dietary fiber and risk of developing heart disease because of the multifactorial nature of the disease and the seriousness of the disease and suggested that medical intervention is required for proper diagnosis and monitoring of heart disease. All other industry and trade submissions supported the use of health claims.

Of the six comments from professional organizations, three submitted research reports generally supporting a health claim. Another called attention to the need for caution to avoid consumer misunderstanding. One comment pointed to the need to consider the overall diet context. Another took the position that the data on fiber and cardiovascular diseases are insufficient to support a claim.

The citizen comment included a literature search but no comment about the health claim issue.

The two comments from health professionals were divided. Although both provided data supporting their individual position, one was in favor of health claims and the other was not.

The Director General, Food Directorate, Health and Welfare, Canada, submitted information on the regulatory status of health claims in that country. The Canadian government is not in favor of health claims on fiber-containing foods because it is difficult to disassociate the metabolic effects of complex carbohydrates and the low fat content of these diets from those of dietary fiber. The comment said that this finding does not diminish the importance of diet as a factor in the maintenance of health but reinforces the importance of the whole diet rather than the contribution of individual components. Interactions between nutrients and between nutrients and nonnutrient components of the diet probably alter the likelihood of disease.

II. Review of Scientific Evidence

A. Federal Government Documents

Several Federal government documents (Refs. 62 through 64, 66, and 67) have concluded that the evidence for a role of dietary fiber in lowering the risk of cardiovascular disease, and more specifically CHD, is inconclusive.

The Surgeon General's Report (Ref. 63) comprehensively reviewed human and animal studies on CHD and blood cholesterol and noted that an extensive body of evidence supported by epidemiologic, metabolic, and animal studies has established the relationship among intake of saturated fat, high blood cholesterol, and increased rates of CHD (Ref. 63). The report also noted that based on ecological studies in several countries, dietary intakes that are high in starch (e.g., 60 to 70 percent of calories), such as those in Asian countries, are associated with low plasma cholesterol and a low rate of CHD. These diets tend to be high in fiber, lower in energy, and very low in fat, especially saturated fat and cholesterol. Several short-term clinical studies that were reviewed showed an association between water-soluble fiber fractions, such as oat bran, guar gum, and pectin, and cholesterol-lowering effects in hypercholesterolemic subjects (Refs. 7, 22, and 32). The report concluded that current evidence suggests the prudence of increasing consumption of whole grain foods and cereal products, vegetables (including dry beans and peas) and fruits (Ref. 63).

The recommendations of the NCEP (Refs. 65 and 66) are based on the goals of reducing blood cholesterol, and low density lipoprotein (LDL) cholesterol in particular, and providing a diet that is nutritious and palatable (Ref. 65). The LDL-cholesterol levels are directly correlated with risk for CHD (Ref. 65). The NCEP report concluded that changing American eating patterns will help lower blood cholesterol levels, thus reducing the risk of developing CHD. In this regard, the panel recommended lowering the intake of dietary saturated fatty acids, total fat, and cholesterol, and increasing the intake of fruits, vegetables, whole grain products, and legumes. These food items will help meet nutritional needs for minerals, vitamins, dietary fiber (including soluble fiber), and complex carbohydrates (Ref. 66).

The USDA/DHHS report "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 62) concluded that dietary fiber is important for proper bowel function and to reduce symptoms of chronic constipation, diverticular disease, and hemorrhoids. It stated that "populations like ours with diets low in dietary fiber and complex carbohydrates and high in fat, especially saturated fat, tend to have more heart disease * * *" (Ref. 62). The dietary guidelines noted the possibility that the benefit from a diet with more fiber may be from the food or component of the food providing the fiber rather than from the fiber alone. The USDA/DHHS dietary guidelines recommended choosing a diet with plenty of vegetables, fruits, and grain products.

In "Healthy People 2000," the Public Health Service and DHHS identified increased consumption of complex carbohydrates and fiber-containing foods by adults as a specific risk reduction objective (Ref. 64). Recommendations included increasing consumption of vegetables (including legumes) and fruits to five or more servings daily, and increasing

consumption of grain products to six or more daily servings. The report noted that dietary patterns with higher intakes of vegetables (including legumes), fruits, and grain products are associated with a variety of health benefits, including decreased risk for some types of cancer (Ref. 65). It was also noted that the association between diets high in complex carbohydrates (and fiber) and reduced CHD and diabetes mellitus is difficult to interpret because such diets tend to be lower in energy (calories) and fats, especially saturated fat and cholesterol. "Further research is needed to clarify whether the effect of dietary fiber on blood lipids is an independent effect, and if so, to quantify the relationship. (Ref. 64).

B. Other Review From Recognized Scientific Bodies

Several other comprehensive reviews from recognized scientific bodies on the role of nutrition and health have been published in recent years (Refs. 39, 40, 48, 49, and 71). The conclusions reached in these reports are similar to those reached in the Federal reports noted above.

In 1985, the Department of national Health and Welfare, Health Protection Branch, of the Canadian government convened an expert advisory committee to evaluate dietary fiber issues (Ref. 46). This committee noted that the relationship between the physico-chemical properties of dietary fibers and their physiological effects is difficult to evaluate partly due to the complexity of the interactions of mixed fibers in foods and in some instances, lack of uniformity in testing procedures. They recommended that manufacturers of food products to which nonnative and/or novel fibers have been added to increase dietary fiber content may be required to provide evidence substantiating the safety and efficacy of these products in terms of accepted physiological effects. Nonnative fibers were defined as fibers from traditional foods but not naturally occurring in the foods to which they have been added; novel fibers are those which have not traditionally been part of the human diet. They also recommended that manufactures of products which have been substantially enriched with native fibers should also be prepared to provide proof of efficacy on request. They noted that evidence is lacking that commercially produced products containing some of these materials will, when consumed, produce effects that the public has come to expect of fiber containing foods. They recommended more research to elucidate physiological forles of dietary fiber.

LSRO, in its 1987 report entitled "Physiological Effects and Health Consequences of Dietary Fiber" (Ref. 39), concluded that dietary fiber is an integral part of a healthy diet. However, LSRO stated that the available evidence is not sufficient to support specific, quantitative recommendations on the role of dietary fiber for the prevention of specific diseases in the general, healthy population. LSRO recommended, therefore, that a wide variety of fiber-rich foods be consumed, such as whole grain products, fruits, vegetables and legumes, because of the diversity of effects of various components of dietary fiber. The report stated that the foods eaten in the amounts suggested would provide about 20 to 35 g of dietary fiber per day (approximately 10 to 13 per 1,000 kcal) for the healthy, adult population (Ref. 39).

The 1989 NRC, NAS report, "Diet and Health—Implication for Reducing Chronic Disease Risk" (Ref. 48) reviewed epidemiologic and clinical studies and noted that increased consumption of fiber-rich foods was associated with a lower risk of developing CHD and other diseases. Diets providing 45 g of dietary fiber from fresh fruits, vegetables, and legumes (Refs. 20, 23, and 29), and with an isocaloric replacement of either sugar or bread with a mixture of vegetables providing 40 g per day of dietary fiber (Ref. 21), were associated with lower blood cholesterol levels. The NAS report concluded that although epidemiologic and clinical studies indicate that a diet consisting of complex carbohydrate and high-fiber foods may be associated with a lower risk of CHD, colon cancer, diverticulosis, hypertension, or gallstone formation, there is "no conclusive evidence that it is dietary fiber, rather than the other components of vegetables, fruits, and cereal products, that reduces the risk of those diseases" (Ref. 48). The NAS report recommended increased consumption of vegetables, fruits, breads, cereals, and legumes (Ref. 48).

The WHO report "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 71), stated that dietary factors are known to influence the development of a wide range of chronic diseases, including CHD. The report stated, the "affluent" type of diet that often accompanies economic development is energy (calorie)-dense. People consuming these diets characteristically have a high intake of fat (especially saturated fats) and free sugars and a relatively low intake of complex carbohydrates (from starchy, fiber-containing foods)." All of these factors influence serum cholesterol and their combined effects "may be important in modifying the rate of progression of atherosclerosis."

Based on direct experimental evidence concerning the association between dietary fiber, stool bulk, and intestinal transit time, WHO recommended a lower limit of intake of 16 grams per day of dietary fiber (nonstarch polysaccharides) and an upper limit of 24 g per day. This goal is consistent with an intake of about 27 to 40 g per day of total fiber, which includes other fiber components (Ref. 71).

The 1991 LSRO report "Dietary Fiber and Cardiovascular Disease" (Ref. 39) reviewed epidemiological studies since LSRO's 1987 report and found no new evidence to support reduced risk of CHD from an intake of dietary fiber and particularly soluble fiber. LSRO found that studies suggest that soluble fiber is hypocholesterolemic, while insoluble fiber is not. "Whether the observed effects result strictly from the fiber or from other components of the fiber-rich food or to a combination of these remains to be determined. (Ref. 39). The report also noted that it is also not known if a fiber present in a food is the same as when it has been extracted and purified.

C. Review of the Scientific Evidence: Evidence for an Association Between Intake of Soluble Dietary Fiber and Coronary Heart Disease

All of the government and other reviews by recognized scientific bodies cited above reviewed the evidence for an association between the intake of dietary fiber and CHD, one of the major cardiovascular diseases. It has been established that appropriate dietary intervention, resulting in lower serum total cholesterol, can reduce the incidence of CHD and hence the incidence of cardiovascular disease (Ref. 66; companion document on proposed rules for Health Claims: Lipids and Cardiovascular Disease). The review of studies that follows will also focus, as in the Federal government and other reviews by recognized scientific bodies, on evidence for the beneficial effects of dietary fiber, specifically soluble dietary fiber, on lowering blood total and LDL-cholesterol levels with the ultimate outcome of reduced risk of developing CHD.

The comprehensive government and other reviews by recognized scientific bodies concluded, based on evidence presented to date, that dietary patterns that included fiber-rich foods were associated with lower levels of blood

cholesterol and hence lower rates of CHD. Additionally, these reports suggested that if fiber has an effect on serum cholesterol levels, it is probably related to the soluble dietary fiber component, rather than to total, or insoluble, dietary fiber. However, these reports also noted the lack of evidence that would substantiate that it is the soluble fiber component of these foods, rather than some other concomitant change in nutrient intake or weight control, that is the responsible agent for these associations. For this reason, the nutrition guidelines that have been promulgated have emphasized changes in dietary patterns rather than specifically focusing on changes in soluble fiber intakes.

The agency, therefore, concluded that to provide adequate support for a role for dietary fiber, and in particular soluble dietary fiber, in reducing the risk of CHD, the updated evidence would need to specifically show that soluble dietary fiber at some specific level in the total diet has an effect.

1. Criteria for Selection of Human Studies

The agency evaluated all human data published after 1987, the time at which the NAS report (Ref. 48) completed it's review of the scientific evidence. The criteria that the agency used to select pertinent recent studies required that the studies:

(1) Present primary data and adequate descriptions of study design and methods;

(2) Be available in English;

(3) Include estimates, or enough information to estimate, soluble dietary fiber intakes;

(4) Include direct measurement of blood total cholesterol and other blood lipids related to CHD;

(5) For intervention studies, be conducted for a long enough duration to reasonably assure stabilization of blood lipids (greater than or equal to 3 weeks duration); and

(6) Be conducted in persons who generally represent the healthy U.S. population (adults with blood total cholesterol levels less than 300 miligrams (mg) per deciliter (dl).

2. Criteria for Evaluation of Human Studies

FDA evaluated the results of studies against general criteria for good experimental design, execution, and analysis. The criteria that the agency used in evaluating these studies included reliability and accuracy of the methods used in nutrient intake analysis, including measurements of total dietary soluble fiber and total dietary fiber; measurement of study endpoints (i.e., blood total cholesterol and other blood lipids related to CHD); and general study design characteristics, including randomization of subjects, appropriateness of controls, selection criteria for subjects, attrition rates (including reasons for attrition), potential for misclassification of individuals with regard to dietary intakes, presence of recall bias and interviewer bias, recognition and control of confounding factors (for example, intake of saturated fat and other nutrients, monitoring body weight, and control of weight loss), appropriateness of statistical tests and comparisons, and statistical power of the studies.

The availability of information on the total dietary fiber and total dietary soluble fiber content of baseline, treatment and control diets; the soluble fiber content of the test substance; and nutrient intakes were deemed highly desirable. In many cases, analytical or calculated values were not given for total fiber or for total soluble fiber components of the test diet, although in some cases, it was possible to roughly estimate soluble fiber values above baseline levels from available data on the amount and type of test material added to the diet.

Several research reports were based on studies of only a few weeks duration. To ensure that results were not reflective of transient changes, such as failure of blood cholesterol levels to stabilize to the dramatic changes in dietary patterns that occur with the introduction of large amounts of test substances, studies with treatment periods of less than 3 weeks were not considered in the agency's evaluation of scientific evidence.

The agency excluded studies that were published in abstract form because they lacked sufficient detail on study design and methodologies, and because they lacked necessary primary data. Studies using special population groups, such as insulin-dependent diabetics, individuals with very high serum cholesterol (mean greater than 300 mg per dL), children with hypercholesterolemia, and persons who had already experienced a myocardial infarction were also generally not weighed heavily because the relevance of health claims for the general healthy U.S. population is the key question. (Descriptions of all available studies are, however, included in Table 1).

3. Summary of Human Studies

Responses of blood cholesterol levels to dietary treatment are affected by many factors, including initial (baseline) blood cholesterol levels and dietary factors (i.e., the level of saturated fat and cholesterol in the diet) (Refs. 48, 65, and 66). Previous reviewers have generally concluded that in persons with relatively higher baseline levels of blood cholesterol, responses to treatment protocols tend to be of larger magnitude than is seen in persons with more normal blood cholesterol levels (Refs. 48, 65, and 66). For this reason, FDA separately evaluated studies on mildly to moderately hypercholesterolemic individuals (persons with elevated blood total cholesterol levels of 200 to 300 mg per dL) and normocholesterolemic individuals (persons with normal blood total cholesterol levels, less than 200 mg per dL). Since dietary intakes of saturated fat and cholesterol may also affect blood cholesterol levels, FDA also separated its review of studies on the basis of whether fiber effects are being evaluated as part of a "typical" American diet (approximately 37 percent of calories from fat, 13 percent of calories from saturated fat, and greater than 300 mg of cholesterol daily), or whether the test protocols are incorporated into a Step I or similar (e.g., American Heart Association) dietary regimen (less than 30 percent of calories from fat, less than 10 percent of calories from saturated fat, and less than 300 mg cholesterol daily). Detailed summaries of the reviewed studies are in Table 1.

a. *Hypercholesterolemics: "typical" or "usual" diets.* In two metabolic ward studies of 3 weeks duration (Refs. 3 and 4), soluble fiber intakes of 7 to 8 g per day were associated with reductions of 8 to 12 percent in blood total cholesterol level as compared to baseline levels. In both studies, groups experienced some weight loss (approximately 2 to 3 pounds) during the study period. In one study (Ref. 4), blood total cholesterol levels were measured several times throughout the study. The lowest values were observed at an intermediate time; that is, the initial drop in blood cholesterol levels was followed by a trend towards return to baseline levels at the end of the 3-week test period.

In a randomized, controlled, intervention study where subjects were free-living, Van Horn et al. (Ref. 69) assigned 80 men and women (25 to 76 years; serum cholesterol of 213 to 285 mg per dL) to either a control group (regular diet) or a test group which consumed their regular diet plus a cereal providing 2 g of soluble fiber daily. After 4 weeks of intervention, the test group, as compared to the control group, had significantly different dietary intakes for a number of nutrients, including higher intakes of soluble and total fiber, and

lower intakes of saturated fat and cholesterol. Blood total cholesterol and LDL-cholesterol levels in the test group decreased by 6 percent and 9 percent, respectively, with no change in the control group.

Kahn et al. (Ref. 25), in a randomized, controlled, intervention study added four muffins containing a total of 6 g of soluble fiber to the daily diets of 16 free-living men and women. After 3 weeks, there were no significant differences in total blood cholesterol levels between test and control groups.

Kesaniemi et al. (Ref. 27), in a randomized, self-controlled, cross-over, intervention study, monitored 34 free-living men (serum cholesterol 223 to 238 mg per dL) who consumed a low fiber diet (3 soluble fiber daily) or a high fiber diet (13 g soluble fiber) for 8 weeks. When consuming the high fiber diet, blood total and LDL-cholesterol levels decreased significantly (5 percent and 7 percent, respectively). The high fiber group consumed significantly higher levels of vegetables, cereal, fruits, and berries, compared to the low-fiber group.

Kestin et al. (Ref. 28), in a randomized, double-blind controlled, cross-over study, fed diets containing 6, 7, or 10 g of soluble fiber per day to 24 men (29 to 61 years; serum cholesterol 186 to 293 mg per dL) for 4 weeks. The sources of soluble fiber varied among test groups. Compared to baseline, subjects consuming 10 g of soluble fiber per day had a significant decline in blood total cholesterol (5 percent), with the decrease mainly in the LDL-cholesterol fraction. The other levels of soluble fiber did not cause significant lowering of serum cholesterol.

In a 12-week randomized, double-blind, cross-over intervention study with two 6-week test periods and a 3-week washout between treatments, Lo and Cole (Ref. 43) fed diets containing 13 or 24 g total dietary fiber per day to 12 men and 8 women (27 to 60; serum cholesterol of 210 to 279 mg per dL). The difference in total dietary fiber intakes between the two protocols was due to the addition of soy fiber to the test diet. (Soy is a relatively rich source of soluble dietary fiber). The effects on blood cholesterol differed depending on order of dietary treatment. If soy-enriched diets were fed first, blood total and LDL-cholesterol levels decreased by 8 percent and 7 percent, respectively, compared to baseline. A significant decline (5 percent) in the LDL-cholesterol levels of the placebo group is also observed. However, when soy-enriched diets were fed after the base diet, there was no effect on blood cholesterol levels. Thus, most changes in blood cholesterol levels occurred during the first 6 weeks of treatment, regardless of diet group.

The effect of beta-glucan, a particular type of soluble fiber, was evaluated in a randomized, cross-over, intervention study by McIntosh et al. (Ref. 44). Twenty-one men (30 to 59 years; serum cholesterol 209 to 270 mg per dL) received a diet containing either 8 or 1.5 g added beta-glucan daily for 4 weeks. Total soluble fiber intakes from the two diets were held constant at 13 g per day. Treatment order has an effect, with the group receiving the beta-glucan-enriched diet first showing no changes in serum total cholesterol, while those consuming this diet as the second dietary protocol showed a decline in blood cholesterol levels.

The effectiveness of high dietary fiber on the blood cholesterol levels of men who had already suffered heart attacks was studied by Burr et al. (Ref. 13). In a 2-year intervention study, over 2,000 men (mean age 56 years) were randomly assigned to several diet groups. One group was given advice to decrease fat intake to less than 30 percent of calories and to increase the ratio of polyunsaturated fat to saturated fat. Another group was advised to increase cereal fiber intake to 18 g per day. There were no significant differences in total mortality or in blood cholesterol levels between these groups.

Bulk laxatives (e.g., psyllium) or gums have been used in several study protocols as sources of supplemental soluble dietary fiber. Stewart et al. (Ref. 55), in an intervention study, compared blood cholesterol levels of 175 elderly (mean age 77 years) who had consumed a bulk laxative rich in soluble fiber for at least 1 month with those who had not been users of these products. The period of use of the bulk fiber supplement ranged from 1 month to 1 year. Those taking greater than 15 g of supplemental soluble fiber per day had a 4 percent lower total blood cholesterol level than those taking less than 8 g of supplemental soluble fiber per day. The use of supplemental fiber without specification as to amount versus no use of supplemental fiber was not associated with any differences in blood cholesterol levels.

In a controlled intervention study, McIvor et al. (Ref. 45) gradually increased the soluble fiber intakes of 8 obese men and women with noninsulin dependent diabetes (ages 45 to 50 years; mean serum cholesterol 222 mg per dL) by increasing consumption of granola bars enriched with a concentrated source of soluble fiber. Up to 22 g of supplemental soluble fiber were consumed per day in addition to that contained in subject's usual diets. After 6 months, serum total cholesterol levels did not differ significantly from baseline levels.

Superko et al. (Ref 56), in a randomized, single blinded, cross-over study, evaluated the relative effects of two different types of an isolated soluble fiber source on blood cholesterol levels of 50 men (39 to 63 years; serum cholesterol of 205 to 282 mg per dL). The fiber supplement added approximately 10 of soluble fiber daily to the regular diet. Although differences were observed in blood cholesterol levels after 4 weeks, at the end of 8 weeks there was no significant difference between the fiber supplement and the placebo groups.

Twenty-six men (30 to 65 years; serum cholesterol 188 to 314 mg per dL) consumed their regular diets and also consumed either a bulk laxative rich in soluble fiber or a placebo prior to each meal for 8 weeks in a randomized, parallel, double-blinded, placebo-controlled, intervention study (Ref. 8). The fiber supplement added approximately 8 to 9 g of soluble fiber to the regular dietary intake. From baseline, the group on the soluble fiber-enriched protocol had a significant decrease in blood total cholesterol (15 percent) and LDL-cholesterol (20 percent).

In summary, several studies were reviewed in which conventional foods high in soluble fiber (e.g., beans or oatmeal) or enriched with soluble fibers (baked goods with added wheat, barley, or oat brans) (Refs. 3, 4, 13, 25, 27, 28, 43, 44, and 69) were used to increase the soluble fiber intakes of subjects. The study durations ranged from 3 weeks to 8 weeks, except for one 2-year study which was of limited value since it did not provide information on soluble fiber intakes (Ref. 13). Although information on total intakes of soluble fiber was not always provided, there was enough available information to make crude estimates of intake. These estimates suggested that, under study conditions used, intakes of soluble fiber above 6 to 12 g per day were generally associated with reductions in blood total and, when measured, LDL-cholesterol levels. The potential for differences in effectiveness among different sources of dietary fiber when total intakes are similar was suggested by two studies (Refs. 27 and 28) and by the equivocal results from several isolated sources of soluble fiber (Refs. 8, 45, 55, and 56).

Several studies used isolated sources of soluble fiber (psyllium and guar gum) either under standard pharmacological conditions in bulk form with meals (Refs. 8 and 55) or incorporated into

baked goods (Ref. 45) to increase soluble fiber intakes. Duration of studies ranged from 8 weeks to 1 year. Generally, much higher intakes of soluble fiber were achieved (15 or more per day) with use of supplements as compared to foods (approximately 2 to 12 g daily). One study of 6 months duration (Ref. 45) showed no effect on blood cholesterol levels, although the small sample size (n=8) may lack adequate statistical power. Another study showed rather small changes in blood cholesterol levels (4 percent) with 175 subjects consuming high (15 g or more) versus low (less than 8 g) of supplemental soluble fiber for 1 month to 1 year. Use versus nonuse of supplements showed no relationship to blood cholesterol levels. A third study showed 15 and 20 percent reductions in blood total and LDL-cholesterol after consuming 8 to 9 g of supplemental fiber for 8 weeks (Ref. 8). Finally, results of a fourth study suggested that effects may be transient (Ref. 56), with effects observed at 4 weeks disappearing by the end of 8 weeks.

b. *Hypercholesterolemics: Step 1 diets.* In several studies, the relative effectiveness of Step 1 diets (less than 30 percent calories as fats, less than 10 percent calories as satuated fat, and less than 300 mg cholesterol daily) with and without added soluble fiber were evaluated. In a metabolic ward study, Anderson et al. (Ref. 5) fed Step 1 diets containing 9 g soluble fiber per day to 10 men (40 to 70 years; serum cholesterol 200 to 320 mg per dL) for 3 weeks. The baseline diet contained 3 g soluble fiber daily. There were no significant decreases in total blood cholesterol following consumption of the high fiber diet, but LDL-cholesterol decreased significantly from baseline levels (8 percent decline).

Little et al. (Ref. 42), in a controlled intervention study, examined the effect of 4 types of dietary intervention on blood total cholesterol levels of 184 free-living men (58 to 61 years; serum cholesterol 240 to 267 mg per dL). After 8 weeks, declines in serum cholesterol were the same (approximately 5 percent) for both a low fat diet alone and for a low fat, high fiber diet (total dietary fiber of 40 to 45 g per day; no data on soluble fiber). The authors suggested that low fat rather than increased levels of dietary fiber were responsible for changes in serum cholesterol.

Demark-Wahnefried et al. (Ref. 16), in a randomized intervention study, monitored blood cholesterol levels in 81 men and women (20 to 65 years, mean baseline serum cholesterol of 271 mg per dL) consuming one of four dietary protocols for 12 weeks: Step 1 diet alone, Step 1 diet plus added soluble fiber from 50 g of oat bran, regular diet plus 50 g of oat bran, and regular diet plus 42 g of processed oat bran. Declines in serum cholesterol occurred in all groups. Blood cholesterol levels of groups consuming diets containing the higher soluble fiber (approximately 4 g added soluble fiber daily) did not differ from groups on a dietary regimen modified only in fat and cholesterol content.

Levin et al. (Ref. 37), in a randomized, double-blind, intervention study, followed 58 men and women (21 to 70 years; baseline serum cholesterol of 235 to 245 mg per dL) who consumed a Step 1 diet for 8 weeks followed by 16 weeks of treatment with a placebo or concentrated soluble fiber source. The total soluble fiber intake of the test diet was estimated at 15 g per day compared to intakes of 6 to 8 g daily on the Step 1 diet alone. The group consuming the high soluble fiber diet showed a significant decrease in total and LDL-cholesterol (6 and 9 percent, respectively) from baseline.

Several studies examined the effect of type of fiber on blood cholesterol levels. Keenan et al. (Ref. 26), in a randomized, controlled, double-blind, intervention study with cross-over, used a 6-week pretreatment period to adapt subjects to a Step 1 diet. Then, holding total soluble fiber intakes constant at approximately 6 to 7 g per day, the relative effectiveness of wheat versus oat cereals as the fiber-enriching source were compared. Effects on blood cholesterol levels varied, depending on the order of feeding of the diets supplemented with oat bran or wheat cereal. Interpretation of results was further complicated by the fact that the control group showed an initial decline in blood cholesterol levels followed by a return to baseline at the end of the study.

Bell et al. (Ref. 12), in a randomized, double-blind controlled, intervention study, compared the effects of three diets containing corn flakes (control), pectin-enriched, or psyllium-enriched cereals. Fifty-eight subjects (24 to 69 years; serum cholesterol 227 to 229 mg per dL) consumed Step 1 diet for 6 weeks followed by 6 weeks on the cereal plus Step 1 diets. Total soluble fiber intake for the three diets was relatively constant at 6 to 8 g per day. Blood total and HDL-cholesterol was decreased significantly (6 percent) on the psyllium-enriched but not the pectin-enriched diet.

Several studies evaluated the effectiveness of beta-glucan, a particular type of soluble fiber found in oat products. In a randomized, controlled, intervention study, 351 men and women (20 to 60 years, serum cholesterol 200 to 300 mg per dL) were assigned to one of three dietary regimens: regular diet, Step I diet, or Step I diet plus the addition of about 10 g total dietary fiber (7 to 8 g soluble fiber as beta-glucans) (Ref. 10). There was variable weight loss among treatment groups. No data were provided on total soluble fiber content of the diets. After 8 weeks, reductions in blood total and LDL-cholesterol (decreases of 8 and 10 percent, respectively) were greater with the Step I diet than with no dietary change. Somewhat higher reductions (decreases of 12 to 15 percent) were observed when beta-glucans were added to the Step I diet.

In a randomized, single-blind, controlled intervention study, 146 men and women (30 to 65 years; serum cholesterol 230 to 319 mg per dL) consumed Step 1 diets with either zero or 5 to 7 g of soluble fiber added by incorporation of various types of cereal products (Ref. 15). After 6 weeks, groups consuming diets containing 4 to 6 g of beta-glucan had significant declines in blood total cholesterol (7 to 10 percent) and LDL-cholesterol (10 to 16 percent) as compared to baseline. Blood total cholesterol levels of groups consuming diets containing 1 to 2.4 g daily of beta-glucan did not differ significantly from baseline.

In summary, in the 4 studies with hyperlipidemics consuming diets low in fat, saturated fat, and cholesterol, the addition of soluble fiber to the diets produced equivocal results on blood cholesterol levels, ranging from no effect (Refs. 16 and 42) to 6 to 9 percent declines in blood cholesterol levels when 15 g of soluble fiber per day were consumed for 16 weeks (Refs. 5 and 37). Source of soluble fiber was evaluated in four studies (Refs. 10, 15, 12, and 26). Results were equivocal in one study and suggestive of a source or specific type of soluble fiber component effect in the other studies.

c. *Normocholesterolemics: "typical" or "usual" diets.* Van Horn et al. (Ref. 65), in an epidemiological cross-sectional survey, evaluated baseline dietary assessment and blood cholesterol data from the Coronary Artery Risk Development in Young Adults (CARDIA) study. Dietary intakes were assessed by diet history. Of the over 5,000 men and women (18 to 30 years; normal blood cholesterol levels), there was an inverse and statistically significant correlation between total dietary fiber intake and blood total

cholesterol and LDL-cholesterol levels. Many other nutrient intakes were also correlated with blood cholesterol levels. No data were given on soluble fiber intakes.

Seven men with normal blood cholesterol levels (mean 187 mg per dL) consumed their regular diets for 3 weeks followed by the addition of a supplemental source of soluble fiber for an additional 3 weeks (Ref. 1). The added soluble fiber intake was estimated at 16 to 19 grams per day. Blood cholesterol levels decreased during the pretreatment diet phase. After 3 weeks of supplemental soluble fiber intake, total blood cholesterol levels decreased 16 percent from the level at the end of the pretreatment phase.

Gold and Davidson (Ref. 19), in a double-blind, intervention study, provided 2 muffins containing test fibers (oat bran, wheat bran, or wheat/oat bran combination) to 72 male and female medical students (25 to 37 years; mean blood cholesterol 178 mg per dL) for 4 weeks. Subjects were assigned to one of three treatment groups, depending on soluble fiber intake from the muffins. Group mean supplemental soluble fiber intakes were 2.5, 0.9, and 0.33 g per day. Supplemental total dietary fiber was held constant at about 5 g per day. No data were given on baseline dietary fiber intakes. After 4 weeks, the group consuming 2.5 grams per day of supplemental soluble fiber had significantly lower blood total (5 percent) and LDL-cholesterol levels (9 percent) as compared to baseline levels.

In a controlled, cross-over, intervention study, Taneja et al. (Ref. 58) provided isaqbol husks as supplemental soluble fiber (20 to 22 grams per day) to 11 Indian girls, 16 to 18 years (mean serum cholesterol 182 mg per dL) for 3 weeks. The higher fiber intake was associated with a significantly lower blood total cholesterol level (7 percent) compared to the low fiber diet.

Thirty-four men and women college students (mean age 27 years; normal cholesterol) consumed formula diets standardized to reflect the fat and other macronutrient components of U.S. diets (Ref. 35). Various fiber sources and levels of soluble fiber were added by consuming breads and cereals. Dietary protocols in which soluble fiber intakes were 5 or more per day were associated with reduced levels of blood cholesterol; whereas soluble fiber intakes of 3 g or less per day did not show significant changes in blood cholesterol levels.

Swain et al. (Ref. 57), in a randomized, double-blind, cross-over, intervention trial, fed diets containing 4 or 15 g of soluble fiber per day for 6 weeks added as supplementary oat and wheat bran to subject's regular diets. Both the high and low fiber diets were associated with statistically significant decreases in blood total cholesterol levels as compared to baseline.

In a randomized, single-blind, intervention study to evaluate the effect of beta-glucan, a type of soluble fiber, on blood cholesterol levels, Newman et al. (Ref. 50), provided cereal and baked goods to 14 free-living men (35 years or older; serum cholesterol 141 to 247 mg per dL). Treatment diets were consumed for 4 weeks following 4 weeks of pretreatment with the normal diet. Pretreatment diets contained approximately 5 to 7 g of total dietary fiber. The total dietary fiber content of treatment diets was held constant at approximately 45 g of total dietary fiber; these diets, however, differed considerably in beta-glucan content. The high beta-glucan group also consumed less total fat than the control group. At the end of the 4-week treatment period, the blood cholesterol levels of the high beta-glucan group did not differ significantly from baseline. The blood total and LDL-cholesterol levels of the low beta-glucan group, despite high total dietary fiber intakes, were significantly higher than baseline levels.

In summary, for studies in persons with blood cholesterol levels in the normal to borderline or mild risk levels and consuming their regular diets, and within the context of the study conditions, results tended to show declines in blood cholesterol levels with intakes of soluble dietary fiber (Refs., 1, 19, 35, 57, and 58). One study controlled nutrient intakes by use of formula diets and results generally suggested a dose response to soluble fiber intakes (Ref. 35). Generalization to regular dietary patterns needs to be done cautiously. A study on beta-glucans, however, did not show an effect of this fiber in persons with normal blood cholesterol levels (Ref. 50).

d. *Normocholesterolemics: Step 1 diets.* Van Horn et al. (Ref. 68), in a randomized, intervention study controlled with crossover, stabilized 236 free-living men and women (serum cholesterol 163 to 247 mg per dL) on a Phase II American Heart Association diet (low fat, low saturated fat, low cholesterol). Test diets contained 4.2 g of added soluble fiber. After 8 weeks on the test diet, there were no significant differences in total serum cholesterol levels between groups, although blood cholesterol levels were significantly lower in the test group as compared to the control group at the interim 4-week time.

In a randomized, double-blind, placebo-controlled, parallel intervention trial, 75 men and women (mean blood cholesterol approximately 200 mg per dL) consumed a placebo test fiber for 8 weeks while also consuming a Step 1 diet (Ref. 11). The Step 1 diet provided approximately 6 g of soluble fiber per day; the test fiber supplement provided an additional 8 to 9 g of soluble fiber daily. After 20 weeks on the test diet, blood total and LDL-cholesterol levels were significantly reduced from baseline (4 percent and 8 percent, respectively). A subgroup of 30 subjects continued the intervention for 8 more weeks. Total and LDL-cholesterol levels tended to increase towards baseline in the supplemented group and to increase above baseline in the placebo group. The authors reported excellent compliance of the test substance throughout the study period.

In summary, only two studies were available in which the effect of soluble fiber on blood cholesterol levels was evaluated in persons with normal to mildly elevated levels and consuming diets low in total fat, saturated fat, and cholesterol. Results were equivocal but in both cases seemed to be transient since interim values were lower than final values. This occurred, despite the report of excellent compliance in consuming the test material in one study (Ref. 11).

4. Biological Mechanisms

Several mechanisms have been proposed to explain the claimed hypocholesterolemic effect of soluble fiber. These mechanisms have been reviewed in detail elsewhere (Refs. 17, 34, and 39) and will be briefly summarized here.

a. *Gastrointestinal events.* Dietary fibers affect different aspects of gastrointestinal function, resulting in interference in nutrient absorption and diffusion, altered hormonal responses, and production of short chain fatty acids. "These events could act individually or collectively to decrease serum cholesterol" (Ref. 2). However, effects on gastrointestinal functioning have not been studied adequately in the human body.

Studies outside of the body show that viscous fibers can influence the accessibility of absorbable nutrients to the mucosal surface. There are a variety of demonstrated and potential influences of high dietary fiber intake on both intraluminal and mucosal intestinal physiology that may affect the rate and extent of absorption of nutrients, including dietary lipids and cholesterol.

Dietary fiber may influence nutrient and cholesterol availability in its interaction with digestive enzymes, possibly leading to decreased efficiency of digestion and limited diffusion of absorbable products in the intestinal lumen. In rats, soluble fibers delay gastric emptying and interfere with nutrient exposure to digestive enzymes and absorptive surfaces of the small intestine. Viscous fibers, such as guar gum, show marked influence on lipid digestion in dogs. These fibers decrease the grinding and digestive action of the stomach, allowing poorly digested food to pass into the midintestine, leading to delayed lipid digestion.

Interaction between dietary fiber and the intestinal surface has not been studied adequately in humans. Vahouny and Cassidy (Ref. 75) noted that the effects of various fibers, especially viscous fiber preparations, on the activities of mucosal-associated digestive enzymes have not been consistent.

b. *Binding or sequestering bile acids.* Of all the theories proposed to explain the effects of dietary fiber on serum cholesterol that have been seen in some studies, the theory that fiber binds or sequesters bile acids has received the greatest attention and most extensive evaluation (Ref. 17). Dietary fats, or lipids, are first emulsified in the stomach and then are transferred to the upper part of the small intestine where they are hydrolyzed by pancreatic lipase. The hydrolysis products eventually dissolve in bile acids to form micelles. The micelles are broken at the intestinal wall, and the lipid hydrolysis products are absorbed into the body (Ref. 74). Specific dietary fibers are thought to bind or sequester circulating bile acids, thus interfering with micelle formation required for dietary cholesterol absorption, and thus altering or modifying lipid digestion and absorption. Increased excretion of bile acids in feces results in the conversion of liver cholesterol to bile acids, which eventually leads to decreased serum cholesterol and LDL-cholesterol levels.

In an effort to confirm this hypothesis, Story (Ref. 73) observed that the effects of dietary fiber on bile acid excretion are inconsistent and are not large enough to account for observed changes in serum cholesterol. "However, in some cases (e.g., oat bran in hypercholesterolemic humans), a substantial change in bile acid excretion has consistently accompanied the hypocholesterolemic effects. Clearly, this is not the sole mechanism involved for all sources of dietary fiber and our initial hypothesis concerning adsorption-excretion is not valid for all situations" (Ref. 73).

c. *Effect of fiber fermentation products.* Dietary fibers are partially fermented by bacteria in the human colon. Some of the fermentation products formed include short chain fatty acids, such as acetate, propionate, and butyrate. Short chain fatty acids are almost completely absorbed from the colon. Propionate is extracted by the liver and has been shown to lower plasma cholesterol in rats. In vitro studies in rat liver cells have shown that propionate decreases cholesterol synthesis, but only if acetate is used as a cholesterol precursor (Ref. 72). Venter et al. (Ref. 70) showed that dietary propionate fed to baboons raised total cholesterol, although metabolic effects of dietary propionate may not be the same as propionate derived from microbial fermentation of dietary fiber in the colon.

d. *Summary.* There are several mechanisms proposed (interference with gastrointestinal functions, binding of bile acids, and fiber fermentation) to explain the effects of soluble fiber on serum cholesterol found in some short-term studies. Not only is the mechanism unknown, but it has not been determined if it is the soluble fiber itself, the presence of beta-glucan (the major component of soluble fiber), or some other component in the diet that accounts for the observed effects.

5. Conclusions

Earlier reviews by the Federal government and other recognized scientific bodies generally concluded that diets rich in water-soluble fiber fractions were associated with cholesterol-lowering effects in humans (Refs. 48, 65, and 66). They further noted that high fiber diets are often associated with low fat diets and it is difficult to differentiate the effects of the two nutrients, although the net effect is beneficial and soluble fiber in relatively large amounts may serve as a useful adjunct to low saturated fat and low fat diets. The recent update by LSRO (Ref. 40) noted that recent data reflect results from earlier studies in that results suggest soluble fiber but not insoluble fiber may have cholesterol-lowering properties. Some types of soluble fiber, e.g., betaglucan, may be more effective than other types, although the data are extremely limited at this time. Animal studies are generally supportive. This report also notes that it is not clear whether the observed effects result strictly from the fiber or from other components associated with consumption of fiber-rich foods. The report also noted that there are no data to indicate that a fiber present in a food is the same as when it has been extracted and purified.

FDA reviewed over 30 human studies published in the last several years. Under the study conditions, many studies observed a decline in blood cholesterol levels with increasing intakes of soluble fiber. Most studies, however, were of very short duration and, therefore, cannot confirm long-term benefits from high soluble fiber diets. Indeed, questions of long-term effects were raised by the observation of an initial decline in blood cholesterol levels followed by a return upwards towards baseline in some of the longer studies, even when authors reported excellent compliance for consumption of test substances.

There was some evidence suggesting that different types of soluble fiber have different effects. Additionally there was some evidence of a dose response, although the evidence for this is very limited. There were, however, major design flaws in many of the studies which make it difficult to reach firm conclusions. The objectives of many study protocols seemed to be to evaluate the effectiveness of relatively large amounts of a single type of food or fiber source rich in soluble fiber (e.g., oatmeal, baked beans, oat bran) rather than to look at total soluble dietary fiber intakes or to specifically identify the chemical and physical characteristics of soluble fiber that are most effective in lowering blood cholesterol levels. By adding large amounts of foods to diets (e.g., addition of 1 to 2 cups of baked beans daily), these dietary changes were often accompanied by lower calorie intakes and weight loss. Since weight loss alone can lower blood cholesterol levels, this becomes a serious confounder for interpreting study results. Frequently, also, nutrient intakes, particularly those nutrients related to serum cholesterol levels (saturated fat, total fat, cholesterol) varied among treatment and control groups, again confounding interpretation of results. Information on total soluble fiber intakes is not always provided. Results from studies with crossover designs were often particularly confusing since treatment order effects were often observed.

The LSRO update report (Ref. 40) noted that the recent studies represented, to large degree, a repeat of earlier studies. FDA reached a similar conclusion. Based on the totality of the evidence, FDA has determined that the conclusions of the reports reached by the earlier Federal government and other reviews by recognized scientific

bodies provide an insufficient basis to support a health claim relating soluble fiber intake to reductions in blood cholesterol levels and, ultimately, to reduced risk of developing CHD. It is still not clear whether observed reductions in blood cholesterol levels on short-term studies are due to changes in other nutrients intakes and/or to concomitant weight loss. The potential for adaptation and loss of effectiveness with time remains an unanswered question. And, most importantly, the data suggest that some but not all components of dietary soluble fiber may be most effective. Evidence to date is too limited to be able to clearly identify the characteristics of effective soluble fibers.

III. Tentative Decision not to Propose a Health Claim Relating Dietary Fiber to Decreased Risk of Cardiovascular Disease

FDA limited its review of the scientific evidence relating to ingestion of dietary fiber and cardiovascular disease to the topic of soluble dietary fiber and risk of developing CHD. These limitations were deemed appropriate because the previous Federal government and other reviews by recognized scientific bodies had focused on these areas and the majority of research efforts to date have focused on these areas.

FDA has tentatively concluded, based on the totality of the evidence, that there is not a sufficient basis to authorize a health claim for dietary soluble fiber and reduction in risk of developing CHD. Numerous human studies have examined the possible role of dietary fiber intake in CHD. Many correlational studies show a relationship between diets high in plant foods (fruits, vegetables, and grains) and reduced rates of cardiovascular disease. There are a number of dietary intervention studies which are generally conducted for short-time periods, and often with fairly large changes in dietary patterns. Most of these studies show short-term benefits in serum cholesterol lowering with diets high in soluble dietary fiber. However, these studies are often also characterized by other concomitant changes which could also affect blood cholesterol levels, including weight loss and changes in other nutrients intakes which affect blood cholesterol levels. Studies of longer duration (6 weeks to 6 months) tend to be limited in number and results are more equivocal. The relationship of type of soluble fiber as currently measured by commonly used methods such as those of the Association of Official Analytical Chemists is not clear.

It is clear that diets high in soluble fiber-rich foods, including whole grains, fruits, and vegetables, are associated with reduced risk of developing CHD. These diets differ, however, in the levels of many nutrients and in types of dietary soluble fiber making it difficult to ascribe observed nutrient and disease relationships to a single nutrient. Overall, the available data are not sufficient to demonstrate that it is the total soluble dietary fiber, or a specific measurable and quantifiable subcomponent, that is related to lower blood cholesterol levels.

A major limitation in designing and evaluating research studies has been the need for better-defined measures of dietary fiber and standardized descriptions for source, type, and amount of dietary soluble fiber (Ref. 39). Dietary fibers, including soluble fibers, are a heterogeneous family of compounds that vary considerably in chemical composition, physical characteristics, and biological effects (Ref. 39). Processing of foods and fiber sources may also alter the inherent characteristics of the soluble fiber. The commonly used analytical methodologies often do not detect many of the characteristics that vary among fibers and that may be related to biological function (e.g., particle size, chemical composition, or water-holding capacity) (Ref. 39). Analytical methods also do not differentiate between source of fiber. This lack of ability to detect many of the differences that exist among fibers and the general lack of clear evidence as to the mechanisms of action of fibers have raised questions as to the ability of commonly used analytical measures of dietary fiber to adequately predict biological actions of specific fibers (Refs. 12 and 24).

Another problem in evaluating the relationship of dietary fiber intakes to the risk of chronic disease such as CHD is the lack of reference food composition data on the fiber content of foods. Consequently, most human studies have described dietary intakes in terms of amounts of oatmeal, or oat, or wheat brans. In many studies, total soluble dietary fiber intake, or even the soluble fiber content of the test material, was not described.

In summary, the currently available scientific evidence is not sufficiently conclusive or specific for soluble fiber to justify use of a health claim relating intake of dietary soluble fiber to reduced risk of CHD. Federal government (Refs. 63 and 66) and other reviews by recognized scientific bodies (Refs. 39, 40, and 48) are consistent in agreeing that it is difficult to separate the effects of fiber from those of other components present in high fiber foods or in dietary patterns high in plant food. As noted above, the evidence that has become available since publication of these reports is consistent with these conclusions and is, therefore, not sufficient to alter the earlier conclusions. Thus, FDA has tentatively concluded, based on the totality of the scientific evidence, that there is not significant scientific agreement among experts qualified by training and experience to evaluate such a relationship, as to the independent and specific role of dietary soluble fiber in reducing the risk of CHD.

FDA recognizes that CHD is a leading cause of morbidity and mortality in the United States and that changes in dietary patterns can play a significant role in reducing risk of CHD. Virtually all recent dietary guidelines for Americans have encouraged the increased consumption of fiber-rich foods, including whole grain cereals, fruits, and vegetables. FDA has supported and continues to support these recommendations and to encourage dietary guidance consistent with the recommendations. This raises a dilemma, however, for which FDA is requesting comment. To encourage and help consumers to meet dietary guidance recommendations, it would be useful to have appropriate dietary information at point of purchase. The use of health claims on foods (including dietary supplements) to inform consumers of these recommendations, however, is problematic since it is not clear what qualifying and other criteria are necessary to adequately define eligible foods for such a health claim. Congress, in the 1990 amendments, specified that FDA evaluate nutrient and disease relationships. Dietary fiber was specified as one nutrient for evaluation. Yet, FDA has tentatively concluded that the available evidence that is supportive of changes in food patterns cannot be extrapolated to a specific fiber effect at this time.

Given the public health significance of CHD and given the general dietary guidance to increase consumption of fruits and vegetables and whole grain products which are rich sources of dietary fiber, including soluble fiber, and other nutrients, FDA is requesting comments on how best to inform consumers of these issues.

Specifically, should the agency permit a claim on the label or in labeling such as "Diets high in fruit, vegetables, and whole grains are associated with a reduced risk of cancer of the lower bowel and cardiovascular disease"; or

alternatively "Research has shown that populations who consume diets that contain several servings each of fruit, vegetables, and whole grains have a decreased risk of certain forms of cancer and cardiovascular disease; or "Choose diets with plenty of fruit, vegetables, and whole grains to help lower your risk of cardiovascular disease and certain forms of cancer." If such statements should be permitted, what criteria should be used to identify foods that are eligible for such statements? For example, should such statements be limited to fresh fruit, vegetables, and milled whole grains, or should processed foods derived from these produces also be included? What measure should the agency adopt to assure that consumers are not mislead as to the benefit of consuming a specific product? FDA is requesting comments on whether it has the authority and should allow health claims on foods as well as nutrients.

Based on the studies reviewed in this document, serum cholesterol responses were affected by a number of factors: Initial serum cholesterol level, base diet, self-initiated changes to base diet (particularly to changes in intake of saturated fat and polyunsaturated fat) during the test period, body weight, exercise, medications, general health, and other lifestyle variables. These confounding factors, which were generally not well controlled within many of the individual studies and which make cross-study comparisons difficult, made it impossible to draw conclusions about the relationship of soluble fiber to serum cholesterol levels.

1. Safety of Fiber Supplements

Concerns have been raised about the potential for risk from isolated or purified forms of fiber (Ref. 39). Side effects and possible adverse health effects of high intakes of dietary fiber have also been hypothesized by NAS (Ref. 48). Excessive consumption of fiber supplements may result in more intestinal problems or poor absorption of trace minerals than would be expected from a high-fiber diet (Ref. 40). Fiber sources, such as psyllium seed, guar gum, pectin and other gums, are not listed as GRAS substances for use as a fiber supplement.

The agency is concerned about changing consumption patterns associated with the development and introduction into the marketplace of new sources of dietary fiber, along with increased use of fiber sources as food ingredients or as supplements of fiber. FDA intends to update its GRAS regulations for sources of fiber in the near future. To deal with this issue, the agency intends to initiate a review of the existing types of isolated dietary fibers and their use as a broad class of foods to identify and assess scientific information on the safety of this use. This review will include consideration of the biological effects of different fibers, the extent to which such effects are significantly different for subclasses of dietary fiber, and whether biological effects are significantly altered by chemical or physical changes and by processing. FDA may use the results of this or other reviews to develop a new strategy for assessing food safety.

2. Significant Scientific Agreement

The Federal government and other authoritative reports reviewed consistently concluded that while dietary patterns high in fiber-rich foods were associated with lower levels of serum cholesterol and decreased risk of CHD, the effect of soluble dietary fiber could not be separated from the effects of other dietary factors, i.e., lower contents of saturated fatty acids and cholesterol and higher intakes of fiber, potassium, and vitamins and minerals. The data that has become available since those reports were completed, as reviewed here by FDA and also as independently reviewed by outside experts (Ref. 40), do not provide sufficient evidence to warrant modifying or changing the conclusions reached earlier by the authoritative reports. Thus, FDA concludes that there is not sufficient scientific agreement, among experts qualified by experience and training, to support a health claim for dietary fiber and cardiovascular disease.

3. Public Health Importance

It is clear that cardiovascular disease, and particularly CHD, are major public health problems in the United States. There is also general agreement that dietary patterns that will lower serum cholesterol levels will also lower risk of these diseases. Dietary patterns high in fiber-containing foods; low in fats, saturated fats, and cholesterol; and associated with maintenance of desirable body weights are also associated with decreased risk of CHD. This association is the basis for the numerous dietary guidelines that recommend these types of dietary patterns. FDA has consistently supported these dietary guidelines and continues to do so. (With the proposed changes in the mandatory nutrition labeling regulations (see companion document published elsewhere in this issue of the **Federal Register**), consumers should be better able to obtain the information needed to select foods to help them meet these goals.)

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(1) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VI. Comments

Interested persons may, on or before (February 25, 1992), submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

List of Subjects in 21 CFR Part 101

Food labeling Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.71 is amended by adding paragraph (b) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(b) Dietary fiber and cardiovascular disease (insert cite and date of publication in the **Federal Register** of the final rule).

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

BILLING CODE 4160-01-M

Table 1

Dietary fiber and cardiovascular disease: Effects of soluble fiber on blood cholesterol in humans.

Study	Study Design	Subjects	Methods	Results	Comments
Abraham and Mehta, 1988 (Ref. 1)	Intervention, controlled diet	7 men, free living, with normal blood cholesterol (mean 187 mg/dL; range 132-240 mg/dL)	Subjects consumed controlled meals, based on usual diet, for 3 weeks followed by 3 weeks with psyllium (PSY) husks added to control diet in form of muffins, cookies, fruit drinks, and peanut butter. Gradual ↑ of psyllium starting with 7 grams/day to 21 g/day. Estimated soluble fiber (SF) intake from PSY - 16-19 g/day. Base diet: 30% kcals (kilocalories or Calories) from fat; 16% from protein; 54% kcals from carbohydrate. Cholesterol intake 300-400 mg/day. P/S = 1; total dietary fiber (TDF) 17 g/day.	After 3 weeks, total or serum cholesterol (TC) ↓16% (calculated) (significant (S)); LDL and HDL cholesterols also ↓ significantly. Subjects with the highest baseline serum cholesterol had the greatest TC reductions.	Subjects' cholesterol values were not stabilized, as the authors reported, when psyllium intervention was started. There was no control group during the intervention period. No data on body weight. The short test period limits ability to generalize to long term effects.
Anderson et al., 1988 (Ref. 8)	Intervention, randomized, parallel, double blinded, placebo controlled	26 men, ages 30-65; free living; normo- and hypercholesterolemic (188-314 mg/dL)	Subjects consumed regular diet for 2 weeks followed by adding psyllium (Metamucil) or cellulose (control), 3 times a day before meals (3.4 g fiber source/meal), to meals for 8 weeks. Dietary intakes monitored with 24-hour random records. 10.2 g/day of PSY provided an estimated 8-9 g of SF. Base diet: 40% kcals from fat; 20% kcals from protein; 40% kcals carbohydrate; <300 mg/day of dietary cholesterol.	From baseline, soluble fiber from psyllium: TC ↓15% (S); LDL ↓20% (S), and LDL/HDL ratio ↓15% (S). There were also significant differences between the placebo group and the psyllium group. No effect of PSY on HDL.	Psyllium was provided as an adjunct to the regular diet. Steady decline in TC over 8-week test in PSY group. No effect on body weight. Authors report compliance was excellent.
Anderson et al, 1990 (Ref. 4)	Intervention, randomized, self-controlled study on a metabolic ward	24 males, hypercholesterolemic, 37-69 years old. No hypocholesterolemic medications were allowed. 5 subjects exceeded desirable body weight by ≥ 20%.	Subjects consumed typical "American" diet for 7 days as a control period. Diet provided 38% kcals as fat; 19% kcals as protein; 43% kcals as carbohydrate; 420 mg dietary cholesterol; total kcals: 1729-1981/day. After 7 days subjects randomized into 3 groups for 21-day test period: Group A (n=6) received a single serving of canned beans (227 g) at noon, Groups B and C (n=9 each) received 2 divided servings of canned beans (227 g and 182 g, respec-tively). TDF / SF Control diet 13 g / 4 g Diets A and B 23 g / 8 g Diet C 23 g / 7 g	Total Serum cholesterol: ↓ 8-11.6% (S) compared to baseline control period in all three test groups. Overall, the LDL/HDL ratio remained similar to control ratios for groups A, B, and C. The interim TC values were lower (↓13-17% decrease from baseline) than the final values.	Each group experienced some weight loss (approximately 3 pounds). Calorie intakes were approximately 1800 kcals/day. TC was increasing towards baseline at end of 3-week test period. Short test period is a limitation of study design.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Anderson et al, 1990 (Ref. 6)	Intervention, randomized, self-controlled, cross-over on metabolic ward	12 men; 46-70 years old; hypercholesterolemic (210-326 mg/dL); body mass indices of less than 30; 5 subjects had evidence of cardiovascular disease	Subjects, randomized into 2 groups, consumed typical "American" diet for 2 weeks in addition to test or control cereal followed by crossover to other cereal for 2 weeks. Base diet provided 41% kcals as fat; 20% kcals as protein; 43% kcals as carbohydrate; 355 mg dietary cholesterol. One group started with addition of 56 g oat bran cereal to the diet; the other consumed 56 g of cornflakes (control). Total dietary fiber (TDF) and total soluble fiber (TSF) were: Oat bran cereal: TDF 21 g, TSF 7.4 g Cornflakes: TDF 15 g, TSF 4.5 g	Oat bran diet: ↓ TC 5.4% (S) compared to the corn flakes diet. LDL was lowered by 8.5%, and HDL was not significantly lowered.	The intake of carbohydrates, protein, fat and cholesterol were nearly identical in the two groups. Total dietary fiber varied between the two diets. No change in body weight. Short duration of test is a limitation.
Anderson et al, 1990 (Ref. 5)	Intervention, self-controlled, metabolic ward	10 men, ages 40-70 years; mild to high hypercholesterolemia (200-320 mg/dL); 13 enrolled. 3 dropped out: 2 for reasons unrelated to the study, 1 for non-compliance.	Subjects consumed a controlled diet for 7 days (control period) followed by a 3-week test period. Base diet: 30% kcals from fat; 15 kcals from protein; 55% kcals from carbohydrate; 450 mg/day dietary cholesterol; TDF 25 g/day. The test diet consisted of refined wheat bakery products, high in soluble fiber and fruits and vegetables. Bakery diet: TDF 25 g, TSF 9 g Baseline diet: TDF 25 g, TSF 3 g	No significant decrease in serum cholesterol on bakery diet; 8 had ↓TC; 2 had ↑TC. Significant (8%) ↓ in LDL. No significant change in the LDL/HDL ratio from control period.	Total fat was controlled but the P/S (poly-unsaturated fat/saturated fat ratio) increased somewhat in the bakery diet. Short time allowed for end-point measures to stabilize to the base diet; the subjects showed a ↓ in TC and ↓LDL during the 7-day control period. Constant body weight maintained by adjusting energy intake.
Anderson et al., 1991 (Ref. 3)	Intervention, randomized, controlled, metabolic ward study	21 men*, ages 38-73 years; hypercholesterolemic (total serum cholesterol: 190 to 347 mg/dL). Body mass indices less than 28.7; no medication for hypercholesterolemia. 1 subject failed to complete study. *14 men had hypertension, CHD, or CVD	Subjects consumed "typical" American diet for 7 days as a baseline (control), then randomized to oat bran (110 g oat bran/day) or wheat bran (40 g wheat bran/day) diets for 21 days; control and treatment diet identical in energy content, and nutrients, differing only in soluble fiber soluble fiber (oat bran) and insoluble fiber (wheat bran). Baseline diet: 41% of kcals from fat, 16% protein, 43% from carbohydrate, 450 mg cholesterol, 14 g/day TDF, 3 g/day SF. Brans were incorporated into muffins and cereals. Baseline diet: TDF 14, SF (bran) —, TSF (diet) 5-6 g/day Oat bran: TDF 34, SF (bran) 7.6, TSF (diet) 13.4 g/day Wheat bran: TDF 34, SF (bran) 1.3, TSF (diet) 7.8 g/day	TC %: OB ↓12.8*, WB ↓4.4 LDL %: OB ↓12.1*, WB ↓5.5 HDL %: OB ↓7.4, WB ↓3.1 *significant from baseline There was no change in the LDL-HDL ratio in OB group. No effect on HDL in either group.	Authors state the purpose of their study is to compare the effects of soluble fiber (from OB) and insoluble fiber (from WB) keeping TDF constant. Significant weight loss in both groups (about 1 kg from control values).

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Aro et al., 1984 (Ref. 9)	Intervention, double blind, crossover with placebo	14 men, ages 30-64, free living; severely hypercholesterolemic (301-402 mg/dL) and hypertriglyceridemia	Study designed with two 12-week crossover periods with an initial 4-week period on placebo diet and a 4-week washout between test periods. Subjects consumed normal diet (not defined); no dietary records were kept. Guar gum granules were mixed with water and taken before means; same for placebo. Placebo - wheat flour prepared similar to guar. Guar gum, 15 g/day (estimated 10.5 g soluble fiber) was added to baseline diet; it was consumed in 5-gram doses, after mixing with water, before the 3 main meals.	Guar gum: TC ↓ significantly after 6 weeks (15.3%) and by 8.2% between weeks 6 and 12 as compared to baseline. Most of the ↓ was in LDL (22% after 6 weeks and 14% after 12 weeks). Significant ↑ in mean TC from 6 to 12 weeks of guar gum supplementation. LDL/HDL ratio significantly lower in guar than placebo group. Placebo group experienced ↓ in LDL over the 12 weeks. No significant difference in TC and LDL between treatment and control after 12 weeks.	Weight maintained during the study; no dietary information given; no information on TDF or total SF intakes. Authors reported good compliance. The authors suggest that the attenuated effect of guar over time may reflect compensatory mechanisms in the body.
Beling et al, 1989 (Ref. 10)	Intervention, randomized, controlled	351 men and women, ages 20-60, hypercholesterolemic (total serum cholesterol between 200 and 300 mg/dL); not greater than 50% ideal body weight. 433 enrolled; 351 completed; attrition rates for groups 1,2, & 3 were 17%, 15%, and 24%, respectively. Major reason for attrition was inability to attend classes.	This was an 8-week study with 3 groups: Group 1: no dietary change Group 2: Step I diet, which was introduced during the first 4 weeks of the study and continued for 8 weeks Group 3: Step I diet, which was introduced during the first 4 weeks of the study, plus 2 oz oat cereal, which was added for weeks 5 through 8. Oatcor™, a concentrated oat bran cereal, was provided in 2 packets (1 oz each) to be consumed as a snack or cereal. The oat bran provided 10.6 g total dietary fiber per day; 7-8% total beta-glucans by weight. Group: % kcal - SFA (0 / Tx): 1: 12 / 10-11; 2: 11 / 6; 3: 12 / 7 (SFA = saturated fatty acids) % kcal - fat (0 / Tx): 1: 38 / 34-36; 2: 34 / 23; 3: 37 / 25-26 Total Dietary Fiber (0 / Tx): 1: 12 / 12-14; 2: 12 / 18-19; 3: 9 / 15-16	Total Serum Cholesterol (% Change from baseline) Group: 4 wks / 8 wks: 1: ↓ 2 / ↓ 2; 2: ↓10 / ↓ 8; 3: ↓12 / ↓12 LDL - cholesterol (% change from baseline) 1: ↓ 3 / ↓ 5; 2: ↓11 / ↓10; 3: ↓12 / ↓15 HDL - cholesterol (% change from baseline) 1: ↓ 1 / ↓ 1; 2: ↓ 6 / ↓ 3; 3: ↓ 8 / ↓ 8	Variable weight loss by treatment: group 1: 2 lbs; group 2: 4 lbs, and group 3: 6 lbs. There was no data on soluble fiber in diets. Not everyone responded similarly; both positive and negative responders and variation in magnitude of effect within treatment groups. Study was unblinded.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Bell et al., 1989 (Ref. 11)	Intervention, randomized, double blind, placebo controlled, parallel	75 men and women, 50th-90th percentile cholesterol (mean for placebo group was 162 mg/dL; for test group, 207 mg/dL); free living	This was a 20-week study with 12 weeks on step 1 diet, followed by 8 weeks of test fiber or placebo (cellulose). Psyllium (Metamucil powder) (3.4 g/meal) was taken 3 times a day before meals. Dietary intake was assessed with 3-day food records at weeks -6, 0, 8 and 16. Step 1 Diet: Fat 27-38% kcals SFA 7-10% kcals Cholesterol 160-200 mg/day T. Dietary Fiber 19-22 g/day Soluble Fiber 6 g/day Psyllium provided an estimated 8-9 g soluble fiber.	TC ↓4.2% ($) from baseline and ↓4.8% ($) from placebo; LDL ↓7.7% from baseline and ↓8.2% (both $) from placebo. LDL/HDL ratio: ↓10% from placebo and baseline ($). 30 subjects continued the intervention for 8 more weeks. Total and LDL cholesterol in the psyllium group tended to increase during the additional 8 weeks in both groups. TC values ↑ above baseline in placebo group; test group: TC ↑ but was still 7.7% lower than the placebo, but only 1.5% lower than baseline.	Psyllium was given as an adjunct to the diet, not in food form. Step 1 diet did not lower serum cholesterol significantly different in baseline TC values. Long term effectiveness remains a question based on evidence in this study of ↑ cholesterol during weeks 8-16 on psyllium. Both TC and LDL values ↑ above baseline in the placebo group; in test group TC ↑ and was only 1.5% lower than baseline, LDL ↑ and was 5% lower than baseline. Compliance was excellent in both groups.
Bell et al., 1990 (Ref.12)	Intervention, randomized, double-blinded, controlled	58 men; 24-69 years old; free living; with mild to moderate hypercholesterolemia (mean range 227-229 mg/dL)	Subjects consumed a Step 1 diet for 6 weeks; then randomly assigned to pectin-enriched, psyllium-enriched cereal, or corn flakes (control) groups for additional 6 weeks. Three-day dietary intake records taken at -6, 0, and +6 weeks. Cereals were added to Step 1 diet. NCEP step 1 diet: 30% kcals as fat, 55% carbohydrates, 15% protein; approx. 200 mg/day cholesterol. Total Dietary Fiber Baseline / Week 6 (g/day) Placebo 22 / 19 Pectin 21 / 16 Psyllium 23 / 22 Total Soluble Fiber Baseline / Week 6 (g/day) Placebo 7 / 6 Pectin 8 / 6 Psyllium 8 / 8	Total Cholesterol Diet Phase % from baseline / Cereal Phase % from diet phase Placebo ↓ 4 / ↑ 0.4 Pectin ↓ 4 / ↓ 2 Psyllium ↓ 3 / ↓ 6 * * significant from baseline and placebo LDL - cholesterol Diet Phase % from baseline / Cereal Phase % from diet phase Placebo ↓ 4 / ↓ 0.4 Pectin ↓ 5 / ↓ 4 Psyllium ↓ 4 / ↓ 6 * HDL - cholesterol Diet Phase % from baseline / Cereal Phase % from diet phase Placebo ↓ 6 / ↑ 2 Pectin ↓ 6 / ↑ 3 Psyllium ↓ 4 / ↓ 2	Excellent compliance reported. Dietary intakes were approximately same among groups, except for total dietary fiber. No change in weight.
Burr et al., 1989 (Ref.13)	Intervention on effects of diet on secondary prevention of myocardial infarction (MI), randomized, controlled	2,033 men, all recovered from MI; mean age 56 years; free living	A 2-year study. Three groups: (1) advice given to ↓ fat intake to 30% of calories and ↑ the P/S ratio to 1.0; (2) advice given to ↑ fatty fish intake to 2 servings/week; (3) advice given to ↑ cereal fiber (not defined) to 18 g/day. Cereal fiber intake in group 3 was twice that in subjects not given fiber advice. Normal diet of subjects was not defined.	No significant difference in total mortality between those given fiber advice and those not given fiber advice. No significant changes in serum cholesterol attributable to fiber advice.	Fiber is not separated into soluble and insoluble components; no assessment of confounding factors, including intakes of other nutrients (e.g., SFA), was provided.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Davidson et al., 1991 (Ref. 15)	Intervention, randomized, single-blinded, controlled. Purpose to evaluate the effectiveness of soluble fiber fraction, beta-glucan, in lowering serum cholesterol.	156 men and women, aged 30-65, randomized; 148 completed; free living hypercholesterolemic (230-319 mg/dL) with multiple risk factors. Data from only 140 were used, 8 dropped because of lack of compliance. Dropouts: placebo (3), OB-56 (2); OM-28(1); OM-84(1), and OB-84(1).	NCEP Step 1 diet given 8 weeks before randomization to test diet and during the test period. 6 weeks of intervention with oatmeal (OM)or oat bran (OB) in 28 g, 56 g or 84 g servings. 28 g farina as a control. After intervention 6 weeks of follow-up with no supplementation. Step 1 diet: fat: <30% kcal SFA: <10% kcals Groups TDF TSF OM 28 g 16 6 OB 28 g 17 6 OM 56 g 14 5 OB 56 g 20 7 OM 84 g 19 7 OB 84 g 22 7 Farina 28 g 15 0 4-day food records at baseline, week 3,6,12.	Group g. β Glu % TC % LDL 1. OM 28 1.2 -3.9 -5.8 2. OB 28 2.0 -2.7 -4.7 3. OM 56 2.4 -2.7 -3.5 4. OB 56 3.6 -9.5* -15.9* 5. OM 84 4.0 -7.1* -10.1* 6. OB 84 6.0 -6.9* -11.5* 7. FA 28 0.0 +0.6 +0.6 OM=oatmeal OB=oat bran FA=farina Glu=glucan *** Only these changes are significantly different from baseline.** The groups showed a decrease in total cholesterol and LDL at the higher levels of oat intake.	Lacked control group for each level of oats consumed. Body weight were stable.
Demark-Wahnefried et al., 1990 (Ref. 16)	Intervention, randomized	81 men and women, 20-65 years, hypercholesterolemic (mean of 271 mg/dL), free-living: 13 dropped out.	12 weeks of intervention on oat bran or processed oat bran cereal. Individuals given oat bran (OB) supplements, OB cereal, and a recipe book for fat-modified diets. One group consumed regular diet and did not get recipes. 50 g oat bran per day (estimated 3.7 g soluble fiber) as add-on to test group. 50 g OB and 42.5 g processed cereal had same amount beta-glucan. Diets: Group 1: low fat, low cholesterol diet Group 2: low fat, low cholesterol diet plus 50 g OB Group 3: regular diet plus 50 g OB Group 4: regular diet plus 42.5 g processed oat bran	Although there was a significant drop in serum cholesterol with all groups, there was no significant difference in the final serum cholesterol between any of the four groups. The low fat, low cholesterol control diet alone had the most marked drop in cholesterol (↓17%) from baseline.	Drop out rate is very high (16%). The study size is small; power to detect changes between groups is limited. Variable weight loss among group with the group consuming low fat diet plus oat bran experiencing the greatest weight loss (4-5%). Calorie intake varied from a mean of 1600 Cal/day for low fat, low cholesterol diet to 1900 Cal/day for oat bran. % changes from baseline in saturated fatty acids ranged from 22% for OB group to 51% for low fat, OB group.
Glassman et al., 1990 (Ref. 18)	Intervention	36 children with type IIa cholesterolemia (mean of 257.0 mg/dL).	8 months on Step 1 diet (10% kcals from SFA) (n=14); 1 month washout period, then 8 months on NY Medical Center modified saturated fat diet (fat 10% of kcals) and added soluble fiber from psyllium (PSY) (n=36). PSY was mixed with water twice a day. Children age 7 and older consumed 10 g psyllium (8-9 g soluble fiber estimated) per day; younger children consumed 2.5 g/day (estimated 2-2.5 g SF).	Total cholesterol and LDL ↓ significantly (18% & 23%, respectively) in test group on NY diet with psyllium. Total cholesterol and LDL decreased 6.7 & 8.8% (NS) on step 1 diet for the same duration. Nine obese children lost weight (2.8 kg).	Primary type IIa cholesterolemia is an inherited condition which causes extremely high serum cholesterol levels in children through a metabolic error in the breakdown of cholesterol. The study is not blinded, and there is no placebo.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Gold and Davidson, 1988 (Ref. 19)	Intervention, double blind	72 male and female medical students; 25-37 yrs old; free-living; normal cholesterol (mean 178 mg/dL)	This was a 4-week intervention study. Subjects consumed 2 muffins/day that contained test fibers (muffins were provided) along with their regular diet. 3-day food records were submitted. Subjects randomized into 3 groups and received muffins made with either oat bran, wheat bran, or a wheat/oat bran combination. Added soluble fiber (S.F.) and dietary fiber (D.F.) from muffins: S.F.* D.F. (g) oat bran 2.5 5.0 oat/wheat 0.9 5.3 wheat bran 0.33 5.5 *estimated	Oat bran: TC ↓5%* and LDL ↓9% *significant from baseline S.F. from combined oat/wheat and wheat: TC no change; LDL no significant decrease.	No assessment of the dietary intake before or during the test period. No data on total dietary fiber or total soluble fiber intakes in baseline and treatment diets.
Kahn et al., 1990 (Ref. 25)	Intervention, randomized, controlled.	16 men and women, age 51-54, hypercholesterolemic (215-314 mg/dL); some were diabetic. Free living	One group began immediate intervention on oat bran for 3 weeks; other group was the untreated control for 3 weeks, then they started the intervention for 3 weeks. This was followed by a 6-week washout period during which blood samples were taken. Test subjects consumed 80 g oat bran (estimated 6 g soluble fiber) per day, added to the diet as oat bran muffins (4 per day). Each muffin provided 112 Calories and 20 g oat bran. Subjects' usual diets were not assessed.	All groups, including the control group, had ↓ TC but there was no significant change in serum cholesterol values when the test group was compared to the control group. Results showed a significant ↓ in total cholesterol by 8% and LDL cholesterol by 10% from baseline when individual values were examined.	No dietary assessment before or during test. Subjects experienced some weight loss.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Keenan et al., 1991 (Ref. 26)	Intervention, randomized, controlled, double blind with crossover	145 men and women, ages 20-70; free living; hypercholesterolemic (207-267 mg/dL). 15% dropout after randomization.	Study designed with 3 periods (6 weeks each period): period 1: step 1 diet; periods 2 & 3: test periods. Test products were provided. 3 groups: control, wheat, and oat. The control group consumed step 1 diet for entire study period. 4-day food records were collected in week 5 of each period; baseline dietary intake taken by self-administered food frequency questionnaire. Step 1 diet: fat calories: <30% SFA calories: <10% Cholesterol: 240 mg/day 2 ounces of oat bran cereal and 2 ounces of ready-to-eat wheat cereal were test fibers. Oat bran: (3 g SF/day); Wheat cereal (1 gram SF/day)	Total cholesterol and LDL decreased in all groups during step 1 period (↓2.5-4%). Oat-wheat group had a further ↓ in TC of 2% (NS) on oat cereal, followed by a 6% ↑ in TC on wheat cereal. The wheat-oat group had no change in TC on wheat and a 3% decrease on oat. Control group had significant increase in TC back to baseline during test periods. Women under 50 found resistant to oat bran intervention. Control — TSF g/day — % Change in TC* Step 1 — 6.8 — ↓2.5-4 Step 1 — 6.2 — + Step 1 — 6.0 — + Oat-Wheat Step 1 — 6.7 — ↓2.5-4 Oat — 7.7 — N.S. Wheat — 6.1 — ↑ 6 Wheat-Oat Step 1 — 5.8 — ↓2.5-4 Wheat — 6.0 — N.S. Oat — 7.4 — ↓ 3 *Compared to beginning of respective treatment period.	Placebo was needed for diet only group. Control group initially dropped TC and then returned to baseline making it difficult to use as a control. Variability among groups in serum cholesterol levels at beginning of treatment periods.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Kesaniemi et al, 1990 (Ref.27)	Intervention, randomized, self-controlled, crossover	34 men, free living, normal serum cholesterol (223-238 mg/dL). Helsinki, Sweden; 3 were mildly hypertensive, 3 had gallstones, 1 had history of myocardial infarction, and 1 had maturity onset diabetes mellitus.	Purpose of study to evaluate cholesterol metabolism on high and low mixed-fiber diets. A 16-week study: 8-week low fiber period and an 8-week high fiber period. Diets for both groups were self selected. High fiber diet consisted of unpurified corn products, fruits, vegetables, salads, berries, fiber-cereal (made with oat flakes and guar gum and pectin) and graham biscuits (fortified with bran and carrots). Low fiber diet: avoid eating unpurified cereal products, vegetables, salads, fruits and berries. Low fiber period: 11.6 g per day mean intake total fiber (3 g of which is viscous fiber) High fiber period: 26.2 g per day mean intake total fiber (12.8 g of which is viscous fiber) 7-day food records were kept during week 8 of study.	High fiber diet: TC ↓5%, HDL ↓8% and LDL ↓7%. (all statistically significant)	Dietary intakes of total carbohydrate, energy and protein intake were lower on high-fiber diet. Fat intake did not differ significantly between the groups, but the high fiber diet did contain less total fat, with a higher polyunsaturated to saturated ratio. The high fiber group consumed significantly higher levels of vegetables, cereal, fruits, and berries, compared to the low-fiber group.
Kestin et al., 1990 (Ref. 28)	Intervention, randomized, double blind, controlled with crossover. Purpose to compare separate effects of three cereal brans (wheat, rice, oat) on plasma lipids	24 men, 29-61 years, mild to moderate hypercholesterolemia (186-293 mg/dL)	3-week control period prior to test; 4 weeks on each of 3 test diets; no washout. Test fibers, oat bran, wheat bran, rice bran, were provided as bread and muffins; control - low fiber white bread. Fiber supplements were added to individual's normal diet. **Test fibers:** Oat bran: 95 g/d; 5.8 g of soluble fiber per day. Rice bran: 60 g/d; 2.9 g of soluble fiber per day. Wheat bran: 35 g/d; 2.6 g of soluble fiber per day. **Base diet:** % fat calories: 31-37 % SFA calories: 12-13 Cholesterol: 250-300 mg/day TDF: Baseline: 11.2 g/day Test diet: 21 g/day SF: OB diet: 10.3 g/day RB diet: 7.2 g/day WB diet: 6.8 g/day Baselin: 5.7 g/day	Oat bran diet: TC ↓ 5% (significant) compared to baseline. The decrease was mainly in the LDL fraction; HDL increased from baseline in all bran diets. Rice and wheat brans did not cause significant lowering.	The amounts of soluble fiber and insoluble fiber in the three test diets were varied while total fiber was held constant. The oat bran group had higher soluble fiber than the rice, wheat or baseline.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Lampe et al., 1991 (Ref. 35)	Intervention, controlled, crossover	34 men and women (college students), normal cholesterol; free-living; mean age 27.1 years	Three fiber types (wheat bran, vegetable fiber, sugar beet fiber) were supplements to a controlled liquid base diet for three weeks each, with ≥10-day washout between test periods. Fibers were provided as breads and cereals. Base diet: liquid formula diet providing 35-37% of kcals as fat; 12-14% kcals as saturated fat; 558 mg cholesterol/day; fiber free. Wheat bran: 10 g and 30 g/day (1.1 g and 2.6 g soluble fiber (SF), respectively) Vegetable fiber: 10 g and 30 g (2.7 g and 5.2 g SF) Sugar beet: 30 g (8.2 g SF)	change from baseline TDF g/day / SF / %TC Fiber free 2 1 ↓3 10 g WB 11 1 ↓4 30 g WB 29 3 ↓1 10 g VF 15 3 ↓4 30 g VF 37 5 ↓8* 30 g SBF 30 8 ↓14* WB = wheat bran; VF = vegetable fiber SBF = sugar beet fiber *Statistically significant Changes in LDL were similar.	Effect of fiber in a liquid base diet may not reflect fiber effect in regular foods. SFA and cholesterol intakes were higher on fiber free than test diets. Short test periods.
Levin et al., 1990 (Ref. 37)	Intervention, randomized, double blind	58 men and women, 21-70 years old, free living; mildly hypercholesterolemic (235-245 mg/dL)	8 weeks of diet therapy on a step 1 diet (25% kcals as fat; P:S 1.0; cholesterol <200 mg/day, TDF 21-23 g/day; TSF 6.5-8.5 g/day) followed by 16 weeks treatment with psyllium (Metamucil) or cellulose as placebo. PSY or cellulose were consumed in fluids twice a day before meals. TSF in PSY (10.2 g/day) group an estimated 15 g/day.	Psyllium diet: TC ↓6% and LDL ↓9% (both significant) from baseline; placebo group, no change.	The psyllium group showed a small drop (not statistically significant) in dietary fat intake, while the placebo showed no change. There was some weight loss in the psyllium group. Subject compliance was 95%.
Little et al., 1990 (Ref. 42)	Intervention, controlled	184 men, ages 58-61; free living, treated for hypertension and hypercholesterolemia (240-267 mg/dL)	8-week intervention with five groups: Group 1: no dietary change Group 2: high fiber Group 3: low sodium Group 4: low fat (25% cal) Group 5: low fat, high fiber Fiber was not defined. Total dietary fiber, including soluble and insoluble, was 40-45 g/day.	Low fat diet: TC ↓4.7% (S) compared to baseline; Combination low-fat, high fiber diet: TC ↓4.1% (S) compared to baseline; LDL was not ↓ significantly in either diet group and TC lowering for these two groups were not different from each other. High fiber diet: TC ↑1% (NS).	Changes in serum cholesterol were same for low fat diets and for low fat and high fiber diet. Authors suggest low fat was the effective nutrient.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Lo and Cole, 1990 (Ref. 43)	Intervention, randomized, double blind, crossover	12 men, 8 women ages 27-60; free living; normo- and hypercholesterol-emic (210-279 mg/dL)	12-week study: two 6-week test periods with additional 3-week rest between periods. Soy cotyledon fiber, made into cereal and bread, was supplemented in 3 divided portions to the subjects' normal diet. Soy: 15 g dietary fiber: 4.3 g of soluble fiber and 13 g of insoluble fiber per day placebo supplements: 4.5 g dietary fiber, 1.2 g soluble fiber, 3 g insoluble fiber. Dietary intake assessed from 3-day dietary records. Diets: Placebo / Soy % kcals fat: 32 / 36 Cholesterol: 290 mg / 270 mg TDF: 13 g / 24 g	After first 6 weeks: Soy group: TC ↓8% (S), LDL ↓7% (S). Placebo group: TC ↓2%, LDL ↓5% (S). After crossover, subjects on soy had a non-significant reduction of cholesterol. The greatest cholesterol reduction occurred within the first six weeks.	This study has a placebo group, is double-blinded and randomized. Fat intake in the two groups were borderline significantly different; neither the saturated nor polyunsaturated intakes are measured. The authors did not keep total dietary fiber constant between the groups. Results varied by order of treatment.
McIntosh et al., 1991 (Ref. 44)	Intervention, randomized, crossover; purpose - to compare barley vs wheat foods and their influence on serum cholesterol levels.	21 men, aged 30-59; free living, mild to moderately to high cholesterol (209-270 mg/dL); South Australia	3-week baseline period followed by 4 weeks on each diet. No washout between test periods. Barley and wheat foods were provided. Barley (high in β-glucan) was tested against wheat; dietary intake assessed from 24-hour recall every third day throughout study. Barley diet: 38 g DF, 13 g SF, 25 g insoluble fiber (IF), 8 g β-glucan. Wheat diet: 38 g DF, 13 g SF, 25 g IF, 1.5 g β-glucan. Base diet: 31-35% kcals as fat, 25-26% kcals as saturated fat, P/S 1.6, TDF: 21 g/day; SF: 7 g/day.	Compared to baseline: barley: ↓TC about 2% and LDL ↓1% (both NS); wheat: TC ↑4% and LDL ↑6%. The group consuming barley during the first test period had no difference in serum total cholesterol, then a small increase in cholesterol on wheat. Those consuming wheat first, then barley showed increased serum total cholesterol, then decreased cholesterol on barley.	The authors, in their analysis, controlled statistically for the P/S and fibers. Results difficult to interpret since wheat was used as a control. Comparison to baseline cholesterol shows only a slight effect of barley on TC. The authors account for the difference in response between groups by suggesting that 4 weeks was too short a test period.
McIvor et al., 1985 (Ref. 45)	Intervention, controlled	8 men and women, obese, ages 45-50, with non-insulin dependent diabetes, free living; normal cholesterol (mean 222 mg/dL).	6-month intervention with gradual phase-in of guar gum within first 4-8 weeks. Guar gum added to subjects' normal diets in granola-type bars. Ss began with 1 granola bar/day and increased to 4 bars/day. These were eaten with meals. Control group consumed granola bars without guar gum; no dietary assessment of normal diet. Guar gum intake: up to 32 g/day (4.8 bars/day - each bar had 6.6 g guar gum and estimated 22 g SF).	After 6 months, serum total cholesterol was not significantly different from baseline. LDL and HDl components were not discussed.	Diet was not monitored.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Newman et al., 1989 (Ref. 50)	Intervention, randomized, single blind; purpose - to compare barley with wheat sources of fiber.	14 men, 35 years or older, free living, normal serum cholesterol 141-247 mg/dL	4 weeks of pretreatment with normal diet (see below) followed by 4 wks of test. Cereal and baked goods containing hulless barley (10% β-glucan) were provided for high fiber, high β-glucan group. Cereal and baked goods containing 75% wheat flour/25% wheat bran (0.5% β-glucan) for low fiber, low β-glucan group. 3-day dietary history recorded last 3 days of study. Pre-treatment diets Groups Wheat / Barley % fat kcals 35 / 42 TDF, g 7.6 / 4.9 Final diets % fat kcals 34 / 35 TDF, g 46.4 / 44.0	The wheat group had a significantly higher total cholesterol and LDL at the end of the study than at the beginning. The barley group showed no significant change from the beginning to the end of the study.	Total fat intake was significantly different between the groups initially. Over the course of the study, there is a large ↓ in the test group's fat intake, and no change in the wheat group.
Shutler et al., 1989 (Ref. 53)	Intervention, randomized, self-controlled, not blinded	13 non-smoking men, 18-26 years old; free living; normal cholesterol (mean of 196 mg/dL)	A 42-day study: 2 weeks test with canned beans added to normal diets, followed by a 3-week wash-out period, then a 14-day control with spaghetti, followed by subjects' regular diets for 20 or more days. Beans: 1 can (450 g) per day (soluble fiber not assessed); Spaghetti: 1 can (440 g) per day. 3-day food diary kept for the pre-trial, bean, and spaghetti periods. Diets Baseline / Beans / Spag. % fat kcals 36 / 31 / 33 P:S 0.4 / 0.4 / 0.4 Chol, mg 290 / 208 / 174 TDF, g 25 / 60 / 24	Test group, while eating beans: TC ↓12% (S); and HDL ↓15% (S) compared to baseline. After a washout period, the same group, substituting spaghetti for beans showed no effect in cholesterol reduction compared to baseline.	Sat. fat and PUFA (polyunsaturated fatty acids) changes in intake during the test periods were similar. No data on soluble and insoluble fibers. Short test period is a limitation of study.
Stewart et al., 1991 (Ref. 55)	Intervention	Test: 175 men and women, mean age 77 years. Treatment group was selected from ambulatory elderly participants attending a health screening and who had been using psyllium as a laxative or stool softener for at least 1 month. The control group consisted of 741, mean age 75, and was selected from program participants not using psyllium.	The test participants had to be taking psyllium (PSY) for at least one month to one year. The intake of PSY varied from less than 9 g (soluble fiber estimated at 7-8 g) per day to over 19 g (SF estimated at 15-17 g) per day. The regular diet of the participants was not assessed.	Those taking greater than 15-17 g of soluble fiber from psyllium per day had a ↓4.1% in TC (significant). Those taking less than 8 g of soluble fiber from psyllium had no significant change in TC. Comparing taking any amount of psyllium to taking none, did not show a significant difference. intake of PSY was significantly correlated with change in serum cholesterol.	Some selection bias may have occurred since the test group included only regular users of bulk laxative and the control group only regular non-users. The quantity of the psyllium test intake was not controlled. Treatment group were older than controls (77 vs 55 years).

Study	Study Design	Subjects	Methods	Results	Comments
Superko et al., 1988 (Ref. 56)	Intervention, randomized, single blind with crossover	50 men; aged 39-63; free living; mild to moderately hypercholesterolemic (205-282 mg/dL)	An 8 week study with 3 groups: test group consumed medium-viscosity guar gum (liquid or solid form) for 4 weeks on one diet, then crossover to other form of guar for 4 weeks. Second group: high viscosity guar - consumed in solid form for 4 weeks only. Control group consumed placebo for 8 weeks. Diet was self-selected except for fiber supplements and placebo. Guar gum intake: 15 g/day, (estimated soluble fiber of 10.5 g/day). Placebo intake: 15 g/day. 4-day dietary records were obtained at baseline and at end of each test period.	At 4 weeks: Medium viscosity guar group TC ↓10% (S) and LDL ↓14% (S) from baseline. High viscosity guar group TC ↓15% (S) and LDL ↓18% (S) from baseline. Placebo group TC ↓4% from baseline (NS) and ↓7% drop in LDL (NS). At 8 weeks: the guar groups' total cholesterol levels increased during the second half of the study. Net effect over the 8 weeks of the study: a NS difference between guar groups and the placebo.	Study is blinded and fat intake was measured and assessed for differences between groups. Results differed between the first 4 weeks and the second 4 weeks of guar-supplemented diets making it difficult to draw conclusions about the effect of guar gum on serum cholesterol.
Swain et al., 1990 (Ref. 57)	Intervention, randomized, double blind, crossover	4 male, 16 female hospital employees; 23-49 yrs old; free-living; normal cholesterol: mean 185 mg/dL	6-week test period followed by a 2-week washout, then crossover to other diet for 6 weeks. Oat bran and wheat bran were fiber sources added to subjects' regular diets. Dietary intake assessed with food frequency questionnaire; 4-day food records kept during 5th test week of each test period. Oat bran: 15 g soluble fiber (S.F.)/day Wheat bran: 3.7 g S.F./day Base diet Fat: 31% of kcals; high fiber period had 35% kcals as fat, which came from unsaturated fat in oat bran supplements. Authors contend the additional fat does not affect serum cholesterol.	High fiber: total serum cholesterol (TC): ↓7.5%*+; LDL: ↓9.1%*+ Low fiber: TC ↓7.1%*+; LDL: ↓6.4%*+ *significantly lower from baseline +no difference between groups Authors proposes that substitution of either wheat or oat fiber for dietary saturated fat causes the decrease in TC.	No placebo. Study results limited by small number of subjects and short test period.
Taneja et al., 1989 (Ref. 58)	Intervention, controlled crossover	11 Indian girls, 16-18 years old; free living, normal cholesterol (mean 182 mg/dL)	A 6-week study: 3 weeks on low fiber foods; 3 weeks on high fiber foods. Controlled low fiber diet: refined cereals, dehusked pulses, potatoes, milk, curd, eggs, low fiber vegetables. High fiber diet: same diet with added isagbol husks. Isagbol husks - 25 g (estimated 20-22 g SF) per day.	Higher fiber diet: TC significantly lower (↓7%) compared to low fiber diet. LDL and HDL components are not discussed.	The initial TC levels of each group are not reported. In addition, the fat intake is lower in the high fiber group, and soluble and insoluble components of the isabgol husk diet are not reported.

Study	Study Design	Subjects	Methods	Results	Comments
Tuomilehto et al., 1988 (Ref. 59)	Intervention, placebo-controlled, crossover	23 men and women, 37-67 years, free living; severely hypercholesterolemic (range 309-553 mg/dL); 4 had type II diabetes, 8 had hypertension, five had familial hypercholesterolemia.	A 1-year study: 1 month placebo period at start, followed by 50 weeks of test with guar gum, then 4 weeks of placebo period. Subjects told to mix guar gum granules with water and take before a meal or mix granules with food. Placebo: granulated wheat flour consumed the same as guar. Guar and wheat granules were added to Ss normal diet (not defined). Guar gum: 15-30 g/day (estimated 10.5-21 g soluble fiber) Wheat flour: 15 g/day Dietary intake monitored by food diary for 4 days before test period and at weeks 17 and 33.	Maximum TC ↓18% (S) after 8 weeks; then ↑ to a final TC level (347 mg/dL) significantly lower (10.5%) than baseline. During final placebo month, serum cholesterol ↑ to pretreatment level. Higher intakes of soluble fiber (14-21 g/day) from 20-30 g guar were not well tolerated. At 34 weeks: LDL ↓15% (S).	Subjects had severely high TC and many with other medical problems. There was some weight loss (4.4 lbs) which was not statistically significant, but must be considered when interpreting the results. Diet was not defined, nor was soluble fiber intake defined.
Van Horn et al., 1988 (Ref. 68)	Intervention, randomized, controlled with crossover	236 men and women, ages 30-65, free living; normo-cholesterolemic (163-247 mg/dL)	A 12-week study: 4 weeks on control diet and 8 weeks on test diet. Both test and control groups consumed the Phase II American Heart Association (AHA) diet throughout the study. The test group consumed 56 g oatmeal/day for for 8 weeks. Phase II AHA diet: total fat: ≤ 30% calories; equal distribution among saturated, mono-unsaturated, and poly-unsaturated fatty acids. Dietary cholesterol: 250 mg/day. 56 g per day oatmeal: 8.4 g dietary fiber and 4.2 g of soluble fiber.	Serum cholesterol levels at baseline and after 4 weeks on the AHA diet were similar for both groups. After 4 weeks: test group had significantly lower serum cholesterol than control group. After 8 weeks: no significant difference in total serum cholesterol between groups. Changes in LDL paralleled changes in total cholesterol. Similar and nonsignificant increases occurred in HDL in both groups. Subgroup analysis showed that subjects in test group with highest baseline serum cholesterol had greater reductions in cholesterol. No change in LDL. The low fat diet was effective in lowering serum cholesterol	No beneficial effect of soluble fiber from oatmeal on serum cholesterol after 8 weeks.

TABLE I--CONTINUED

Study	Study Design	Subjects	Methods	Results	Comments
Van Horn et al., 1991 (Ref. 65)	Epidemiological cross sectional survey	5,111 men and women, 18-30 years; normal cholesterol levels	3 diets: a) lower SFA, high PUFA; b) lower SFA and fish; c) lower SFA and cereal	Dietary fiber is inversely and significantly correlated with TC and LDL; and positively and significantly correlated with HDL in 25-30 year-old white women.	Dietary analyses did not assess soluble and insoluble components of dietary fiber. Also, the study did not control confounders such as smoking, alcohol use, exercise, or fat intake differences between groups. Single samples for cholesterol analysis could not correct for intraindividual variability. Statistical significance was not adjusted for multiple comparisons.
Van Horn et al., 1991 (Ref. 69)	Intervention, randomized, controlled	80 men and women, mild to moderate hypercholesterolemia (213-285 mg/dL)	Two groups: control group consumed regular diet; test group consumed regular diet plus instant oats (2 packets/day - 57 g). TDF SF Insol. F Oatmeal 5.6 g 2.2 g 3.4 g	The test group, while supplementing their diet with oatmeal: TC ↓6% (S); both the LDL and the LDL/HDL ratio ↓9%. The control group showed no change.	The study was not blinded; the test group reduced their intake of total fat, saturated fat and dietary cholesterol, and may have made other lifestyle changes.

Food Labeling: Health Claims and Label Statements; Folic Acid and Neural Tube Defects

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing not to authorize the use on the label and labeling of foods, including dietary supplements, of health claims relating to an association between folic acid and reduction in risk of neural tube defects. FDA has reviewed the scientific data in conformity with the requirements of the Nutrition Labeling and Education Act (the 1990 amendments) and has tentatively concluded that there is not a sufficient basis to support the use of health claims relating to this topic. FDA also reviewed recently published results of a large intervention trial of effects of supplements containing very high levels of folic acid in women who, because of histories of neural tube defect-complicated pregnancies, were at high risk of recurrences of these specific birth defects in subsequent pregnancies. Currently there is not significant agreement among qualified experts that intakes of folic acid lower than those studied in this intervention trial will have the same effect as that observed with very high intakes.

Additionally, at this time, there is no significant agreement among qualified experts that folic acid supplementation of women at much lower risk of occurrence of neural tube defect-affected pregnancies will reduce the risk of such a complication. However, the results of the recently published intervention trial are causing some qualified experts to reevaluate the preexisting evidence. FDA will consider all developments in this regard and reflect such developments in any final rule that it issues. FDA has tentatively concluded that claims on foods, including dietary supplements, relating to folic acid and reduction in risk of neural tube birth defects are not justified.

DATES: Written comments by (January 27, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Jeanne I. Rader, Center for Food Safety and Applied Nutrition (HFF-268), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-472-6067.

SUPPLEMENTARY INFORMATION:

I. Background

A. The 1990 Amendments

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101-535), which amended the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary), and FDA by delegation, to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this issue of the Federal Register is a proposed rule to establish general requirements pertaining to the use of health claims on food labels and in labeling that characterize the relationship of nutrients, including vitamins and minerals, herbs, or other nutritional substances (referred to generally as "substances") to a disease or health-related condition. In this document entitled "Food Labeling: General Requirements for Health Claims for Food: Proposed Rule (the companion document), "FDA has tentatively concluded that such claims would only be justified for substances in dietary supplements as well as in conventional foods if the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner that is consistent with generally recognized scientific procedures and principles) supports a claim; and if there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims about such support.

The 1990 amendments also require (section 3 (b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)), that within 12 months of enactment, the Secretary issue proposed regulations to implement section 403(r) of the act, and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including folic acid and neural tube defects, meet the requirements of the act. In this document, the agency considers whether a claim on food or food products, including conventional foods and dietary supplements, on the relationship between folic acid and neural tube defects would be justified under the standard proposed in the companion document.

FDA has followed the general concepts and criteria proposed in the companion document in considering whether to propose to authorize the use on the labels and labeling of food of health claims for folic acid and neural tube defects. In the companion document, FDA has proposed that, in evaluating whether support exists for a health claim, it will consider the levels and safety of a nutrient within the context of its use in the daily diet. Before a health claim for a particular nutrient will be authorized, it is necessary that the nutrient be safe and lawful for use in food at the level found to have an effect on a disease or health condition.

The topic of folic acid and neural tube defects involves a substance which has recognized uses both as a component of food and of drugs. The agency has looked at all data relevant to this topic whether the data involved tests at dietary levels or at therapeutic levels. The agency thought this necessary to ensure the completeness of its review. However, the agency emphasizes that this proposal is only about whether a claim has been justified for folic acid on food. A component of food must be safe in the context of the daily diet. On the other hand, drugs may be used even if they present questions of safety to the general population, and even to the population being treated, on the basis that there is a benefit from its use that outweighs the potential risk.

B. Folic Acid and Neural Tube Defects: Public Health Aspects

Congenital malformations are structural abnormalities that are present at birth. Several specific malformations of the central nervous system (CNS) are referred to as "neural tube defects" because the brain and spinal cord develop within the neural tube. The neural tube forms early in fetal life, between the 18th and 20th days of pregnancy, and closes between the 24th and 27th days of pregnancy. Neural tube defects include a wide range of abnormalities of the CNS. They may be isolated malformations or may occur in association with other nonneural congenital malformations.

Anencephalus and spina bifida account for about 90 percent of neural tube defects (Ref. 1). Anencephalus is an abnormality in which there is a virtual absence of the forebrain and skull. Most anencephalic infants are stillborn. Live-born anencephalic infants may survive for only a few days. Spina bifida is a general term describing various developmental abnormalities characterized by defective closure of the bony encasement (the vertebrae) of the spinal cord. The spinal cord and nervous system tissues may protrude through openings resulting from failure of the vertebrae to form normally. Infants born with spina bifida may lack normal function below the level of the defect because of damage to specific nerves.

Anencephalus and spina bifida are more common in Caucasian populations than in other racial groups. Reports of prevalence per 1,000 births in Caucasian populations have yielded the following estimates for anencephalus and spina bifida, respectively: Wales, 3.6, 4.1; Scotland (Glasgow), 2.8, 2.8; Northern Ireland, 3.1, 3.3; Hungary (Budapest), 1.1, 1.6 (Ref. 2). In contrast, prevalence of anencephalus and spina bifida in Japan has been reported to be 0.43 and 0.08, respectively, per 1,000 births (Ref. 2). Rates of neural tube defects in hospital series in northern China, however, are among the highest yet reported and range between 5 and 13 per 1,000 births (Ref. 2a).

The incidence rate of neural tube defects at birth has been reported to vary a wide range of factors, including genetics, geography, socioeconomic status, maternal birth cohort, month of conception, race, nutrition, and maternal health including maternal age and reproductive history. Epidemiologic evidence indicates that there is a strong genetic component involved in neural tube defects (Ref. 3). This genetic component is well-recognized, and familial recurrence patterns are the single greatest risk factor for neural tube defects, although studies in humans have not as yet localized the responsible genes. Carriership for inborn (genetic) errors of homocysteine (a metabolic product of methionine; an intermediate in the synthesis of cystine) metabolism has recently been proposed as a risk factor for having an infant with a neural tube defect (Ref. 4).

In the United States, neural tube defects affect approximately 1 in 1,000 infants at birth (Ref. 2) (i.e., the occurrence rate is approximately 0.1 percent). Occurrence rates are about 4 in 10,000 infants at birth (0.04 percent) in low-risk areas. For example, within the United States, the available hospital data and community surveys show that rates are highest in the northeast and lowest in the west, with anencephalus rates of about 0.5 per 1,000 (0.05 percent) in Iowa and Los Angeles (Ref. 2).

The number of first occurrences of neural tube defects exceeds the number of recurrent events. The great majority of families having an anencephalic or spina bifida infant will experience only one such affected pregnancy. A small minority of about 5 percent, however, will have more than one affected infant (i.e., a recurrence) (Ref. 5). Thus, the risk of having an infant with a neural tube defect is much higher among women who have had a previous pregnancy complicated by a neural tube defect than among women who have not had such a complication. Among women with histories of previous neural tube defect-complicated pregnancies, rates for recurrence of such defects have been estimated to be as high as 2 to 10 percent compared to occurrence rates of about 0.1 percent in the general population (Ref. 3). The pattern of recurrence of these defects is that expected of a polygenic (i.e., caused by several genes) trait. Data from the most recent report of the National Birth Defects Monitoring Program of the Centers for Disease Control (CDC) show decreasing trends for anencephalus and spina bifida between 1979 and 1987 in the United States (Ref. 6).

The striking geographical variations in prevalence at birth of anencephalus and spina bifida have not been adequately explained. For example, the range of prevalence rates in the United States and Canada is very large, with the highest prevalence rates found in the eastern portions of both countries. Additionally, the relatively low prevalence rates in western Canada (British Columbia) have been stable over time, in contrast to the higher rates in eastern Canada which have shown large secular variations similar to trends in the British Isles (Ref. 2). These observations suggest the action of fairly stable genetic factors, with higher but less stable rates possibly caused by the interaction of varying environmental factors with stable genetic factors (Ref. 2).

Maternal health, for example, febrile illness (Refs. 1, 7, and 8) and maternal use of certain drugs also have an effect on the development of neural tube defects. There is an increased incidence rate of malformations (including neural tube defects) among infants of diabetic mothers (Ref. 9). Therapeutic use of valproic acid, an anticonvulsant drug, is associated with markedly increased risk of neural tube defects (Ref. 10, 11, 12, and 13).

Epidemiologic studies suggest that factors associated with acute or chronic poverty also play a role in modifying the incidence rates of neural tube defects. Observational studies in humans suggest that poor maternal nutrition, which is among a number of factors associated with poverty, may increase the risk of neural tube defects. For example, in the United Kingdom, mean values for blood levels of a number of vitamins have been reported to be most satisfactory in women in the highest social classes (Ref. 14). Blood concentrations of several vitamins were reported to be lower on average in women who subsequently gave birth to infants with neural tube defects than in women who did not (Ref. 14). Such evidence is relatively nonspecific, however, since dietary deficiency of one nutrient is frequently correlated with deficiencies of other nutrients.

Maternal nutritional status around the time of conception (the "periconceptional period") is of special concern because, as stated above, the neural tube forms and closes very early in embryogenesis (Ref. 3). The periconceptional period, however, has not been precisely defined. The National Academy of Sciences (NAS) suggested in its 1990 report that this period or interval extends from 1 to 3 months before conception to week 6 of gestation (Ref. 3).

The hypothesis that nutritional factors might be involved in causing some human neural tube defects is based on findings from several types of studies. These include: (1) animal studies in which deficiencies of some vitamins during pregnancy (such as vitamin B_{12}, vitamin B_6 and pantothenic acid) produced a variety of fetal abnormalities, including neural tube defects (Ref. 1); (2) epidemiology studies of neural tube defects in humans that suggest a link with nutrition because of variations in prevalence with social class, dietary habits, and season (Ref. 9); and (3) clinical observations of congenital malformations including neural tube defects in offspring of women who were given an antifolate drug (a drug which alters folic acid status by interfering with absorption, metabolism, or functions of the vitamin) to test its efficacy as an abortifacient.

Among the nutrients that may have a role in development of neural tube defects, folic acid has received the greatest amount of attention because of observational studies in humans and because of the well-recognized roles of this vitamin in cell division and growth.

Folic acid is essential for humans. Folate compounds occurring naturally in foods are in a reduced pteroyl form. Folates occurring in plant and animal cells contain two to eight additional glutamic acid molecules which are linked to the glutamate end of the folate molecule. The folylpolyglutamates which occur in foods are broken down to the monoglutamate forms in the intestine. Commercially available folic acid (pteroylglutamate) is in an oxidized state relative to its occurrence in foods.

Insufficient quantities of folate in the diet lead to impaired cell multiplication and alterations in protein synthesis. These effects are most noticeable in rapidly growing tissues. Abnormalities of rapidly dividing cell populations (for example, those of the gastrointestinal tract and bone marrow) are among the most notable results of folate deficiency because of the essentiality of this vitamin for synthesis of deoxyribonucleic acid.

Determinations of folate in serum and in red blood cells are commonly used to assess folate status. Red blood cell folate concentrations are considered to be a better index of long-term folate status than are measurements of serum folate. Folic acid administered orally is effective for the treatment of megaloblastic anemias of nutritional origin, and those that may develop in women during pregnancy, and those that may develop in infants and children. Pregnancy increases the need for folic acid among other nutrients because of the need of the mother to maintain adequate nutrition and to meet the nutritional requirements of the rapidly developing fetus.

The Medical Research Council of the United Kingdom recently reported (Ref. 15) that periconceptional supplementation of women at high risk of recurrence of neural tube defect-complicated pregnancies with 4 milligrams (mg) folic acid per day significantly reduced the rate of such recurrences. In response, CDC issued guidelines (see section II A. below) for physician-directed use of high doses of folic acid by women who, because of histories of neural tube defect-complicated pregnancies, are at high risk of recurrences of these specific birth defects in subsequent pregnancies (Ref. 16). FDA regards the marketing of folic acid at the dosage and for the use recommended in the interim CDC guidelines (Ref. 16) to require an approved new drug application (NDA). No NDA has been approved by FDA for folic acid for prevention of neural tube defects.

C. Folic Acid: Regulatory History

FDA has promulgated regulations describing uses of folic acid as a dietary supplement and as a drug. These designations are dependent on the intended uses of this vitamin. Section 172.345 (21 CFR 172.345) provides for the use of folic acid in dietary supplement preparations. Preparations containing folic acid in excess of the permitted food additive level (see below) are regulated as drugs and are available with a prescription.

FDA evaluated the use of folic acid as a drug in the Federal Register of April 9, 1971 (36 FR 6843) in response to reports received from NAS on the therapeutic uses of folic acid. The agency concluded that folic acid administered orally or parenterally is effective for the treatment of megaloblastic anemias of tropical and nontropical sprue, those of nutritional origin, and those which may occur during pregnancy, infancy, and childhood (36 FR 6843). The agency found that administration of folic acid alone is improper therapy in the treatment of pernicious anemia and other megaloblastic anemias where vitamin B_{12} is deficient (36 FR 6843) because such treatment may mask the symptoms of vitamin B_{12} deficiency. FDA also concluded that there is no evidence that doses of folic acid greater than 1 mg daily have greater efficacy in treatment of megaloblastic anemias than do those of 1 mg (36 FR 6843).

Folic acid is an approved food additive subject to the limitations on use set forth in the food additive regulation § 172.345. Folic acid (folacin) may be safely added to a food for its vitamin properties, provided the maximum intake of the food as may be consumed during a period of 1 day, or as directed for use in the case of a dietary supplement, will not result in daily ingestion of the additive in excess of 0.4 mg for foods labeled without reference to age or physiologic state. When age or the conditions of pregnancy or lactation are specified, the regulation provides that the level of ingestion shall not exceed 0.1 mg for infants, 0.3 mg for children under 4 years of age, 0.4 mg for adults and children 4 or more years of age, and 0.8 mg for pregnant or lactating women (21 CFR 172.345).

D. Evidence Considered in Reaching the Decision

The agency has reviewed all relevant scientific evidence on folic acid and neural tube defects. The scientific evidence reviewed by the agency included all human studies considered in "The Surgeon General's Report on Nutrition and Health" (Ref. 21), and the United States Department of Agriculture's and the Department of Health and Human Services' "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 22). The other reviews conducted by widely recognized scientific bodies that FDA considered were NAS' "Diet and Health" (Ref. 23), the National Research Council's "Recommended Dietary Allowances" (Ref. 24), the NAS' "Nutrition During Pregnancy" (Ref. 3), and the Life Sciences Research Office's (LSRO) "Folic Acid and Neural Tube Defects" (Ref. 25). The agency updated the conclusions reached by these documents by reviewing all human studies that appeared in the literature subsequent to these documents and all new review articles. The agency also considered the results of animal studies to the extent that they clarified human studies or suggested possible mechanisms of action.

To assure that its review of relevant evidence was complete, FDA requested, in the Federal Register of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas identified in section 3(b)(1)(A) of the 1990 amendments. The topic of folic acid and neural tube defects was among the 10 subjects on which the agency requested information.

E. Comments in Response to FDA Request for Scientific Data and Information

In response to the March 28, 1991 notice in the Federal Register, FDA received 12 comments to the docket for folic acid and neural tube defects from manufacturers and suppliers of vitamins to the food and dietary supplement industries, trade associations of nutritional supplement manufacturers, national professional organizations of nutritionists and public health nutrition directors, and the government of Canada. The comments dealt with the issue of folic acid and neural tube defects as well as with the goals and requirements of the 1990 amendments in general. FDA reviewed all of the documents, including letters, press releases, scientific articles, review articles, and recommendations included in submissions that it received. The data submitted in scientific articles were included in the agency's review of the scientific literature.

Among the comments received were three from manufacturers and suppliers of vitamins and two from trade associations of nutritional supplement manufacturers. The submissions from these groups stated that there is sufficient evidence to provide claims for

periconceptional multivitamin (including folic acid) supplementation for reduction in risk of neural tube defects and possibly cleft lip/palate. One comment recommended a Recommended Dietary Allowance (RDA) RDA-level multivitamin supplement for all women of child-bearing age.

One comment from a manufacturer of vitamins recommended multivitamin supplementation for 3 months preceding through 3 months following conception. The comment pointed to several reasons for supplementation during this interval including: (a) The available data; (b) almost risk-free nature of such supplementation; (c) low cost of such supplementation; and (d) economic aspects of care and treatment of infants born with severe birth defects. Another comment from a trade association of nutritional supplement manufacturers stated that there is no risk associated with use of a multivitamin supplement with folic acid with or without minerals by women contemplating pregnancy.

The "almost risk-free" or "no risk" rationale does not qualify as a basis for a health claim. The 1990 amendments require that a health claim be based on the totality of all available scientific evidence and significant agreement among experts qualified by training and experience to evaluate such evidence. Thus, the agency rejects the concept of "almost risk-free" or "no risk" as justification for a health claim because it is inconsistent with requirements of the 1990 amendments.

FDA disagrees with statements regarding the "low cost of such supplementation." Practical difficulties of providing folic acid supplements to all women before pregnancy, and particularly to women before their first pregnancies, are formidable and would be of substantial cost. These factors are important in this instance because there are no data demonstrating benefits to be derived from widespread supplementation of all women of child-bearing age.

The comments also included a number of references relating to effects of anticonvulsant drugs on folic acid status. These articles were included to demonstrate that certain subgroups in the population may require supplemental folic acid as a result of medications that they are taking.

Comments were received from two national professional organizations of nutritionists and public health nutrition directors. These comments advised a cautious approach to the use of health claims on foods and supplements with particular attention to avenues by which such claims might be abused or misinterpreted by the general public. The comments recommended that scientific agreement should be the cornerstone for the use of health claims, and that FDA consider data submitted in the context of meeting dietary requirements through intake of food. Some concern was expressed that the 1990 amendments allowed so many potential topics as candidates for possible health claims.

The government of Canada submitted information that it considered helpful in the context of increased harmonization of regulations or standards affecting trade in specific products. The Director General, Food Directorate, Health and Welfare Canada, wrote to the agency that health claims or messages regarding neural tube defects would likely result in a food product being classified as a drug in Canada by virtue of the definition of "drug" embodied in the Canadian Food and Drugs Act.

The official position of Canada on the relationship of diet and nutrients to disease and the metabolic effects of nutrients is stated in the volume *Nutrition Recommendations, the Report of the Scientific Review Committee—1990* (Ref. 17). In sections relating to folic acid, this report noted that there was particular interest in folate intake before conception and in early pregnancy in view of a reported possible relationship between folate and occurrence of neural tube defects. The report noted that intervention trials carried out in the United Kingdom (Refs. 18, 19, and 20) have been criticized, and that a large controlled trial on prepregnancy supplementation was in progress at the time of the report (Ref. 20). The report does not contain a recommendation for periconceptional supplementation with folic acid (Ref. 17).

II. Review of the Scientific Evidence

A. Federal Government Documents and Statements

In 1988, "The Surgeon General's Report on Nutrition and Health" (Ref. 21) considered the role of dietary factors in maternal health. This report reviewed the results of clinical trials in the United Kingdom in which folate and multivitamin supplements were used in attempts to reduce the risk of recurrence of neural tube defects in infants born to women who had previously had a pregnancy complicated by a neural tube defect. The Surgeon General's Report, citing extensive commentaries (Ref. 26), reported that these trials were poorly controlled for maternal diets and were methodologically flawed by poor compliance, questionable exclusion of eligible participants and recruiting bias (Ref. 21). The report did not make a recommendation with respect to folic acid supplementation before or during pregnancy (Ref. 21).

The U.S. Department of Agriculture and the Department of Health and Human Services, in "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 22), did not discuss any scientific evidence on a relationship between folic acid and neural tube defects. The target populations for these guidelines are healthy Americans and not those persons in the population with chronic diseases or those at high risk of specific diseases. In 1988, the CDC reviewed methodological concerns about case-control studies, and stated that the available evidence was insufficient to recommend multivitamin supplementation in the United States to prevent neural tube defects (Ref. 27).

Following the recent publication of the results of the Medical Research Council (United Kingdom) Vitamin Trial (Ref. 15), the CDC published guidelines, reprinted near the end of this preamble, recommending that a woman who has had a fetus or infant with a neural tube defect should consult with her physician at least 4 weeks before becoming pregnant and should take, under a physician's guidance, 4 mg folic acid per day through the first trimester of pregnancy (Ref. 16).

The CDC stated that these guidelines are not intended for women who have never had a neural tube defect-affected pregnancy, for relatives of women who have had an infant or fetus with a neural tube defect, for women who themselves have spina bifida, or for women who take the anticonvulsant drug valproic acid, a known cause of spina bifida (Ref. 16).

The National Institutes of Health's National Institute of Child Health and Human Development does not have a public policy on this issue (Ref. 28).

B. Other Documents and Statements

The NAS' 1989 report "Diet and Health" did not contain any general recommendation for periconceptional supplementation with folic acid (Ref. 23). No recommendations for periconceptional folic acid supplementation to reduce the risk of birth defects were made in the National Research Council's 1989 edition of "Recommended Dietary Allowances" (Ref. 24). In 1990, NAS reviewed the topic of periconceptional vitamin supplementation and neural tube defects in its report "Nutrition During Pregnancy" (Ref. 3). NAS reviewed studies of vitamin supplementation during the periconceptional period, case-

control and cohort studies of periconceptional multivitamin use, results of laboratory assessments of maternal vitamin status, and studies in animal model systems (Ref. 3). NAS found severe limitations in the available evidence including:

(1) Inconsistency of data associating multivitamin or folate use with protection against neural tube defect pregnancies; and

(2) Evidence that in animal model systems, deficiency of nutrients other than folic acid produced lesions similar to human neural tube defects (Ref. 3). NAS concluded that the scientific evidence derived from various types of human studies and from animal studies does not provide a sufficient basis for making broad recommendations concerning the periconceptional use of vitamins and minerals for the prevention of neural tube defects (Ref. 3).

LSRO of the Federation of American Societies for Experimental Biology also reviewed the scientific literature regarding folic acid and neural tube defects (Ref. 25). The LSRO report concluded that there is evidence that women who take folic acid or folic acid-containing vitamin supplements during the periconceptional period have a lower risk of having infants with neural tube defects. In reaching this conclusion, LSRO was frequently inconsistent in its review of the relevant human studies and in the conclusions drawn from the results of the studies. The report also failed to focus on the specific relationship of folic acid to neural tube defects and on the significant differences in risk of occurrence versus recurrence of neural tube defect-complicated pregnancies. LSRO also concluded that women who have given birth to an infant with a neural tube defect will have a lower risk of bearing another child with a similar defect in a subsequent pregnancy if they take a folic acid supplement during the periconceptional period.

Thus, the authors of Federal government documents and other authoritative reports (with the exception of the LSRO report noted above) from panels of experts who conducted indepth reviews of the effects of periconceptional use of vitamins and minerals found that the available evidence did not provide a basis on which to conclude that the periconceptional use of vitamins and minerals will reduce the risk of neural tube defects among women in the general United States population.

Several professional health organizations were also contacted to determine whether they have policies on periconceptional supplementation with folic acid and neural tube defects at this time. The American College of Obstetricians and Gynecologists does not provide any specific recommendations to their fellows on preconceptional folate supplementation (Ref. 29). The Spina Bifida Association of America does not have a policy respecting folic acid supplementation for reduction in risk of neural tube birth defects (Ref. 30). The Teratology Society has not issued a position paper on this topic (Ref. 31).

C. Review of the Scientific Literature

1. Evidence for an Association Between Intake of Folic Acid and Neural Tube Birth Defects

a. *Criteria used in evaluating studies.* Observational studies have suggested that environmental factors such as nutritional deficiencies of vitamins may be associated with the development of neural tube defects (Ref. 32). Such observations stimulated several epidemiological studies and clinical trials. This relationship has also been investigated in some animal studies.

FDA evaluated scientific evidence available from both human and animal studies against general criteria for good experimental design, execution, and analysis. The criteria that FDA used in evaluating human epidemiologic and clinical studies included (as appropriate):

(1) Reliability and accuracy of methods used in dietary assessment;

(2) Potential for misclassification of subjects with regard to dietary intake or supplement intake;

(3) Presence of recall bias and interviewer bias;

(4) Methods of determination of vitamin status;

(5) Methods of assignment of subjects to treatment or control groups for clinical trials;

(6) Choice of control subjects and representativeness of subjects;

(7) Control of confounding factors, such as demographic variables;

(8) Assessment of compliance with treatment regimens and degree of compliance.

The criteria used in evaluating studies in animals included:

(1) Appropriateness of the animal species, diets, and treatment regimens selected for study;

(2) Whether confounding factors were controlled;

(3) Whether the number of animals was large enough to produce reliable data;

(4) Whether duration of exposure and period of observation were appropriate; and

(5) Whether methods used in the measurement of responses were reliable and accurate.

FDA placed particular emphasis on those human studies that specifically addressed the issue of folic acid and neural tube defects. Those human studies that considered effects of combinations of nutrients were given less weight because they did not address the specific question of a relationship between folic acid and neural tube defects which was identified in the 1990 amendments.

Moreover, because the ability to generalize results obtained from studies of small populations to the much larger population of women in the United States is an important consideration, FDA also evaluated human studies with respect to whether the reported results could reasonably be extrapolated to the United States population. Additionally, because health claims will be directed to the general population of healthy adults, FDA did not evaluate studies describing special situations in which use of specific medications led to the development of vitamin deficiencies because these situations require medical supervision.

FDA evaluated the weaknesses and strengths of individual human studies (see "comments" in Tables 1 through 3). It then assessed the strength of the overall evidence (e.g., epidemiologic studies, assessment of maternal vitamin status, intervention trials, animal studies) taking into account the strength of the association, the consistency of findings, specificity of the association, evidence for a biological mechanism, and presence or absence of a dose-response relationship. FDA's conclusions are based upon the strength, consistency, and preponderance of data.

b. *Human studies.* Human studies on the association between folic acid use, multivitamin use, or maternal nutrition and neural tube defects are summarized in Tables 1 through 3. The major features of these studies (type and design of study, number of women studied, location of populations, nature and duration of treatment or supplement use, maternal diet assessments, and blood indices measured and the significant results) are included in these tables.

Human studies reported to date include four supplementation trials undertaken to reduce the recurrence rate of neural tube defects (Refs. 15, 18, 19, 33, and Table 1), and three casecontrol studies (Refs. 34, 35, 36, and Table 2) and one prospective cohort study (Ref. 37 and Table 2) undertaken to identify possible associations between multivitamin use or dietary folic acid intake and incidence of neural tube defects. There have also been a number of studies in which levels of various vitamins were measured in blood samples obtained from women during or following the periconceptional interval (Refs. 14, 38, 39, 40, and Table 3).

TABLE 1.—STUDIES OF EFFECTS OF PERICONCEPTIONAL FOLATE OR MULTIVITAMIN + MINERALS SUPPLEMENTATION ON RECURRENCE OF NEURAL TUBE DEFECTS

Reference study	Type	Location	Design	NTD defined [1,2]	Subjects	Treatment	Duration begin	End	Recurrences	Comments
Laurence et al., 1981 (Ref. 18).	Recurrence.	South Wales.	Placebo-controlled double-blind clinical trial.	Yes	60 treated 51 placebo	4 mg folic acid per day or placebo.	Cessation of contraception.	6 weeks into gestation.	3.3 percent among supplemented 7.8 percent among placebo.	Differences were not significant. Twenty-seven percent of treated group did not comply. Protective effect reached level of significance only when apparent noncompliers were removed. All 6 women who had NTD recurrences also had inadequate diets.
Smithells et al., 1983 (Ref. 19).	Recurrence.	United Kingdom (multicenter trial).	Prospective cohort.	Yes	454 supplemented. 519 unsupplement- ed.	Multivitamin + calcium + iron daily (folic acid in multivitamin = 0.36 mg per day) or unsupplemented.	Not less than 28 days before conception.	Approximately 6 weeks into gestation.	0.7 percent among fully supplemented 4.7 percent among unsupplemented.	Some NTD recurrences and some other major malformations occurred in fully supplemented subjects. Questionable exclusion of 4 fully supplemented subjects, 2 of whom subsequently had NTD infants, due to difficulty with precise timing.
Vergel et al., 1990 (Ref. 33).	Recurrence.	Cuba	Prospective cohort.	No	81 treated 20 partially supplemented. 114 unsupplemented.	5 mg folic acid per day or unsupplement- ed.	Not less than 1 month before conception for fully supplemented.	10th week of pregnancy.	0 percent among supplemented. 0 percent among partially supplemented. 3.5 percent among unsupplemented.	Differences were not statistically significant. Unsupplemented women were seen later in pregnancy than were supplemented women. Possible bias in recruitment of subjects. Folic acid status was measured in only part of the fully supplemented group and in none of the unsupplemented group.
Wald, 1991 (Ref. 15).	Recurrence.	International multicenter trial in 7 countries.	Randomized double-blind prevention trial.	Yes	1,817 women were recruited of whom 1,195 subsequently had informative pregnancies.	(A) Ca + Fe + 4 mg folic acid per day. (B) Ca + Fe + 4 mg folic acid per day + multivitamins. (C) Ca + Fe (D) Ca + Fe + multivitamins.	At randomization (unspecified time before conception).	End of first trimester (12 weeks of pregnancy).	Group (A), 2/298; (B), 4/295; (C), 13/300; (D), 8/302. Recurrence rate among women in groups (A + B) was 1.0 percent. Recurrence rate among women in groups (C + D) was 3.5 percent.	Significant protective effect of folic acid on recurrence of NTDs. There was no evidence that vitamins other than folic acid conferred the protective effect. Six NTDs recurred in women in groups A + B. Lack of compliance was unlikely as an explanation for these failures. There was no excess of non-NTD birth defects reported in any one group.

[1] NTD, neural tube defect, defined as anencephaly, encephalocele, spina bifida cystica (Laurence et al., 1981; Ref. 18) and as anencephaly, encephalocele, cranial meningocele, iniencephaly, myelocele, myelomeningocele and excluding isolated hydrocephalus and spina bifida occulta (Smithells et al., 1983; Ref. 19).
[2] NTD, neural tube defect, defined as anencephaly, spina bifida cystica and encephalocele by Wald, 1991 (Ref. 15). Multivitamin preparations contained vitamins A, D, B_1, B_2, B_6, C, and nicotinamide.

TABLE 2.—STUDIES OF ASSOCIATIONS BETWEEN PERICONCEPTIONAL MULTIVITAMIN USE AND/OR DIETARY FOLATE INTAKE AND OCCURRENCE OF NEURAL TUBE DEFECTS

Reference study	Type	Location	Design	NTD defined [1 2]	Birth years	Subjects	Reported use of supplements	Other	Duration of periconceptional use	Recall interval	Results	Comments
Mills et al., 1989 (Ref. 34).	Occurrence.	CA, IL	Case-control.	Yes	1985 to 1987.	571 NTD; 546 other defects-controls. 573 normal controls.	13 to 15 percent in each group.		30 days before 1st day of last menstrual period and continuing for 45 days.	Less than 5 months.	Mothers of infants/fetuses with NTD were no less likely to have taken multivitamins or folate in periconceptional interval than were women in the control groups. Use of multivitamin supplements not associated with reduction in frequency of NTD.	Cases, controls matched for age, race, education, family income, gavidity. Attempts made to minimize recall bias. Information on multivitamin use obtained after abnormal birth was identified. Not all cases could be identified and interviewed.
Bower and Stanley, 1989 (Ref. 35).	Occurrence.	Western Australia.	Case-control.	Yes	1982 to 1984.	77 NTD; 77 other defects-controls.	15 to 21 percent in each group.	Food frequency questionnaire covering 12 month interval.	3 months before to 9 months after last menstrual period.	Not stated (possibly at least 1 year).	Increasing intake of folate (assessed by dietary intake and folate supplementation) in 1st 6 weeks of pregnancy was protective against occurrence of isolated neural tube defects.	No evidence for a protective effect of conjugated folate. Protective effect also observed for dietary fiber, calcium, vitamin C, and carotene. Measures of post-partum dietary folate status showed no association with occurrence of NTD births.
Mulinare et al., 1988 (Ref. 36).	Occurrence.	Metropolitan Atlanta.	Case-control (Atlanta Birth Defects Case-control Study).	Yes	1968 to 1980.	349 NTD; 2,829 controls.	Case mothers, 7 percent. Control mothers, 15 percent.	Maternal diet not assessed.	3 months prior to pregnancy through 1st trimester.	2 to 16 years.	Estimated risk of having NTD-affected infant was significantly lower for multivitamin users (approximately) 2.5-fold protective effect). Protective effect less pronounced when cases were compared to abnormal controls.	Compositions of multivitamin preparations not known. Users were different from nonusers in some demographic, health-related, lifestyle characteristics. Apparent protective effect was significant for whites but not for other races. Maternal nutrition during periconceptional period not known. No major differences seen for early and late postconceptional use.
Milunsky et al., 1989 (Ref. 37).	Occurrence.	New England (86 percent); other (14 percent).	Prospective cohort-women who underwent screening at about week 16 of pregnancy.	Yes	1984 to 1987.	49 NTD 22,727 controls.	31.9 percent of entire cohort used multivitamins during periconceptional interval.	Maternal diet assessed.	3 months prior to pregnancy through 1st trimester.	Several months.	Prevalence of NTD was significantly lower for women who used multivitamins with folate during periconceptional interval. Among nonusers, prevalence rates were lower for those whose diets provided >100 micrograms (μg) folate per day.	A substantial majority of the preparations contained vitamins A, C, D, and/or E. The possibility cannot be ruled out that vitamins A, C, D, and E alone or in combination(s) with folic acid were protective. Users were defined as taking at least one multivitamin per week but the majority took preparations more frequently.

[1] NTD, neural tube defect, defined as anencephaly, meningocele, encephalocele, rachischisis, iniencephaly, lipomeningocele (Mills et al., 1989; Ref. 34). Isolated hydrocephalus, hydranencephaly, dermal sinus, and spina bifida occulta were excluded from cases, and oral cleft, deformation, cosmetic defects and hydrocephalus were excluded from defect controls by Mills et al. (Ref. 34). NTDs were defined as anencephaly, spina bifida and encephalocele by Bower and Stanley (Ref. 35).

[2] NTD, neural tube defect, defined as anencephaly and spina bifida (Mulinare et al., 1988; Ref. 36) and as any combination of spina bifida, anencephaly, or encephalocele alone or in combination with other defects (Milunsky et al. 1989; Ref. 37).

TABLE 3.—MEASUREMENTS OF MATERNAL VITAMIN STATUS AS RELATED TO CENTRAL NERVOUS SYSTEM DEFECT- OR NEURAL TUBE DEFECT-PREGNANCIES

Reference	Location	Subjects and samples	Major findings
Smithells et al., 1976 (Ref. 14).	Leeds, UK	Approximately 900 women. Blood samples were obtained not more than 13 weeks after the start of the last menstrual period.	Mean values for all vitamin levels determined were most satisfactory for women in the highest social classes. Values for erythrocyte and white blood cell ascorbate were significantly lower in women who subsequently had an infant with a CNS [1] defect than in control women. Mean values for serum folate and saturation index for riboflavin were also poorer among women who had an infant with a CNS defect than mean values for all social classes.
Molloy et al., 1985 (Ref. 48).	Dublin, UK	32 NTD [2] cases, 395 controls. Blood samples obtained from 8 to 32 weeks of gestation.	Maternal serum folate and vitamin B_{12} were not significantly different between cases and controls. An hypothesized association between vitamin B_{12} deficiency and anencephaly was not confirmed in this study.
Yates et al., 1987 (Ref. 49).	Scotland, UK	20 women with history of 2 or more NTDs, 20 matched controls. Blood samples obtained after birth of index case.	Erythrocyte folate was significantly lower in women who had 2 or more NTDs than in controls. No differences in serum folate, vitamin B_{12}, or other serum vitamin measurements (plasma or white blood cell vitamin C, vitamin A, thiamine, riboflavin, pyridoxine, vitamin E) between cases and controls. Distributions of dietary folate intakes were not significantly different among groups.
Mills et al., 1991 (Ref. 50).	Finland	89 NTD cases, 172 controls. Over 85 percent of blood samples obtained within 8 weeks of neural tube closure.	No significant differences between cases and controls in serum levels of folate, vitamin B_{12}, or retinol.

[1] CNS, central nervous system. Specific abnormalities of CNS not defined by Smithells et al. (Ref. 14);
[2] NTD, neural tube defect. Cases of anencephaly, spina bifida, and encephalocele reported by Molloy et al. (Ref. 48); not defined by Yates et al. (Ref. 49) or Mills et al. (Ref. 50).

i. *Recurrence trials.* Of the four intervention trials with women who were at high risk of neural tube defect-affected pregnancies because of a history of such pregnancies (that is, women at high risk of a recurrence) (Refs. 15, 18, 19, 33, and Table 1), three trials involved daily supplementation with 4 or 5 mg of folic acid alone during the periconceptional interval (Refs. 15, 18, and 33). Two of these trials did not find a statistically significant reduction in neural tube defects. In one of these studies (Ref. 18), 27 percent of the folic acid-treated group did not comply with the treatment regimen. A statistically significant difference between treatment and control groups was found only when apparent noncompliers (identified on the basis of arbitrarily determined serum folate values) were discounted (Ref. 18).

A second intervention study involving daily supplementation with 5 mg folic acid alone was a prospective cohort

study carried out in Cuba (Ref. 33 and Table 1). Although this study showed a decreased risk of recurrence of neural tube defect-affected infants in the supplemented women, the reduction was not statistically significant. Furthermore, a bias in recruitment may have occurred because unsupplemented women in this study were seen later in pregnancy than were supplemented women. The characteristics of a "partially supplemented" group with respect to folic acid treatment were not defined (Ref. 33). Folic acid status was measured in only some women in the fully supplemented group and in none of the women in the unsupplemented group.

An intervention trial that did find a statistically significant difference in the recurrence rate of neural tube defects between supplemented and unsupplemented women (Ref. 19) measured the use of a multivitamin preparation containing folic acid, vitamins A and D, thiamine, riboflavin, pyridoxine, nicotinamide, and ascorbic acid plus minerals (ferrous sulfate and calcium phosphate) rather than folic acid alone. Daily folic acid intake from the multivitamin plus minerals preparation was 360 mg (0.36 mg). The design of this study was inadequate to test the hypothesis that folic acid supplementation would reduce the rate of recurrence of neural tube defects in women who had previously given birth to infants with neural tube defects because intakes of other nutrients in addition to folic acid were also increased in the supplemented women.

The results of a major randomized double-blind prevention trial to determine whether supplementation with folic acid alone or in combination with seven other vitamins could reduce the risk of neural tube defects in women at high risk because of a previous affected pregnancy were reported in July 1991 (Ref. 15). This international study involved women in 33 centers in the United Kingdom, Hungary, Israel, Australia, Canada, the USSR, and France. The study began in 1983 under the supervision of the Medical Research Council, United Kingdom, and was stopped in 1991, because of findings of a significant protective effect of folic acid supplementation against recurrences of neural tube defects in infants of women at high risk of this complication.

The major features of this study are included in Table 1. Women with epilepsy were excluded to avoid adverse effects of high folic acid supplementation on their treatment. A total of 1,817 women at high recurrence risk of neural tube defect pregnancies were randomized to the four treatment groups. Women remained in the trial in the same randomization groups until they had a pregnancy in which the fetus could be classified as having or not having a neural tube defect. Such outcomes were defined as "informative" pregnancies. One thousand one hundred ninety-five women of the 1,817 women randomized (66 percent) had such an informative pregnancy. Two hundred eighty-seven of these informative pregnancies (24 percent) were reported from Glasgow, Scotland, and 201 (17 percent) were reported from Budapest, Hungary, both areas of known high prevalence rates of neural tube defects.

All fetuses and infants were examined. Independent corroboration of all reported neural tube defects was obtained with a necropsy report or a description of the lesions for independent review without knowledge of the allocated group. Final results were based upon the results of all informative pregnancies. The characteristics of the 622 women who did not have informative pregnancies (34 percent of the number randomized) have not as yet been reported (Ref. 15).

Information was obtained for all abnormalities other than neural tube defects in all informative pregnancies. This information provided the basis for a determination that supplementation with folic acid specifically affected rates of recurrence of neural tube defects. The variety of other birth defects that occurred were evenly distributed across all randomization groups. The results of this carefully performed study showed that folic acid at 4 mg per day, with or without other vitamins, significantly reduced the risk of recurrences of neural tube defects in women at high risk of this complication. Six neural tube defects recurred in women in the folic acid-supplemented groups, however, showing that factors other than folic acid status are important in the etiology of neural tube birth defects. The trial had sufficient power to demonstrate efficacy of the treatment for women at high risk of recurrence but did not have sufficient power to answer questions of safety for these women.

ii. *Occurrence studies.* Two case-control studies and one prospective cohort study (Refs. 35, 36, 37, and Table 2) found associations between reduced rates of neural tube defects and use of multivitamin supplements in the periconceptional interval. In one case-control study of multivitamin use in women in the Atlanta area (Ref. 36), the compositions of multivitamin preparations used during the periconceptional interval could not be ascertained because of lengthy recall intervals. In this study, supplement use was based upon recall of events occurring 2 to 16 years before the interview (Ref. 36).

A prospective study of women in the Boston area found that use of a multivitamin supplement that contained folic acid during the first 6 weeks of pregnancy was associated with a reduction in the incidence of neural tube defects, and that no effects were observed if use of the folic acid-containing supplement began after the 6th week of pregnancy (Ref. 37). Estimation of when the use of supplements began during pregnancy depended upon self-reported pregnancy duration, which was in practice based on the date of the woman's last menstrual period (Ref. 37). The majority of the preparations reported as used in this study (Ref. 37) contained vitamins A, C, D, or E in addition to folic acid, however. Therefore, the protective agent cannot be identified. In this same study, dietary folic acid intake was calculated by means of the diet portion of the study questionnaire only for those women who were not taking a multivitamin supplement. Nonusers of multivitamin supplements who had dietary folate intakes greater then 100 μg per day had a lower incidence of neural tube defects than did nonusers whose diets provided less than 100 μg of folic acid per day (Ref. 37). Estimated intakes of nutrients other than folic acid were not reported (Ref. 37).

In a case-control study carried out in western Australia (Ref. 35 and Table 2), apparent protective effects were found for folic acid. However, this study found that dietary fiber, calcium, vitamin C, and carotene were also apparently protective against the occurrence of neural tube defects. This study found that free folate appeared to provide a stronger protective effect against occurrence of isolated neural tube defects than did total folate. Such an observation, if confirmed, may imply the existence within subgroups in the Australian population of a defect (possibly genetic) in intestinal conjugase activity (the enzyme activity that breaks down food-derived folylpolyglutamates) that would be expected to reduce the availability of food-derived folate. Alternately, such a result may represent problems in estimating folate contents of diets from food composition tables.

An additional case-control study involving women in California and Illinois did not find a protective effect on the incidence of neural tube defects from the use of folate-containing multivitamin preparations during the

periconceptional interval (Ref. 34 and Table 2). Supplement usage among women who had a neural tube defect-complicated pregnancy was compared to usage of supplements among women who had normal infants as well as to supplement usage among women who had infants born with abnormalities other than neural tube defects. Use of multivitamin supplements was reported to be the same among women in all three groups, and no protective effect was identified (Ref. 34).

Commentaries on the four studies cited above have been numerous (Refs. 38–46) and include considerations of the role of health-conscious behavior in reduction in risk of neural tube defects (Ref. 38), significance of biases in recall (Ref. 39), problems with case-identification methods (Ref. 40), and differences in prevalence rates in the study areas (Ref. 44). Researchers in the United Kingdom observed, in studies with women at high risk for neural tube defect recurrences, that effects of vitamin therapy are more marked in high-prevalence areas than in low-prevalence areas (Ref. 47). It is important to note that among the four epidemiologic studies cited above, the three studies that showed a positive effect of folic acid or multivitamin supplementation involved populations of higher prevalence of neural tube defects (Boston, 3.5 neural tube defects per 1,000 births (Ref. 37); Atlanta, 1.8 per 1,000 (Ref. 36); and Perth, Australia, 1.5 per 1,000 (Ref. 35)) than did the single study that did not reveal such an effect (California and Illinois, 0.91 neural tube defects per 1,000 births (Ref. 34)). The prevalence factor may be highly important when a multifactorial condition is under investigation, and when prevention or reduction in risk is attempted through manipulation of the environmental (for example, nutritional) component (Ref. 41). The environmental contribution to the total etiology is thought to be greater in areas of higher prevalence. Consequently, in low prevalence areas, a higher percent is attributable to genetic factors and less is attributable to environmental factors (Ref. 41).

None of the epidemiologic studies was able to identify any one factor that was specifically related to reduction in risk of neural tube defects. Maternal dietary counseling and maternal dietary improvement appeared to be as effective a measure as supplementation in decreasing the risk of having an infant affected with a neural tube defect (Ref. 60). Furthermore, all of these epidemiologic studies suffered from biases, including problems with differences in length of recall (Ref. 36), differences between cases and controls relative to socioeconomic status and lifestyle characteristics (Ref. 36), nonrepresentativeness of subjects (Ref. 37), inability to identify and interview all cases (Ref. 34), and possible inaccuracies in determining dietary folate content from food composition tables (Ref. 35). In summary, the results of these occurrence studies do not provide a basis on which to find an association between ingestion of folic acid and reduction in risk for neural tube defects.

iii. *Measurements of maternal vitamin status.* Clinical measures of maternal vitamin status (including folate) also provide no evidence for a consistent association between folic acid intake and neural tube defects. One study (Ref. 14, Table 3) showed that mean blood values for all vitamins determined were most satisfactory for women in the highest social classes. Additionally, mean values for several vitamins were poorer among women who had an infant with a CNS defect than mean values for all social classes (Ref. 14).

Another study (Ref. 49 and Table 3) reported that erythrocyte folate values were significantly lower among women who had repeated neural tube defect pregnancies than among controls. However, dietary intakes of folate among the groups of neural tube defect-affected mothers and control mothers were not significantly different and did not correlate with pregnancy outcome. Thus, an association between risk of having offspring with neural tube defects and decreased erythrocyte folate levels could not be attributed to lower dietary folate intake by the mothers of neural tube defect-affected infants (Ref. 49). Another study did not find differences in parameters of folate status between mothers of neural tube defect infants and controls (Ref. 48).

A report of maternal serum vitamin measurements in a population-based study of Finnish women who gave birth to infants with neural tube defects (Ref. 50 and Table 3) found no significant difference in serum folate levels between women who gave birth to a neural tube defect-affected infant and control women (Ref. 50).

c. *Animal studies.* Studies with animal model systems are one of several lines of investigation that are used to establish associations between deficiencies or excesses of various nutrients and birth defects. Such studies have provided some support for the hypothesis that nutrient deficiencies may be one factor in the etiology of neural tube defects (Ref. 51). Deficiencies of nutrients such as vitamin B_{12}, vitamin B_6, pantothenic acid, and vitamin E have been reported to cause neural tube defects in some species (Ref. 1).

In rats, maternal folic acid deficiency alone does not produce neural tube defect-affected embryos in a reproducible manner (Ref. 26). However, rats fed folate-deficient diets in conjunction with antifolates during pregnancy do produce embryos with multiple congenital abnormalities (Ref. 52). A high spontaneous rate of neural tube defects that closely resemble those seen in humans occurs in the curly-tail mouse. These defects appear to be related to a recessive gene whose expression is modified by the rest of the genome (the complete set of hereditary factors contained in the chromosomes) (Ref. 53). Excess vitamin A administered on the 8th day of gestation increased the incidence of neural tube defects in this mouse in a dose-dependent manner. A variety of compounds including folic acid, folinic acid, methotrexate, vitamin B_{12}, and vitamin E did not significantly affect the incidence of the defect in this model system (Ref. 54).

Neural tube defects in the golden hamster model can be induced by maternal hyperthermia or ethanol following exposures early in gestation. Folate supplementation begun before such treatments does not prevent the alcohol or heat-induced neural tube defects (Ref. 55).

Neural tube defects can be induced by administration of the anticonvulsant drug valproic acid to mice on the 8th day of gestation (Ref. 56). The administration of 5-formyltetrahydrofolate, an active metabolite of folic acid, significantly reduces the rates of these defects. The authors of this study suggested that this model system may be appropriate for studies of protective effects of folates on occurrence of neural tube defects (Ref. 56). Results of mechanistic studies directed toward identifying valproic acid-induced disturbances in folate metabolism have been reported (Ref. 57).

The results of animal studies do not provide evidence for a consistent association between folic acid nutriture and neural tube defects but show that disturbed folate metabolism may be one factor in the complex etiology of neural tube defects.

2. Other Relevant Information

a. *Evidence for efficacy of Dericonceptional supplementation of women at high risk of neural tube defect pregnancies with less than 4 mg folic acid per day.* The daily intake of folic

acid that significantly reduced the risk of recurrences of neural tube defects in high-risk women in the United Kingdom trial was 4 mg and was provided as a supplement (Ref. 15). A daily folic acid intake of 4 mg cannot be attained from usual diets, even when such diets are high in folate-rich foods such as dark green leafy vegetables and liver. Additionally, food additive regulations in the United States do not permit addition of folic acid at high levels to foods or supplements (21 CFR 172.345). Therefore, the agency examined the results of all available human studies to determine whether such studies provide data showing that significant reductions in risk of neural tube defects occurred with intakes of folic acid below 4 mg per day and within the range of folic acid intake attainable in usual diets.

The agency examined the results of both intervention and epidemiologic studies. Only one of four human intervention trials involved supplementation with less than 4 or 5 mg folic acid per day (Ref. 19). A nonrandomized intervention trial carried out in the United Kingdom found a significant difference in the recurrence rate of neural tube defects between women given a multivitamin plus minerals supplement and those who were not supplemented. The multivitamin plus minerals supplement given to some of the women provided folic acid at 360 μg per day. No true control group was included in this trial. Supplemented women were recruited well before conception while unsupplemented women were already pregnant before referral to the study. The design of this study was inadequate to test the hypothesis that folic acid supplementation would reduce the risk of recurrence of neural tube defects in women who had previously given birth to infants with such defects because the supplement used contained a number of vitamins and two minerals in addition to folic acid.

In this study (Ref. 19), attempts were made to examine all infants of fully-supplemented mothers to determine whether vitamin supplementation might harm the embryo or fetus. Results of such examinations were reported for only part of the fully-supplemented group but not for partially-supplemented or unsupplemented groups (Ref. 19). Thus, no comparison of effects between supplemented and unsupplemented groups was possible. The proportions of spontaneous abortions examined in fully-supplemented and unsupplemented women were 61 percent in the first cohort and 32 percent in the second cohort reported (Ref. 19). In contrast, results of all informative pregnancies were reported in the recently published Medical Research Council trial (Ref. 15), leading to virtually complete ascertainment of treatment effects. Thus, efficacy of a dose of folic acid of 360 μg cannot be determined from Ref. 19.

Examination of epidemiologic studies for information pertaining to efficacy of lower doses of folic acid did not provide definitive results. For example, in one study that reported that use of multivitamins containing folic acid reduced the risk of having a neural tube defect-affected infant, the compositions of the multivitamin preparations containing folic acid were not known because of long recall intervals (2 to 16 years) (Ref. 36). In another study that reported that the prevalence of neural tube defects was significantly lower for women who used multivitamins during the periconceptional interval than for women who did not, the multivitamin preparations contained folic acid at levels of 100 to 1,000 μg (Ref. 37). A substantial majority of the preparations also contained vitamins A, C, D, or E. In this study, an efficacious dose of folic acid could not be identified and the possibility could not be ruled out that other vitamins alone or in combination with folic acid were protective.

These studies (Refs. 19, 36, and 37) do not provide sufficient evidence that doses of folic acid lower than 4 mg per day provide significant reductions in risk of recurrence of neural tube defect-affected pregnancies. Thus, evidence of efficacy of doses of folic acid lower than 4 mg per day is lacking. The agency tentatively concludes, based on the currently available evidence, that the amount of folic acid supplementation needed for reduction in risk of neural tube defects in women at high risk of this complication is the level used in the Medical Research Council vitamin study (i.e., 4 mg per day) (Ref. 15).

b. *Significance of studies with anticonvulsant drugs.* FDA recognizes that there is a considerable literature on possible roles of drug-induced nutritional deficiencies in causation of birth defects. Anticonvulsant drugs taken during pregnancy are among a number of factors implicated in the increased risk of congenital malformations including neural tube defects reported in children of women with epilepsy. Abnormalities in vitamin status for biotin, folate, 25-hydroxy-vitamin D, and vitamin A have been reported in anticonvulsant-treated epileptic women. FDA believes that serious medical conditions such as epilepsy should be handled under medical supervision, and that nutritional guidance for anticonvulsant-treated pregnant women or anticonvulsant-treated women planning pregnancy should be provided by trained medical personnel.

c. *Safety considerations.* In "Nutrition During Pregnancy," NAS reviewed the safety of folic acid intake during pregnancy (Ref. 3). It found that the safety of large doses of folic acid during pregnancy had not been systematically evaluated, and that the effects of large maternal doses of folate on the developing fetus are not known (Ref. 3). NAS cited studies (Refs. 58 and 59) that suggested that large doses of folic acid may inhibit the absorption of other nutrients by competitive interaction. Large doses of folic acid may also make it more difficult to diagnose the onset of, or a relapse of, pernicious anemia (Ref. 3). This fact is important because pernicious anemia may occur in pregnant women with impaired vitamin B_{12} absorption caused by lack of intrinsic factor, gastrectomy, or small intestinal disorders that affect the ileum.

The National Research Council, in its 1989 edition of the "Recommended Dietary Allowances" (Ref. 24), also reviewed effects of excessive intakes and toxicity of folic acid in humans and animals. The National Research Council (Ref. 24) concluded that without evidence of benefit, and with some potential for toxicity, excessive intakes of supplemental folic acid are not recommended.

The Medical Research Council vitamin study (Ref. 15) examined effects of supplementation with 4 mg folic acid per day in fetuses and mothers. The number of reported congenital abnormalities other than neural tube defects was similar in all four groups. The mean number of women reporting various medical disorders during the study was also similar in all groups. Thus, supplementation of women at high risk of neural tube defect pregnancies with 4 mg folic acid per day during the periconceptional interval was not associated with adverse effects, but the ability of the study to identify such effects was limited by the size of the groups.

The design of the United Kingdom trial was sufficient to demonstrate efficacy of folic acid supplementation in high-risk women (Ref. 15). It did not, however, have sufficient power to evaluate safety for these high-risk women or for broader public health purposes. The study did not examine the benefit or risk of folate supplementation among low-risk women (those who are not at risk of recurrence of a neural tube

defect-affected pregnancy). Unanswered questions of major concern include those of efficacy and safety of similar intervention in the much larger population of women in the United States at considerably lower risk of occurrence of neural tube defect-complicated pregnancies. There are currently no data demonstrating safety of long-term supplementation of women of child-bearing age with folic acid at the dose used in the United Kingdom Medical Research Council vitamin trial.

3. Conclusions

Until the July 1991 publication of the Medical Research Council's report (Ref. 15), the human studies on the hypothesized association between ingestion of folic acid and reduction in risk of neural tube defects were limited in design and were inconsistent in their findings. Human intervention trials using folic acid would be expected to provide the strongest evidence for efficacy of folic acid supplementation if such trials demonstrated significant reductions in the risk of neural tube defects following folic acid supplementation. Two early trials examining periconceptional supplementation with 4 or 5 mg folic acid alone in women at high risk of neural tube defect recurrences produced nonsignificant results (Refs. 18 and 33). A single nonrandomized intervention study that did find a statistically significant reduction in neural tube defects in women at high recurrence risk of this complication measured usage of a multivitamin plus minerals supplement in addition to folic acid rather than folic acid alone (Ref. 19) and thus, could not demonstrate an independent effect of folic acid supplementation.

The Medical Research Council's randomized double-blind multi-center trial (Ref. 15) clearly demonstrated a significant reduction in recurrence rate of neural tube defects in women supplemented kingdom with 4 mg folic acid per day. No protective effects of vitamins other than folic acid were observed (Ref. 15), and no data were provided to demonstrate the efficacy of doses lower than 4 mg per day. This study established a specific role for folic acid in reduction in risk of recurrence for a significant proportion of neural tube birth defects in women at high risk for this complication because of a history of neural tube defect pregnancies and has provided useful information on an important medical question (Ref. 59).

The four human intervention trials reported to date have been recurrence trials carried out in women in the United Kingdom, Hungary, Israel, Australia, Canada, the USSR, France, and Cuba in women with known high risks of neural tube defect-complicated pregnancies (Refs. 15, 18, 19, and 33). The high incidence of neural tube defects among women in Scotland and in Ireland has made these areas a focus of interest for studies of neural tube defects for many years. Studies in such high incidence areas as those mentioned above enhance the ability to examine cause and effect relationships.

Determination of whether the findings of the Medical Research Council trial with respect to supplementation of women at high risk of recurrent neural tube defect-complicated pregnancies can be extrapolated to other populations at much lower risk is problematic. As noted above, the Medical Research Council trial demonstrated efficacy of folic acid supplementation only in women at known high risk of recurrence of neural tube defect-complicated pregnancies because of a prior history of such a pregnancy. It did not examine effects of such supplementation in women at much lower risk of a first occurrence of a neural tube defect. It is important to note that the recurrence rate of neural tube defects in folate-supplemented women in the Medical Research Council trial was 1 percent (Ref. 15). This rate is at least 10 times higher than the rate of occurrence of neural tube birth defects in the general United States population and emphasizes the important distinction that must be made between risk of occurrence and risk of recurrence of neural tube defects.

The ability to project efficacy of folic acid intervention under U.S. dietary and lifestyle conditions is limited by the fact that none of the four intervention trials were carried out in the United States, an area of very low risk relative to the other areas studied. Moreover, the results of these intervention studies, which examined only recurrences of neural tube defects in areas of high prevalence, may not be generalizable to the considerably larger population of women in the United States who are at a much lower risk for a first occurrence of a neural tube defect-affected pregnancy.

The ability to generalize results obtained from studies of high-risk populations to the much larger population of "all women of child-bearing age" who would be targeted by specific health claims is an important concern. There is a question as to whether data obtained from recurrence trials abroad (Refs. 15, 18, 19, and 33) can be extrapolated to women in the United States who have never had a neural tube defect pregnancy.

Considerations of the ability to generalize results also pertain to several epidemiologic studies carried out in the United States. For example, the authors of a large prospective cohort study of the occurrence of neural tube defects recruited women who were receiving prenatal care and had a maternal alphafetoprotein screen or an amniocentesis (Ref. 37). Such women are not representative of pregnant women in the general population. The results of another study found that the apparent protective effects of periconceptional multivitamin use were statistically significant for white women but not for women of other races (Ref. 36). Racial differences in risks for neural tube defects are well-recognized (Ref. 2).

In general, women included in these studies on neural tube defects may not be representative of an entire population of women at lower risk because those who take or are willing to take supplements may have other characteristics that by themselves decrease the risk of having an infant with a neural tube defect. For example women who have had a neural tube defect-complicated pregnancy and who are seeking to avoid a recurrence may be more willing to seek medical advice before conception, or to take a supplement during the periconceptional interval, than women who have never had a birth defect-affected pregnancy. The fact that the sizes of the populations studied and their risks for neural tube defect pregnancies differed widely further complicates a determination as to whether such results can be generalized to a potential target population including all women in the United States of child-bearing age.

To date, a relationship between inadequate dietary intake of folic acid and increased risk of neural tube defects has not been established. The Medical Research Council's multi-center trial did establish that periconceptional supplementation of women at high risk of neural tube defect pregnancies with 4 mg folic acid per day led to significant reductions in recurrences of neural tube defects (Ref. 15). The trial did not, however, demonstrate a total elimination of recurrent neural tube defect complications in the high-risk women. In the Medical Research Council's study, 6 of 27 reported neural tube defects (22 percent) recurred in women in groups receiving folic acid supplementation. Since serum folate levels in these women were not unusually low for supplemented women, lack of compliance with the supplementation or failure to absorb folic acid were unlikely explanations for

these recurrences (Ref. 15). Thus, a significant fraction of neural tube defect recurrences were apparently resistant to folic acid supplementation. The genetic or metabolic factors underlying these defects are not understood. Such observations emphasize the heterogeneous (or multifactorial) etiology of neural tube defects.

The daily intake of folic acid that significantly reduced the risk of recurrences of neural tube defects in high-risk women in the United Kingdom trial was 4 mg and was provided as a supplement (Ref. 15). As stated above, daily folic acid intake of 4 mg cannot be attained from usual diets, even when such diets are high in folate-rich foods such as dark green leafy vegetables and liver. Additionally, the amount of folic acid needed for efficacy in reducing the rates of recurrent neural tube defects in women at high risk exceeds the amount that can safely be added to foods under current food additive regulations (21 CFR 172.345). Therefore, the agency examined the results of all available human studies to determine whether such studies provide data showing that significant reductions in risk of recurrent neural tube defects occurred with intakes of folic acid below 4 mg per day and within the range of folic acid intake attainable in usual diets.

Only one of four human intervention trials involved supplementation with less than 4 or 5 mg folic acid per day (Ref. 19). This nonrandomized intervention trial measured use of a multivitamin plus minerals supplement which provided folic acid at 360 μg per day. No true control group was included in this trial. Thus, the design of the study was inadequate to test the hypothesis that folic acid supplementation would reduce the risk of recurrence of neural tube defects in women who had previously given birth to infants with neural tube defects because nutrients other than folic acid were included in the supplements (Ref. 19). Moreover, examination of epidemiologic studies for information pertaining to efficacy of doses of folic acid lower than 4 mg per day did not provide definitive results because the compositions of multivitamin preparations used could not be determined (Ref. 36) or because folic acid content of preparations varied over a wide range (Ref. 37).

Thus, because scientific evidence of efficacy of doses of folic acid less than 4 mg per day in reducing rates of neural tube defect recurrences is lacking, the agency tentatively concludes that the amount of folic acid supplementation needed for reduction in risk of recurrent neural tube defects in women at high risk of such recurrences is 4 mg per day (i.e., that level which produced significant findings in the United Kingdom trial (Ref. 15)).

The agency also considered whether claims relating intake of multivitamins including folic acid to reduction in risk of neural tube defects would meet the standard set forth in the 1990 amendments. The agency did not broaden the scope of its considerations to include, for example, multivitamins containing folic acid and other combinations of nutrients and folic acid, because the 1990 amendments clearly identified folic acid and neural tube defects as one of 10 specific topic areas for which the validity of health claims was to be determined. Furthermore, the studies that found an association between use of multivitamin supplements and reduction in risk of neural tube defects did not specify the composition of such supplements (i.e., neither the identity of the vitamins present nor their concentrations were known). Most importantly, the United Kingdom Medical Research Council trial (Ref. 15) demonstrated that vitamins other than folic acid provided no protective effect against recurrence risk of neural tube defect pregnancies (Ref. 15).

III. Tentative Decision to Deny a Health Claim Relating Ingestion of Folic Acid to Reduced Risk of Neural Tube Birth Defects

FDA is proposing not to authorize the use on the labels and labeling of foods, including dietary supplements, of health claims relating to the association between ingestion of folic acid and reduction in risk of neural tube birth defects. Health claims on foods are intended to provide consumers in the general population with information relative to relationships between usual intakes of nutrients and reductions in risk of specific diseases (see companion document "Food Labeling: General Requirements for Health Claims for Food: Proposed Rule," published elsewhere in this issue of the **Federal Register**). The amount of folic acid needed for reduction in risk of neural tube birth defects in women at high risk of this condition is significantly in excess of usual intakes and exceeds amounts permitted under current food additive regulations. FDA has determined that products that provide the necessary amount of folic acid are drugs. In addition, there is no scientific evidence that periconceptional supplementation of women of childbearing age with doses of folic acid lower than 4 mg per day will significantly reduce the risk of neural tube birth defects. For all these reasons, FDA has tentatively determined that claims on foods, including dietary supplements, relating to folic acid and reduction in risk of neural tube birth defects are not justified.

The agency recognizes the significance of the recently published Medical Research Council Vitamin trial and the importance of its findings for women at high risk of recurrence of neural tube defect-affected pregnancies. The results of this carefully performed trial demonstrated that significant reductions in risk of recurrent neural tube defects could be achieved by supplementation of women at high risk with supraphysiologic levels of folic acid. Such therapeutic use of folic acid as a drug, however, permits a risk-benefit consideration that is inappropriate for a food. Recent statements by the CDC provide guidelines for use of folic acid by those women who are planning a pregnancy and who are at high risk of such a complication (Ref. 16). Because of the importance of this guidance, FDA is reprinting significant portions of the CDC recommendations:

1. Women who have had a pregnancy resulting in an infant or fetus with a neural tube defect should be counseled about the increased risk in subsequent pregnancies and should be advised that folic acid supplementation may substantially reduce the risk for neural tube defects in subsequent pregnancies.

2. Women who have had a pregnancy resulting in an infant or fetus with a neural tube defect should be advised to consult their physician as soon as they plan a pregnancy. Unless contraindicated, they should be advised to take 4 mg per day of folic acid starting at the time they plan to become pregnant. Women should take the supplement from at least 4 weeks before conception through the first 3 months of pregnancy.

3. The 4 mg daily dose should be taken only under a physician's supervision. Tablets containing 1 mg folic acid are available as a prescription item. The folic acid dose should be obtained from pills containing only folic acid. Multivitamin (over-the-counter and prescription) preparations containing folic acid should not be used to attain the 4 mg dose because harmful levels of vitamins A and D could also be taken. Prescribing physicians should be aware of the potential for high doses of folic acid to complicate the diagnosis of vitamin B_{12} deficiency. Anemia resulting from vitamin B_{12} deficiency may be prevented with high doses of folic acid; however, the neurologic damage that can result from vitamin B_{12} deficiency could continue.

4. These recommendations are provided only for women who previously have given birth to an infant or had a fetus with a neural tube defect; they are not intended for (1) women who have never given birth to an infant or had a fetus with a neural tube

defect, (2) relatives of women who have had an infant or fetus with a neural tube defect, (3) women who themselves have spina bifida, or (4) women who take the anticonvulsant valproic acid—a known cause of spina bifida. (Ref. 16).

The standard proposed in "Food Labeling: General Requirements for Health Claims for Food: Proposed Rule" (published elsewhere in this issue of the Federal Register) requires that a health claim be supported by the publicly available scientific evidence, and that there be significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, regarding such support. Clearly, on the issue of use of folic acid supplementation to reduce the risk of neural tube defects, there is no such evidence at levels of folic acid that can be safely added to foods (including dietary supplements), and thus there is no basis for agreement as to the appropriateness of using folic acid-containing dietary supplements to attempt to reduce the risk of neural tube defects among women in the general United States population. Thus, the agency is proposing not to authorize the use on foods and supplements of health claims relating to associations between ingestion of folic acid and reduction in risk of neural tube birth defects.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a) (11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the Federal Register. The agency requests comments on the RIA.

VI. Comments

Interested persons may, on or before January 27, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.71 is amended by adding paragraph (c) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(c) Folic acid and neural tube defects (insert cite and date of publication in the **Federal Register** of the final rule).

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

[Docket No. 91N–0101]

RIN 0905–AB67

Food Labeling: Health Claims and Label Statements; Antioxidant Vitamins and Cancer

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing not to authorize the use on foods, including dietary supplements, of health claims relating to the association between antioxidant vitamins and cancer. FDA has reviewed the authoritative documents and scientific data in conformance with the requirements of the Nutrition Labeling and Education Act (the 1990 amendments) and concluded that there is not significant scientific agreement to support the use of health claims relating to antioxidant vitamins and cancer on labels and labeling. Although scientific evidence is suggestive of an effect of beta-carotene on cancer risk, studies available to date have been based on consumption of fruit and vegetables high in beta-carotene and not beta-carotene itself. Clinical trials are currently underway to clarify

this relationship. Although scientific evidence is suggestive of an effect of vitamin C on cancer risk, data on the relationship are not consistent and have mostly been obtained in studies of consumption of foods containing high levels of vitamin C. Such studies do not permit a conclusion on the specific role of the nutrient. Evidence for an effect of vitamin E on cancer risk are limited and inconclusive.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with the provisions of the Nutrition and Labeling Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: John N. Hathcock, Center for Food Safety and Applied Nutrition (HFF–268), Food and Drug Administration, 200 C Street SW., Washington, DC 20204, 202–245–1198.

SUPPLEMENTARY INFORMATION:

I. Background

A. Nutrition Labeling and Education Act of 1990 (the 1990 Amendments)

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101–535), which amend the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary) to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this **Federal Register** is a proposed rulemaking to establish general requirements pertaining to the use on food labels and in labeling of health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs or other nutritional substances (referred to generally as "substances") to a disease or health-related condition (proposed in "General Requirements for Health Claims"). In the proposal on general requirements for health claims, FDA following the provisions of the 1990 amendments has tentatively determined that such claims would only be justified for substances in dietary supplements as well as conventional foods if the agency determines based on the totality of the publicly available scientific evidence (including evidence from well designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (section 3 (b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)) that within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act, and such regulations shall determine, among other things, whether claims respecting 10 topic areas, including antioxidant vitamins and cancer, meet the requirements of the act. In this document, the agency will consider whether a claim on food or food products, including conventional foods and dietary supplements, on the relationship between antioxidant vitamins and cancer, would be justified under the standard proposed in "Food Labeling: General Requirements for Health Claims for Food: Proposed Rule."

B. Antioxidant Vitamins and Cancer—Public Health Aspects

Section 3(b)(1)(A)(x) of the 1990 amendments requires that FDA determine whether claims for effects of dietary supplements, including the antioxidant vitamins in relation to cancer, meet the standard that FDA adopts under section 403(r)(5)(D) of the act for determining the validity of health claims. Because the standard that FDA is proposing under that section is the same as the standard that is established in section 403(r)(3)(B)(i) of the act for conventional foods, FDA is extending consideration of this topic area to all sources of antioxidant vitamins.

To comply with the provisions of the 1990 amendments, FDA requested, in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on 10 specific topic areas, including the topic of antioxidant vitamins and cancer. The agency has considered data and information obtained from these submissions in its evaluation of the scientific basis for a health claim for antioxidant vitamins and cancer.

1. Cancer

Cancer is a disease of major public health importance in the United States. All forms of cancer taken together are ranked as the second most common leading cause of death in the United States and account for one in five deaths (Ref. 1). Deaths from cancer numbered more than 475,000 in 1987. The overall economic cost of cancer, including the direct health care costs and losses from morbidity and mortality, was estimated to be $72.5 billion (Ref. 2). The social impact of cancer can be measured in part by the potential years of life lost by death before age 65. Potential years of life lost were 18 million years for cancer compared to 15 million years for heart disease (Ref. 3).

Risk of occurrence differs markedly for various types of cancer. In 1990, the leading types of cancer in men in the United States were lung (35 percent of all cancer deaths), colorectal (11 percent), and prostate cancer (11 percent). For women, the leading types were lung (21 percent), breast (18 percent), and colorectal cancer (13 percent) (Ref. 3).

Factors that may influence the risk of cancer include not only diet but also life style, environment, and genetics. Antioxidant vitamins may have important, possibly protective, influences on the risk of certain cancers, but other dietary factors such as intakes of energy (calories), type and amount of fat, and other food components may also make important contributions to the relationship between diet and cancer (Ref. 4a).

2. Antioxidant Vitamins

The antioxidant substances that FDA has chosen for consideration are vitamin C, vitamin E, and beta-carotene. Vitamins C and E were chosen because they are vitamins that function as antioxidants (Ref. 4). FDA chose beta-carotene because it is an antioxidant, and because it is a provitamin and an important source of dietary vitamin A activity (Ref. 4). FDA did not choose vitamin A (retinol) and retinoic acid because their biological functions are not through an antioxidant role, and because vitamin A cannot function in a fashion similar to that of beta-carotene (carotenoids) and vitamins C and E (Ref. 5b).

a. *Beta-carotene.* Beta-carotene, a yellow-orange plant pigment, is only one of a large family of carotenes, some of which serve as vitamin A precursors and some of which do not (Refs. 6 and 7). Of all of the carotenoids, beta-carotene has the greatest provitamin A activity.

In addition to serving as a source of vitamin A activity, the antioxidant function of beta-carotene is important.

As a common constituent of the human diet, beta-carotene is a component of the body's primary defenses against the harmful substance known as free radicals and reactive oxygen molecules Refs. 8, 9, and 11). Beta-carotene and similar carotenoids trap, deactivate, and destroy these molecules and prevent the damage they can cause. A way in which beta-carotene might possibly alter the risk of cancer is through its effect on the immune system. Beta-carotene and canthaxanthin have been shown to enhance the immune response in rats (Ref. 12). Beta-carotene has been demonstrated to produce changes in immune cellular marker expression in vivo in humans (Ref. 13) in which there was an increase in the percentage of cells expressing natural killer cell characteristics and activities, changes often related to increased resistance to cancer in experimental animals.

All of the carotenoid pigments similar in chemical structure to beta-carotene have antioxidant activity and the capacity for trapping and deactivating free radicals and reactive oxygen molecules. Of the carotenoids that predominate in human plasma (Ref. 131), i.e., lycopene, beta-cryptoxanthin, zeaxanthin, lutein, and alpha- and beta-carotene, all have this activity and capacity. Carotenoids are prevalent in yellow and greenish-yellow foods, such as carrots, squash, broccoli, sweet potatoes, tomatoes, and kale; these foods are some of the best sources of carotenoids. The fact that, collectively, carotenoids contribute significantly to the daily vitamin A intake and function as antioxidants makes these compounds important components of the daily diet.

b. *Vitamin C.* Vitamin C (*L*-ascorbic acid) is a watersoluble antioxidant vitamin that cannot be synthesized by humans. Dehydroascorbic acid, an oxidized form of ascorbic acid, may be present in the diet, and also has vitamin C activity. Dietary deficiency of vitamin C, which is extremely rare in the United States, leads to scurvy.

Vitamin C functions in a variety of enzymatic reactions that require molecular oxygen. For example, vitamin C is involved in enzyme reactions required for formation of proteins in connective tissue. Vitamin C also serves as an effective free-radical scavenger to protect cells from damage by oxidants. It is in this capacity that vitamin C may provide protection against adverse effects of potential carcinogens. Vitamin C plays roles in maintaining the integrity of intracellular matrices, enhances the immune system, and is necessary for several types of biochemical reactions (Ref. 6).

The richest food sources of vitamin C are green peppers, broccoli, citrus fruits, melons, tomatoes, raw cabbage, and green leafy vegetables such as spinach, turnip, and mustard and collard greens. The amount of vitamin C in the United States food supply has increased significantly since the beginning of the century; this has been the result, in part, of the greater availability of citrus fruits and dark green vegetables and to fortification of some foods with vitamin C. About 73 percent of the vitamin C intake in the United States is derived from fruits and vegetables (Nationwide Food Consumption Survey of 1977 and 1978).

The Recommended Dietary Allowance (RDA) for vitamin C for adults is 60 milligrams per day (Ref. 14). The major contributors of vitamin C to the United States diet are orange juice, grapefruit and grapefruit juice, fortified fruit drinks, oranges, tangerines, and potatoes (Ref. 4a).

Estimated average intakes of vitamin C are well above the RDA for men, women, and children (182, 133, and 186 percent, respectively, of the RDA's) (Ref. 4a). Between 35 and 40 percent of the adult U.S. population are estimated to take nutrient supplements, and approximately 90 percent of these take a supplement that includes vitamin C.

A 1986 National Health Interview Survey (Ref. 15) of vitamin and mineral supplement use in the United States found that men and women (about 31 percent of all adults) consumed vitamin C more than any other nutrient, and the median intake of vitamin C was 200 percent of the RDA due to this supplement intake. Current dietary data indicate that mean intake of vitamin C is well in excess of the RDA's for all population groups, and the additional supplement use provides a large segment of the population with intakes several fold the RDA levels (Ref. 2).

c. *Vitamin E.* Vitamin E has received attention as an antioxidant vitamin that may reduce the risk of cancer. The vitamin represents a family of compounds, tocopherols and tocotrienols. These compounds exist in various forms and have different biological activity. The most active form of vitamin E is alpha-tocopherol followed by beta-tocopherol, gamma-tocopherol, and alpha-tocotrienol. The basic biological function of vitamin E in animal tissues is as an antioxidant where it acts as a defense against potentially harmful reactions with oxygen (Ref. 2). Determination of the requirements for vitamin E is complicated by variations in susceptibility of dietary and tissue fatty acids to peroxidation (reaction with an oxygen molecule to form a fatty acid peroxide), and difficulty in demonstrating changes in vitamin E status in the general healthy population (Ref. 16). The richest food sources of vitamin E are wheat germ, vegetable oils (corn, cottonseed, safflower, soybean and sunflower oils), and products made from vegetable oils. Other good sources are nuts, seeds, whole grains, and wheat germ.

The National Research Council (NRC) in the 1989 edition of "Recommended Dietary Allowances" (Ref. 14) stated that an adequate level of vitamin E implies that the ratio of tocopherol to polyunsaturated fatty acid in the tissues protects lipids from peroxidation, permits normal biological functions, and allows for individual variations of lipids in tissues. According to the NRC, these criteria of adequacy appear to be met by amounts of vitamin E and polyunsaturated fatty acids in balanced diets consumed by healthy individuals. Therefore, the RDA's are primarily based on customary intakes from the U.S. food supply.

The RDA's for vitamin E have been set by the NAS (Ref. 14). The RDA is 10 mg of alpha-tocopherol equivalents for males 11 years of age and older and 8 mg of alpha-tocopherol equivalents for females 11 years and older. The allowance of alpha-tocopherol equivalents for infants and children 1 to 10 years of age is 6 to 7 mg and the allowance for infants less than 1 year of age is 3 to 4 mg. One alpha-tocopherol equivalent is defined as 1 mg d-alpha-tocopherol. The adequacy of the RDA's for vitamin E will vary, if the polyunsaturated fatty acid content of the diet increases greatly over intakes in current balanced diets in the United States.

d. *Interactions among antioxidant vitamins.* The antioxidant vitamins are interactive in that they complement each other during situations of biological stress. Vitamin C, most of which is located in the aqueous portion of the cell, spares vitamin E until the vitamin C reserve is depleted (Ref. 17). Vitamin E is located in the lipid portions of all membranes, and it deactivates free radicals. Sparing action has also been observed between beta-carotene, which is also found in the lipid portions of the cell, and vitamin E in that beta-carotene exhibits deactivation of free radicals similar to that of vitamin E. Beta-carotene, vitamin C, and vitamin E all inhibit damage by oxidative chemicals, including carcinogens (Ref. 7). More specifically, beta-carotene traps reactive oxygen molecules, vitamin E and beta-

carotene remove free radicals, and vitamin C inhibits oxidative reactions and also removes free radicals.

The antioxidant vitamins may also interact negatively in that high doses of one can counteract the uptake, transport and storage of another. For example, high intakes of beta-carotene administered to humans for 6 months or more can deplete plasma levels of vitamin E (Ref. 18b). In another report (Ref. 20), high intakes of beta-carotene for over 4 years did not alter vitamin E levels in humans. However, high intakes of vitamin A in rats were shown to deplete plasma levels of vitamin E (Ref. 19).

Because of the complementary and antagonistic interactions among the antioxidant vitamins, high intakes of one without commensurate increases in the others may not support optimum status and functions for these nutrients (Refs. 4a and 21). Foods may, therefore, provide a better balance of these nutrients than do supplements, and foods supply other substances such as fiber, minerals, and many nonnutrients that may be important in reducing the risk of some cancers (Refs. 4a and 17).

3. Basis for Associations Between Antioxidant Vitamins and Cancer

a. *Mechanisms of carcinogenesis and relationship to antioxidants.* The complex process of carcinogenesis is often described as occurring in distinct phases (Refs. 4 and 28) including: (a) Initiation, (b) promotion, (c) progression, and (d) metastasis. Initiation of the carcinogenic process results from chemical or physical damage to cellular genetic material (deoxyribonucleic acid (DNA)). Cell replication then results in fixation of the damage as a mutation. Promotion involves stimulation of the growth of initiated cells. Progression is the malignant transformation of the initiated cell mass into an invasive form that is not subject to the normal limits or controls of cellular replication. Metastasis is the spread or dissemination of cells from the original tumor to new sites in the body.

Most dietary carcinogens occur as procarcinogens, i.e., as substances that require activation to a reactive form that is termed the proximate carcinogen (Refs. 22 and 23). The ultimate carcinogen, an extremely reactive and unstable species, is produced by rearrangement of the proximate carcinogen. The ultimate carcinogen is the form that is directly involved in the reaction with nucleic acids or other substances with similar chemical reactivity (nucleophiles).

This general pattern of carcinogen activation, chemical reaction of the carcinogen molecule with nucleic acids, mutagenesis, and carcinogenesis is firmly established through experiments with animals and with cultures of human and animal cells (Refs. 22 and 24).

A major effect of vitamin C that could be the basis of protection against cancer is its ability to inhibit nitrosamine formation (Ref. 25). Nitrosamines (N-nitroso amines and N-nitroso amides) are types of carcinogens which occur in foods and are produced within the body by reaction of nitrite with other dietary or endogenous amines and amides (Refs. 25 and 26). Some nitrite occurs in food, but more is produced from reduction of nitrate by bacteria in the mouth and small intestine (Ref. 26). Nitrate occurs in food (Ref. 26), and some is produced in the body from L-arginine (Ref. 27). The nitrosation reactions occur rapidly in the acid environment of the stomach and upper duodenum (Ref. 25). Most nitrosamines tested in experimental animals are carcinogenic, and some are very potent carcinogens affecting multiple sites (Ref. 26).

b. *Associations between antioxidant vitamins and risk of cancer Beta-carotene.* Epidemiological studies in the 1970's and early 1980's showed an inverse association between vitamin A intake and lung cancer and cancers at various sites (Ref. 28). A reexamination of the early vitamin A intake data in relation to cancer, however, revealed that the sources of the vitamin A were fruits and vegetables which contain beta-carotene and other carotenoids. As stated above, beta-carotene is a precursor of vitamin A and is not vitamin A itself. Therefore, the focus of research on the relationship between vitamin A and cancer shifted to the carotene content of the foods consumed.

This hypothesis of the relationship between ingestion of beta-carotene and decreased cancer risk has persisted. Results of animal studies indicate that beta-carotene is effective in preventing cancers induced by certain chemical carcinogens. This information however, is helpful only with regard to discerning mechanisms involved in cancer development, because the type and amount of carcinogen used in the animal experiment are not typical for humans. The strongest evidence to support the hypothesis that beta-carotene decreases the risk of cancer is from epidemiological studies involving fruit and vegetable consumption, and not from studies of beta-carotene itself in humans. When completed, clinical trials currently underway should provide more direct evidence on whether beta-carotene alters the risk of cancer in humans.

c. *Vitamin C.* A hypothesized relationship between ingestion of vitamin C and risk of cancer has developed from several types of studies. For example, human studies have shown a protective association between consumption of foods that contain vitamin C and cancers of several sites (Ref. 29). Studies in experimental animals have shown that animals fed both vitamin C and precursors of carcinogenic nitrosamines develop fewer tumors than animals fed the precursors alone (Ref. 30). Vitamin C has been shown to reduce bladder tumors in animals induced by one carcinogen (Ref. 31), but not by another (Ref. 32). Biochemical studies have shown that vitamin C prevents the oxidation of specific chemicals to active carcinogenic forms (Ref. 31), and vitamin C blocks the formation of carcinogenic nitrosamines from nitrates and nitrites in the digestive tract (Refs. 30 and 33b). The combination of evidence from epidemiological studies and evidence from several types of studies with animals which involved administration of carcinogens and carcinogen precursors provides a strong basis on which to postulate that vitamin C reduces the risk of cancer in humans.

d. *Vitamin E.* The hypothesis that vitamin E may reduce the risk of some types of cancer is based on two kinds of scientific findings. Animal studies have demonstrated an inhibitory effect of vitamin E on cancers induced by ultraviolet light and certain chemicals. These studies date back to the earliest days of vitamin E chemistry (Ref. 34). More recently, the implications of reactive oxygen molecules in cancer development provide a theoretical basis for the involvement of vitamin E (a strong antioxidant) in the development of cancer, because carcinogens are activated by oxidative processes and oxidation of cell components may contribute to cancer development (Refs. 4a and 22).

C. Regulatory History of Antioxidant Vitamins

1. Nutrition Labeling

FDA published a proposal to amend the food labeling regulations to codify and clarify the agency's policy on the appropriate use of health claims on food labeling in the **Federal Register** of August 4, 1987 (52 FR 28843). On August 8, 1989, FDA published in the **Federal Register** (54 FR 32610) an advance notice of proposed rulemaking requesting public comments on (among other areas) how to reasonably permit the use of claims on food labels that link food

components to reducing the risk of chronic disease. In the **Federal Register** of February 13, 1990 (55 FR 5176), FDA withdrew the August 4, 1987 proposal (52 FR 28843) and reproposed to amend the food labeling regulations to provide for the use of health claims on food labeling. The purpose of the reproposal was, in part, to establish procedures for permitting valid and reliable consumer information on food labels about the value that ingestion of dietary components may have in either lowering the risk or forestalling the premature onset of particular chronic disease conditions. The topic of antioxidant vitamins and cancer was not specifically mentioned in any of these documents.

Comments from a consumer advocacy group and several industries suggested that topics other than the six specified in the reproposed rule making were worthy of consideration and stated that the role of antioxidant vitamins and beta-carotene in preventing diverse diseases, especially cancer, should be considered. One comment suggested that health claims might be appropriate for the relationship between cancer and fruits and vegetables and the antioxidant vitamins. Another comment argued that a health claim for beta-carotene rich foods would be consistent with the dietary recommendations of organizations such as the National Cancer Institute. Several comments asserted that a substantial body of evidence exists showing an inverse association between foods high in beta-carotene and a reduced risk of certain forms of cancer.

A trade association for the dietary supplement industry commented that, in its opinion, the evidence is "overwhelming" that consumption of fruits and vegetables high in antioxidant vitamins reduces the risk of certain forms of cancer, and that the scientific evidence suggests that vitamins C and E and beta-carotene are responsible for this effect. A pharmaceutical company commented that it felt antioxidant vitamins, particularly vitamin C, are effective in vivo antioxidants and are involved with other diseases such as heart disease, cataracts, rheumatoid arthritis, and Parkinson's disease. A major food manufacturer commented on the relationship of beta-carotene and cancer, citing currently completed epidemiological evidence and ongoing clinical trials.

No comments were received from consumers or from professional organizations of physicians or other health care workers.

These comments were superseded to by section 3(b)(1)(A)(x) of the 1990 amendments, which directed FDA to consider the relationship between dietary supplements of antioxidant vitamins and cancer, among other topics. These topics are considered in this and other documents published in this issue of the **Federal Register.**

2. Regulatory Status

Substances that are added to food may be categorized as generally recognized as safe (GRAS) ingredients, food additives, or subject to a sanction or approval granted by FDA or the U.S. Department of Agriculture (USDA) prior to September 6, 1958. Substances may be GRAS in accord with the general principles stated in 21 CFR 170.30, listed as GRAS in 21 CFR part 182, or affirmed as GRAS in 21 CFR part 184. The status of the most common uses in foods of carotenoids, vitamin C compounds, and tocopherol compounds is summarized below.

The following carotenoid compounds and sources rich in these carotenoid compounds are approved color additives for food use exempt from certification: beta-carotene (21 CFR 73.95), betaapo-8'-carotenal (21 CFR 73.90), and carrot oil (21 CFR 73.300). Beta-carotene is affirmed as GRAS for use as a nutrient supplement (21 CFR 184.1245) and listed for use in dietary supplements § 182.5245. Carrot oil, essential oil or extractive, is listed for use as a flavoring substance § 182.20.

Ascorbic acid (vitamin C) is listed as a GRAS ingredient for use as a chemical preservative (antioxidant) (21 CFR 182.3013), in dietary supplements (21 CFR 182.5013), and as a nutrient (21 CFR 182.8013). Ascorbyl palmitate, ascorbyl stearate, calcium ascorbate, and sodium ascorbate are listed as chemical preservatives (21 CFR 182.3149, 166.110, 182.3189, and 182.3731, respectively). Ferrous ascorbate is affirmed as GRAS for use as a nutrient supplement (21 CFR 184.1307a), although, at usual levels of intake, ferrous ascorbate contributes little vitamin C activity. A nicotinamide-ascorbic acid complex is listed as a special dietary and nutritional food additive in 21 CFR § 172.315.

Tocopherols are listed as GRAS for use as dietary supplements (21 CFR 182.5890), as nutrients (21 CFR 182.8890), and as chemical preservatives (antioxidants, in 21 CFR 182.3890, and inhibitors of nitrosamine formation (21 CFR 184.1890)). Alpha-tocopherol acetate is listed as GRAS for use in dietary supplements (21 CFR 182.5892) and as a nutrient (21 CFR 182.8892).

D. Evidence Considered in Reaching the Decision

The agency reviewed all relevant scientific evidence on associations between ingestion of antioxidant vitamins (vitamins C and E) and beta-carotene and reduced risk of cancer. The scientific evidence and conclusions that the agency reviewed included those in the "Surgeon General's Report on Nutrition and Health" (Surgeon General's Report) (Ref. 4a), "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 35), and the U.S. Department of Health and Human Services (DHHS) "Healthy People 2000: National Health Promotion and Disease Prevention Objectives" (Ref. 3). The agency also reviewed other authoritative documents, NRC's "Diet and Health" (Ref. 2), and "Recommended Dietary Allowances" (Ref. 14), and the Life Sciences Research Office's "Vitamin A and Cancer" (Ref. 36), "Vitamin C and Cancer" (Ref. 37) and "Vitamin E and Cancer (Ref. 38).

The agency updated the evidence reached in these documents by reviewing all human studies in the literature subsequent to these documents and all new review articles. The updated literature search began with 1987. The agency also considered the results of animal studies to the extent that they clarified human studies or suggested possible mechanisms of action.

To assure that its review of relevant evidence was complete, FDA requested, in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas identified in section 3(b)(1)(A)(vi) and (b)(1)(A)(x) of the 1990 amendments. The topic of antioxidant vitamins and cancer was among the 10 subjects on which the agency requested scientific data and information. The agency reviewed all of the documents it received, including letters, press releases, scientific articles, review articles, and recommendations. Where appropriate, data submitted in scientific articles were considered in the review of the scientific literature (section II.)

E. Comments Received in Response to FDA's Request for Scientific Data and Information

FDA received 17 comments in response to the March 28, 1991 **Federal Register** notice (56 FR 12932) concerning antioxidant vitamins and cancer health claims. Of the comments received, nine were from industry, three from professional organizations, two from trade associations, one from an individual consumer, one from a state government, and one from the Government of Canada.

Over 435 references were received, including recent review articles on

antioxidant vitamins and cancer. Some of the responses included references only, while others contained references and comments, or just comments. The comments generally cited data or opinions from specific references. The majority of the comments supported a health claim relative to the antioxidant vitamins and cancer. In general, comments from manufacturers and trade associations, as well as from a few research organizations, argued that the evidence for beneficial effects of antioxidant vitamins in relation to cancer is strong, or even compelling, that these substances are safe, and therefore, the only reasonable course of action is to allow health claims in this area.

The regulatory status of health claims for antioxidant vitamins and cancer in Canada was described in comments from the Director General, Food Directorate, Health and Welfare, Canada. The official position of Canada on the relationship of diet and nutrients to disease and the metabolic effects of nutrients is stated in the volume "Nutrition Recommendations, the Report of the Scientific Review Committee–1990." In sections related to Water-Soluble Vitamins and Fat-Soluble Vitamins, this report concluded that, for vitamin C and the fat-soluble vitamins, evidence for protection against cancer lacks specificity and is inconclusive. The Government of Canada pointed out that health claims would be illegal under Canadian law and thus advised against such claims.

All of the nine responses received from industry included literature references on antioxidant vitamins and cancer. One chemical company provided data to demonstrate the efficacy and safety of antioxidant vitamins, especially vitamins C and E, and beta-carotene. A food manufacturer suggested that FDA also consider the interactions between antioxidant vitamins and selenium. The comment also suggested that antioxidants may be depleted by oxidative stress, thereby enhancing risk of a variety of diseases including heart disease, breast and cervical cancer. A diet systems company provided a tabular summary concluding that antioxidant vitamins (but not any one specifically) are protective against cancers of the breast and colon. Another manufacturer argued that animal research and human epidemiologic and blood level studies support a protective effect for vitamin E, vitamin C, and beta-carotene, but that continued research is warranted.

A pharmaceutical manufacturer commented that: (1) Free radical damage is widely accepted as a major theory of carcinogenesis and that the antioxidant vitamins are effective inhibitors of this process; (2) many persons are not consuming RDA levels of the vitamins; (3) epidemiologic evidence is supportive of beneficial effects by the antioxidant vitamins, and the National Cancer Institute and the USDA have recommended increased intakes of certain foods on this basis; (4) there is little or no evidence that consumers will replace conventional medical care with dietary "treatments" for cancer or other disease; and (5) supplementation is beneficial and essentially risk-free. A pharmaceutical and a supplement manufacturer argued that they recommend a benefit/risk approach instead of consideration of only what has been established as an "incontrovertible scientific fact." These two pharmaceutical manufacturers also expressed extreme concern and dissatisfaction with the rulemaking process.

FDA notes in response to these comments that the "benefit/risk" or "essentially risk-free" rationale does not qualify as a basis for a health claim. The 1990 amendments provide that a health claim is justified only if the agency determines, based on the totality of publicly available scientific evidence relating the nutrient and the disease, that there is significant agreement among qualified experts that the claim is supported by such evidence. Therefore, the agency rejects the concepts of "benefit/risk" or "essentially risk-free" as basis for a health claim because of their inconsistency with requirements of the 1990 amendments.

A private research foundation commented that evidence supports the conclusion that increased intakes of micronutrients including the antioxidant vitamins lowers the risk of cancer, especially in the stomach and esophagus. The comments stated, however, that the emphasis should be on avoiding intake of carcinogens, rather than on consumption of anticarcinogens. On the other hand, another professional organization argued that there should be no doubt concerning the antioxidant efficacy of certain vitamins.

A trade association commented that the NRC's book "Diet and Health" (Committee on Diet and Health, 1989) virtually ignored this important topic of antioxidant vitamins and cancer, even though data and conclusions of important benefits have been published by respectable scientists. A trade association for the dietary supplement industry submitted abstracts on selenium and cancer. It also cited evidence that vitamin C is effective, both in animals and in humans, against a wide variety of cancer types/sites, through a variety of mechanisms, and with exposure of animals to a variety of carcinogens.

A state government agency provided only general comments on the nutrient health relationships it believes must be established to justify any health claim. This agency recommended that scientific agreement should be considered the cornerstone of any health claim. This state government agency and a professional organization, however, urged that FDA be extremely cautious in making its decision.

The agency has considered each of these comments in its development of this proposal.

F. Criteria for Evaluation of Scientific Evidence

FDA has evaluated the data from human studies against general criteria for good experimental design, execution, and analysis. The criteria used in evaluating epidemiological studies included:

(1) Reliability and accuracy of the methods used in food intake analysis and measurement of disease endpoints;

(2) Choice of control subjects (e.g., hospital-based versus population-based);

(3) Representativeness of subjects;

(4) Control of confounding factors, particularly fat, which has an inverse correlation with, and fiber intake which has a positive correlation with, fruit and vegetable intake, in data analysis;

(5) Potential for misclassification of individuals with regard to dietary exposure or disease end points;

(6) Presence of recall bias and interviewer bias; and

(7) Degree of compliance and how compliance was assessed.

FDA evaluated the weaknesses and strengths of individual studies (see "Assessment" column of tables following each antioxidant vitamin). The agency then assessed the strength of the overall combined evidence (e.g., epidemiologic studies and animal studies), taking into account the strength of the association, the consistency of findings, specificity of the association, evidence for a biological mechanism, and presence or absence of a dose-response relationship. FDA's conclusions reflect the strength, consistency, and preponderance of data.

II. Review of Scientific Evidence: Beta-Carotene

A. Federal Government Documents and Statements

In 1988, "The Surgeon General's Report on Nutrition and Health (Ref. 4a) considered the role of carotenoids in cancer. The report concluded that some epidemiologic studies provide suggestive evidence that frequent consumption of vegetables and fruits, particularly dark green and deep yellow vegetables which contain carotenoids, including the beta-carotene precursor of vitamin A, may lower risk for cancers of the lung and bladder as well as some cancers of the alimentary tract. The report pointed out, however, that these studies have not ruled out the possibility of protection from some other active component of fruits and vegetables. Until the results of chemoprevention clinical intervention trials examining these relationships become available, the report stated that it could conclude only that an increase in consumption of fruits and vegetables might benefit persons who now consume below average amounts of these foods. No risks from consumption of beta carotene or carotenoids were identified.

USDA and DHHS in "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 35) recommended the consumption of generous portions of vegetables and fruit, but did not make a specific reference to the role of increased consumption of these foods and the lowered risk of cancer.

B. Other Authoritative Documents and Statements

The NAS 1989 report on "Diet and Health" (Ref. 2) found that there is strong evidence that a low intake of carotenoids, which are present in green and yellow vegetables, is related to an increased risk of developing lung cancer. The report stated that the mechanism for the link between frequent consumption of vegetables and fruits, especially green and yellow vegetables and citrus fruits, and decreased susceptibility to cancers of the lung, stomach, and large intestine is not well understood because the responsible agents in these foods and the mechanisms for their protective effect have not been fully determined.

The 10th edition of the "Recommended Dietary Allowances" (Ref. 14) contains a discussion of carotenoids with regard to the recommended allowances for vitamin A. The report stated that most carotenoids, unlike vitamin A, trap free radicals and remove reactive oxygen molecules which can cause changes in cells. The report further stated that because only about 10 percent of carotenoids in nature show provitamin A activity, any anticancer effects that carotenoids possess might be related more to their antioxidant or other properties than to their conversion into vitamin A. The RDA report suggested that, a generous intake of carotenoid-rich foods may be of benefit.

The Life Sciences Research Office (Ref. 36) reviewed the recent scientific literature on "Vitamin A (including beta-carotene) and Cancer" and concluded that: (1) The data relating vitamin A to cancer are inconclusive, (2) the strongest evidence supports a possible protective role of fruits and vegetables in reducing the rates of cancer of various sites, particularly cancers of the lungs, colon/rectum and breast, and (3) the beta-carotene content of these foods may, in part, be exerting some of the effects.

C. Review of the Scientific Literature

The agency reviewed available scientific evidence on beta-carotene and carotenoids and cancer provided by epidemiological studies (prospective and retrospective) and clinical studies published since the publication of "The Surgeon General's Report on Nutrition and Health" (Ref. 4a). The data that FDA reviewed were evaluated according to specific criteria. Studies that involved healthy matched controls (e.g., age, sex, and ethnic origin) that were controlled for confounders, such as smoking, and that used validated dietary assessment instruments, appropriate storage conditions for test samples, and adequate sample size were given the greatest weight by FDA. When the possibility could not be excluded that the observed association was mainly a result of the disease altering indications of beta-carotene, or resulted from an effect of another substance in the foodstuff influencing the disease, the study was given less weight.

1. Primary Human Studies

Epidemiological studies of a retrospective nature that have assessed consumption of fruits and vegetables in relation to cancer mortality are shown in Table 1. Most of these case-control retrospective studies show an inverse association between intakes of fruits and vegetables rich in carotenoids and the risk of lung cancer. However, some studies also show that intakes of these foods are associated with a lowered risk of colorectal and stomach cancers.

LeMarchand and coworkers (Ref. 39) reported that higher intakes of foods containing beta-carotene are associated with lower risk of lung cancer in a multi-ethnic population of men and women in Hawaii. These researchers also reported stronger associations of lower lung cancer risks with consumption of all vegetables, dark green and cruciferous vegetables, and tomatoes than with consumption of beta-carotene.

Bond and coworkers (Ref. 40) reported similar findings of a lower lung cancer risk with higher intakes of foods with a high carotenoid index in a population of chemical company employees in Texas. Recently, upon reevaluation of data relating dietary intake to prostate cancer, these researchers (Ref. 41) reported that beta-carotene intake is not associated with prostate cancer risk. Prostate cancer risk, however, was reported to be inversely related to intake of foods containing beta-carotene in men over 70 years of age in two studies conducted in Japan (Refs. 42 and 43).

Adjusted risk of ovarian cancer was reduced with high intakes of beta-carotene in the study of Slattery et al. (Ref. 44). In a study conducted in England, Coggon et al. (Ref. 45) reported that intakes of fruits and salad vegetables were inversely associated with risk of stomach cancer. Kune et al. (Ref. 46) and LaVecchia et al. (Ref. 47) reported that risks of colorectal cancer were inversely associated with higher intakes of vegetables containing beta-carotene or those with a higher carotenoid index and vitamin C. In both of these studies, however, as with other studies showing a significant inverse relationship of higher intakes of fruits and vegetables and cancer risks, complementary effects of the antioxidants or effects of other components of the foods cannot be ruled out as the cause of the observed association.

In a unique type of case-control retrospective study, Smith and Waller (Ref. 50) included immediate family members of cancer patients and immediate family members of control hospitalized subjects in assessing the association between serum beta-carotene and cancer. Lower serum levels of beta-carotene were observed in patients with cancer of the lung, stomach, esophagus, small intestine, cervix and uterus. Lower serum levels of beta-carotene were also found in relatives of the cancer patients compared to serum levels in control subjects and their relatives. The inclusion of immediate family members as part of the study design corrects for effects from the illness. Additionally, the matching of subjects as to smoking status, age, sex, length of sample storage as well as the use of relatives, make the findings in this study consistent with those of prospective studies.

Prospective studies shown in Table 2 assessed dietary intake of foods rich in carotenoids and the subsequent development of cancer. There was an inverse association between intake of carotenoid-rich fruits and vegetables and risks of breast, lung, and other epithelial cancers in three studies (Refs. 51 through 53). However, Paganini-Hill et al. (Ref. 54) reported no association between intake of beta-carotene-rich foods and cancer at various sites.

In prospective studies (Table 3) in which serum or plasma carotenoid levels were measured in subjects who later developed cancer, Wald et al. (Refs. 55 through 57) and Connett et al. (Ref. 58) reported an inverse association between blood beta-carotene levels and lung and stomach cancers. In a 12–year followup prospective study, overall cancer mortality was inversely associated with plasma carotene adjusted for cholesterol levels, and bronchus and stomach cancers were inversely associated with total plasma carotene (Refs. 59 and 60).

Premalignancy studies, or those in which neoplastic changes in a tissue do not affect appetite and food intake or carotenoid metabolism in blood, offer the advantage of early diagnosis and assessment of dietary associations. An example of premalignancy studies are case-control studies of cervical dysplasia and in situ carcinogenesis in which the stage of cancer development is diagnosed by microscopic examination of cells. Beta-carotene exposure was assessed as intake of deep green and yellow vegetables, dietary beta-carotene, or plasma beta-carotene levels. Beta-carotene exposure from either of the above dietary sources was inversely correlated with the incidence of premalignancy in all but one of the studies reported (Table 4) (Refs. 62 through 66). In a small group of cases and controls, De Vet et al. (Ref. 67) found no association between beta-carotene supplements, consumed at 10 mg per day for 1 month, and changes in cervical dysplasia. The authors suggested that the supplementation period may have been too short to provide conclusive results.

A number of chemoprevention intervention trials are underway that are aimed at preventing or reducing the recurrence of malignancies (Table 5). These trials will be ongoing for some time because of the long latency period for cancer. Subjects are given beta-carotene in capsule or tablet form as a supplement to the beta-carotene and other carotenoids consumed through their diets. The information gathered from these clinical intervention trials should provide important information regarding the efficacy of the carotenoids either alone or in combination with other antioxidants in altering the cancer incidence.

One intervention trial of relatively short duration examined the effects of beta-carotene with and without vitamin A supplementation on oral leukoplakia (a condition of white, rough, sometimes fissured patches on the mucous membranes of the oral cavity that cannot be rubbed off, and which occur most often in smokers) in persons who frequently chewed betel (Ref. 68). After 3 months there was a reduction in symptoms in both beta-carotene groups, and after 6 months the investigators observed a significant regression of this condition.

A trial of longer duration, which examined the role of beta-carotene in preventing new occurrences of nonmelanoma basal cell and squamous cell carcinomas of the skin, has been completed (Ref. 20). Five hundred eighty-two subjects were supplemented with 50 mg beta-carotene per day. Median plasma concentrations after 1 year of supplementation increased 10-fold, with the largest increase occurring in nonsmokers, women and leaner subjects (Ref. 69). No effects on new nonmelanoma basal cell and squamous cell carcinomas of the skin from the supplementation of beta-carotene were observed. It has been hypothesized (Ref. 71) that one reason for the lack of effect observed may be that the amount of beta-carotene administered in the trial (50 mg per day) may be less than that suggested by other studies (e.g., 30 to 300 mg per day) to potentially reduce the risk of the recurrence of this type of cancer. A number of other explanations for the lack of effect are also possible. Other clinical trials employ beta-carotene alone or in combination with vitamins A, C, or E (for summary, see Table 5).

2. Supporting Data From Animal Studies

Experimental cancer in animals occurs by administering a chemical compound, exposure to irradiation or ultraviolet light, or a combination of the two. The efficacy of beta-carotene or other carotenoids reducing the incidence of tumors has been demonstrated at various sites in different animal models. These tumor sites include salivary gland, skin, mammary tissue, colon, and stomach (Ref. 72a). Moreover, feeding a naturally occurring source of beta-carotene, algae *Dunaliella bardawil*, resulted in arked inhibition of spontaneous mammary tumors (Ref. 73).

3. Safety Issues

No risks from consumption of beta-carotene intake per se or carotenoids were identified in any of the above reports. Carotenoids, even when ingested in very large amounts for weeks to years, are not known to be toxic (Ref. 135). An important reason for their lack of toxicity is their relatively limited conversion to vitamin A in the intestine, liver, and other organs. Carotenoids taken in large doses for several weeks are absorbed well enough to color the adipose tissue stores, including the subcutaneous fat. Thus, the skin, especially the palms of the hands and the soles of the feet, appears yellow.

D. Conclusions

Evidence relating beta-carotene intake per se to reduced risk of cancer in humans is, at this time, inconclusive. There is strong evidence that high intakes of fruits and vegetables rich in carotenoids are associated with a reduced risk of developing cancer. However, whether the components of fruits and vegetables responsible for reducing the apparent effect are beta-carotene and other carotenoids or some other compound remains unknown. The positive effects of beta-carotene administration in lowering the frequency and severity of experimental cancer in animals suggest that effects are the result of antioxidant properties. The conclusions cannot be directly applied to humans partly because the type and amount of carcinogen exposure in the experimental conditions was not similar to human exposure.

The most promising prospects of clarifying the possible role for carotenoids in human cancer risk rests with the clinical intervention trials that are currently in progress. In these trials, the administration of purified beta-carotene supplements to individuals at increased risk for developing cancer can provide more information regarding the direct role of beta-carotene. However, based on all of the scientific evidence published since 1987 on the role of carotenoids in human cancer risk, the agency finds only that the conclusion of the Surgeon General's Report (Ref. 4a) remains valid; the Surgeon General's report concluded that some epidemiologic studies provide suggestive evidence that frequent consumption of vegetables and fruits, particularly dark green and deep yellow vegetables which contain carotenoids, including beta-carotene, may lower risk for cancers of the lung and bladder, as well as some cancers of the alimentary tract.

Moreover, the recommendation in the "U.S. Dietary Guidelines" to consume generous portions of fruits and vegetables remains appropriate advice.

E. Tentative Decision To Deny a Health Claim Relating to Ingestion of Carotenoids to Risk of Cancer

Evidence of a direct relationship between beta-carotene intake and lowered risk of developing cancer at various sites in humans is inconclusive. The primary source of beta-carotene in the U.S. diet is green and yellow fruits and vegetables. From epidemiological data, there is strong evidence that consumption of fruits and vegetables has an associative relationship to lowered risk of cancer at various sites in humans. However, whether the protective effects of fruits and vegetables against cancer risk is the result of beta-carotene content or some other component remains unknown. Experimentally induced cancer at various sites in animals has been shown to be delayed and decreased in frequency with beta-carotene administration. This effect in animals is through the antioxidant potential of the beta-carotene. Clinical intervention trials for cancer that are in progress may, in a few years, provide additional information of effect of beta-carotene per se, rather than foods containing this substance, on cancer.

FDA has tentatively determined, based on all of the publicly available scientific evidence regarding an association between beta-carotene and cancer, that there is not significant scientific agreement, among experts qualified by scientific training and expertise to evaluate such claims, that a claim associating beta-carotene to the risk of cancer is supported by such evidence.

The agency recognizes that the evidence is strong that consumption of fruits and vegetables, good sources of beta-carotene, is associated with lowered risk of cancer at a number of sites. However, the agency believes that the data are not sufficiently convincing that beta-carotene per se is responsible for this association. Further, even if the evidence for a cause-and-effect relationship of beta-carotene intake with lowered risk of cancer was assumed to be adequate, the agency finds the data to be insufficient to determine the quantity of beta-carotene needed to produce the effect. If such data were available, it would be necessary for the agency to determine whether the food supply already provides enough beta-carotene to produce that effect.

In summary, the agency requests submission of data which directly bear on: (1) Whether beta-carotene per se, rather than some other component of food, decreases the risk of cancer in humans, and (2) the range of beta-carotene intake which produces this effect.

III. Review of the Scientific Evidence: Vitamin C

A. Federal Government Documents

"The Surgeon General's Report on Nutrition and Health" (Ref. 4a) reviewed human studies relating to associations between vitamin C and cancers of specific sites. These included studies of foods that contain vitamin C and cancers of the esophagus, stomach, and cervix. The report also reviewed: (1) Studies that showed that colonic polyps regressed or decreased in area with vitamin C therapy; and (2) studies that reported variable effects (positive and negative) of supplements of vitamin C and vitamin E on formation of fecal mutagens (Ref. 4a). The report also noted that most studies demonstrating beneficial effects of vitamin C did not quantify its actual intake (Ref. 4a). The report concluded that no wholly consistent picture of the role of vitamin C in human cancer has been defined.

The Surgeon General's report also observed that, despite limitations in the data, the American Cancer Society guidelines recommend consuming foods rich in vitamins A and C, and that the National Cancer Institute suggests eating a variety of fruits and vegetables to ensure an adequate supply of vitamin C (Ref. 4a). There is no adequate evidence that larger intakes of vitamin C provide any additional benefits (Ref. 4a).

The 1990 "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 35) recommends consumption of diets with "plenty" of vegetables and fruits. Such diets contain generous levels of the antioxidant vitamins, which were recommended because fruits, vegetables and whole grain cereals are likely to reduce the fat content of the diet, a change associated with decreased risk of cancer. Any possible direct association of antioxidant vitamins with lowered risk of cancer was not discussed.

The DHHS "Healthy People 2000" (Ref. 3) recommends increased consumption of complex carbohydrates and fiber-containing foods to 5 of more daily servings of vegetables (including legumes) and fruits and 6 or more daily servings of grain products. Vegetables, fruits, and grains are good sources of complex carbohydrates and fiber as well as of several vitamins and minerals. The report noted that dietary patterns with higher intakes of vegetables, fruits, and grains are associated with a variety of health benefits including a decreased risk for some types of cancer (Refs. 2 and 4a).

B. Other Authoritative Documents

The NAS in its 1989 Report "Diet and Health" (Ref. 2) reviewed and summarized the role of dietary factors as related to risk of various types of cancer. The NAS reviewed epidemiologic data and evidence from animal studies and studies on mechanisms of carcinogenesis.

The report reviewed associations among dietary factors and stomach cancer. It described major dietary associations between gastric cancer and consumption of dried, salted, or smoked fish or pickled vegetables (foods high in salt and nitrates). It also indicated that a second major dietary association observed with stomach cancer is the protective effect of fresh fruits, vegetables, and vitamins, particularly vitamin C. The report noted in summary that stomach cancer is associated with diets containing large amounts of salt-preserved foods and low levels of fresh fruits and vegetables. The report found, however, that evidence was inconclusive concerning the significant decline in stomach cancer mortality in the United States over the last half-century relating to dietary shifts away from consumption of high salt-preserved foods and toward increased consumption of fruits and vegetables (Ref. 2).

In summary, the report stated that although the contribution of diet to total incidence and mortality from cancer in the United States cannot be determined with certainty, it is reasonable that approximately one-third of all cancer mortality may be related to diet. Data on the carcinogenicity of most components of human diets are quite limited, however, and the exact mechanism of carcinogenesis in humans have not yet been established for any diet-related cancer (Ref. 2).

The NAS in its "Recommended Dietary Allowances" (Ref. 14) noted that vitamin C may prevent the formation of carcinogenic nitrosamines by reducing nitrites. The NAS concluded that ingestion of fruits and vegetables rich in vitamin C has been associated with reduced incidence of some cancers, but that there is no evidence that vitamin C is responsible for such effects.

The Life Sciences Research Office of the Federation of American Societies for Experimental Biology, reviewed the

relationship between ingestion of vitamin C or foods rich in vitamin C and cancer (Ref. 37). The report concluded that epidemiologic studies have provided evidence for a role of nutrients in the reduction of the risk of specific cancers. The report found that one of the most consistent epidemiologic findings has been an association between high intakes of vitamin C-rich foods and a reduction in risk of stomach cancer (Ref. 29). The report noted that intake of citrus fruits has been associated with a significantly reduced risk of oral cancer, and that risk of esophageal cancer was reduced with increased intakes of vitamin C-rich fruits and juices. Intake of vitamin C-rich foods, the report concluded, appears to have no relationship to cancers of the colon, prostate, or ovary. The report found that results with respect to pancreatic cancer are equivocal, and results with respect to vitamin C and breast cancer are inconsistent (Refs. 2 and 29).

C. Review of the Scientific Literature

The agency reviewed the publicly available scientific evidence on vitamin C and cancer provided by epidemiologic and clinical studies in accord with the standard described in the general document on health claims on foods (published elsewhere in this **Federal Register**). Studies that included healthy matched (e.g., age, sex, and race) controls, that controlled for confounders such as smoking, and that used validated dietary assessment instruments and adequate study size were given the highest weight. When the possibility could not be excluded that the observed association was mainly a result of the disease altering indicators of vitamin C status, or resulted from the effect of another substance in the food, the study was given less weight.

1. Evidence for an Association Between Ingestion of Vitamin C or Foods High in Vitamin C and Reduced Risk of Cancer

Research studies published since 1987 include more than 30 case-control studies, 1 prospective study, and 2 randomized clinical intervention trials. Because associations between dietary patterns and cancer appear to be site-related, the recent studies are grouped by site and summarized as follows: Table 6, lung; Table 7, colon and rectum; Table 8, breast; Table 9, prostate; Table 10, pancreas; Table 11, stomach; Table 12, head and neck; Table 13, cervix or ovary. Table 14 summarizes results of a study of patients with bladder cancer and a second study of cancer at various sites. Details of the studies including type and location, description of subjects, methods, and results are presented in these Tables.

a. *Human studies*—(i) *Lung cancer (Table 6).* Adjusted risk analysis (for age and smoking) showed no difference in vitamin C intakes between 450 patients with lung cancer and 902 control subjects (Ref. 74). Dietary information in this study was obtained from a food frequency questionnaire.

In contrast, an inverse association between vitamin C intake and specific types of lung cancer was reported by Fontham et al., (Ref. 75) in a case-control study involving 1,253 patients with lung cancer and 1,274 controls matched for race, sex, and age. Dietary information was obtained from a food frequency questionnaire. No descriptive data were reported for nutrient intakes, and no comparisons were made with standards (e.g., RDA's).

A protective effect of high consumption of leafy green vegetables, carrots, tofu, fresh fruit, and fresh fish against specific types of lung cancer (adenocarcinoma and large cell cancer) was reported by Koo et al., (Ref. 76). Dietary data was obtained from a food frequency questionnaire. Consumption of fresh fruits was found to offer protection against squamous cell tumors of the lung. The data obtained in this study were analyzed by foods without specific analysis for single nutrients.

(ii) *Cancers of the colon and rectum (Table 7).* Food frequency questionnaires were used to obtain information on dietary patterns and risk of colorectal cancer. Freudenheim et al. (Ref. 77) reported that decreased risk of rectal cancer was associated with increased intake of carotenoids, vitamin C, and dietary fiber from vegetables. Graham et al. (Ref. 78) reported that there was a significantly reduced risk of colon cancer associated with high intakes of tomatoes, peppers, carrots, onions, and celery. LaVecchia et al. (Ref. 47) reported that the risk of both colon cancer and rectal cancer was inversely related to intake of green vegetables, tomatoes, melon, and coffee. There were also inverse relationships between risk and indices of carotenoid and vitamin C intake. Tuyns et al. (Ref. 79) found no association between risk for either colon cancer or rectal cancer and vitamin C intake (determined from food frequency questionnaires) in a case-control study in Belgium. West et al. (Ref. 80) also reported no association between risk of colon cancer and intake of vitamin C (determined from a food frequency questionnaire) in a case-control study of colon cancer patients and matched controls in Utah.

Several of these studies identified other dietary risk factors for colon and rectal cancers including increased risk with increasing intakes of calories and fat (Refs. 77 and 78) and consumption of rice and pasta.

A recent randomized clinical trial has been reported that describes a test of the effect of a vitamin C supplement on recurrence of polyps in the colon or rectum (Ref. 81). Subjects in this trial were randomized to receive 400 mg of vitamin E and C (96 subjects) or lactose (placebo; 89 subjects) for a 2-year period. Examination of subjects after 2 years revealed polyps in 41.4 percent of the vitamin-treated group and in 50.7 percent of the placebo group. The relative risk of polyps in the treatment group was not significantly different from that in the placebo group.

In a second intervention trial, De Cosse et al. (Ref. 82) studied the effects on rectal polyps of vitamin C plus vitamin E with and without grain fiber supplements. Fifty-eight patients with familial adenomatous polyposis who had total colectomy and ileorectal anastomosis 1 year before the study were randomized into groups receiving 2.2 grams (g) of fiber and placebo (low fiber), 2.2 g fiber plus 4 g vitamin C and 400 mg vitamin E per day (low fiber plus vitamins C and E), or 22.5 g fiber plus both vitamins per day (high fiber plus vitamins C and E). All groups also received a supplement containing vitamins C and A and several other vitamins and minerals. The results did not show any protective effect of the vitamin C and vitamin E supplement on the occurrence of rectal polyps.

(iii) *Breast cancer (Table 8).* The authors of a case-control study of women with breast cancer and hospital controls in Athens, Greece reported that there were no differences between cases and controls in intakes of vitamin C (determined from food frequency questionnaires) (Ref. 83). This study found no association between intake of vitamin C and risk of breast cancer.

In a case-control study in Italy, Toniolo et al. reported that there was no difference in vitamin C intake in 250 women with breast cancer and 499 women from the general population. Vitamin C intakes were determined from a modified food frequency questionnaire (Ref. 84).

Howe et al. performed a meta-analysis that included all case control studies relating diet and breast cancer that were completed by 1986. Dietary data were available from 9 of 12 studies. Estimates of intakes were made for the other three studies based upon responses to food frequency

questionnaires. A statistically significant inverse association between vitamin C and breast cancer was reported (Ref. 85). Beta-carotene, fiber, and carotenoids (other markers for consumption of fruits and vegetables) also showed an inverse relationship with risk of breast cancer (Ref. 85).

(iv) *Prostate cancer (Table 9).* Kolonel et al. (Ref. 86) found no associations between risk of prostate cancer and total of food sources of vitamin C in a case-control study involving 452 cases of prostatic cancer and 899 age-matched controls. Dietary information was obtained from a food frequency questionnaire. Increased risk was found to be associated with intake of saturated fat and zinc (Ref. 86).

In two case control studies, Ohno (Ref. 43) and Oishi (Ref. 42) reported that intake of vitamin C from foods was not significantly associated with risk of prostate cancer.

(v) *Pancreatic cancer (Table 10).* LaVecchia et al. (Ref. 48) reported a statistically significant decreased risk of pancreatic cancer with increased intake of fresh fruits. A similar inverse relationship between intake of fish and oil and risk of pancreatic cancer was also reported in this study. This case-control study, carried out in Italy, involved 247 patients with pancreatic cancer and 1,089 age and sex-matched hospital-based controls with acute nondigestive, nonneoplastic disease. Subjects were interviewed to obtain data on socioeconomic status, tobacco and alcohol use, coffee consumption, medical history, and dietary intake of 14 "indicator" foods. No assessment of intake of individual nutrients was made in this study.

Mills et al. (Ref. 87) investigated dietary habits and risk of pancreatic cancer in about 34,000 non-Hispanic Seventh Day Adventists in California. All subjects completed a life-style questionnaire. A significant protective relationship between consumption of vegetable protein products, beans, lentils, or peas, and dried fruits and fatal pancreatic cancer was reported (Ref. 87). No relationship was found between risk and intake of other fresh fruit, canned or frozen fruit, fresh citrus fruit, green salads, or cooked green vegetables (Ref. 87). No data on individual nutrients were provided in this study.

Falk et al. (Ref. 88) reported a significant inverse relationship between consumption of fresh fruit and fruit juice and pancreatic cancer. The case-control study involved 363 cases of pancreatic cancer and 1,234 hospital-based controls matched on hospital of admittance, race, sex, and age. A food frequency questionnaire was used to obtain dietary information. No descriptive nutrient data was reported, and there were no comparisons of dietary intakes to reference standards (e.g., RDA's).

(vi) *Stomach cancer (Table 11).* You et al. (Ref. 89) reported the results of a case-control study in China involving 564 subjects with gastric cancer and 1,131 population-based control subjects. An undefined number of years had elapsed between the "reference period" and the interviews which served to collect data about demographics, medical histories, occupations, smoking histories, and diet. There was a decline in risk of gastric cancer with increased consumption of beta-carotene, vitamin C, and calcium which was associated with high intakes of fresh fruits and vegetables (Ref. 89).

Kono et al. (Ref. 90) reported an inverse relationship between intake of fruits and risk of gastric cancer in a case-control study involving 139 cases of newly diagnosed gastric cancer, 2,574 hospital-based control subjects, and 278 randomly-selected community control subjects in Japan. Gastric cancer patients and hospital-based control subjects were interviewed before diagnosis. A questionnaire was used to obtain information on dietary habits and on consumption of specific food items. The data showed a protective effect against stomach cancer associated with increased frequency of consumption of fruits, mandarin oranges, and green tea (Ref. 90). Attribution of effects to vitamin C could not be made because of the design of this study. Dietary components other than vitamin C, or in addition to vitamin C, could have been responsible for the protective effects.

Buiatti et al. (Ref. 91) studied 1,016 cases of gastric cancer and 1,159 control subjects matched for age and sex. Data regarding demographics, socio-economic status, occupational histories, smoking, medical histories, and diet were obtained from an interview. Intakes of specific nutrients were calculated from responses to a food frequency questionnaire. Buiatti et al. (Ref. 91) reported that decreased risk of gastric cancer was associated with increased consumption of citrus fruits, other fresh fruits, and raw vegetables. Results of further evaluation of the data (Ref. 92) suggested that the protective effects of fresh fruits, fresh vegetables, and olive oil may be associated with vitamins C and E present in these foods. Estimates of the intakes of nitrates and nitrites were calculated for several geographic areas studied, and results indicated an increasing risk of stomach cancer with increasing consumption of nitrates and nitrites. Risk decreased with increasing intakes of vitamin C and vitamin E (Ref. 92).

Chyou et al. (Ref. 93) initiated a case-cohort study of about 8,000 Hawaiian men of Japanese ancestry during 1965 to 1968. Stomach cancer was diagnosed in 111 men during the following 18 years. Dietary data obtained from these subjects and from 361 cancer-free men revealed that consumption of all types of vegetables was protective against stomach cancer (Ref. 93). Increased intake of fruits was also protective against stomach cancer, but this trend was weakened when cigarette smoking was taken into account (Ref. 93).

Burr et al. (Ref. 94) carried out a cross-sectional study in two towns in England and Wales that had differing death rates from stomach cancer. Burr et al. (Ref. 94) reported that plasma ascorbate levels and fruit intakes were significantly higher in individuals in the low-risk town than in individuals in the high-risk town. No direct relationship between plasma ascorbate levels and the presence of severe atrophic gastritis was found. No dietary data were presented in this study, and the nature of a food frequency questionnaire was not described. There were significant socio-economic differences between the towns, and subjects were not matched for smoking, health histories, or demographics. There were also significant differences in incidence of gastric surgery and severe atrophic gastritis between towns.

Stahelin et al. (1989) (Ref. 61) reported on a prospective cohort study of 2,975 men, 17 of whom subsequently developed stomach cancer. The authors reported that after adjusting for smoking, plasma vitamin C was significantly lower in cases of stomach cancer than in control men. This study relied on a point sample analysis and provided no dietary intake data.

(vii) *Cancers of the head and neck (Table 12).* Franco et al. (Ref. 95) investigated risk factors for oral cancer in a case-control study in Brazil. Dietary information and health and demographic characteristics were obtained from interviews with 232 patients with oral cancer and 464 hospitalized non-cancer subjects. The strongest risk factors identified in this study were use of tobacco and alcohol. A decrease in risk was observed with more frequent consumption of citrus fruits. It was not possible to calculate intakes of vitamin C in this study.

Results of a population-based case-control study on association of dietary factors with oral cancers were reported by McLaughlin et al. (Ref. 96). Frequency of consumption of food items was

obtained by questionnaire from 871 patients with oral cancer and 979 control subjects. Protective effects were reported with increased consumption of citrus fruits. The study was not designed to specifically address a possible role of vitamin C in reduction in risk of oral cancer.

(viii) *Cancers of the cervix and ovary (Table 13).* Brock, et al. (Ref. 62) reported that when considered together, vitamin C, fruit juices, and plasma beta-carotene showed a significant protective effect against cervical cancer. Dietary information was obtained from a food frequency questionnaire. Cases in this study were not matched on sexual habits, smoking, or use of oral contraceptives. Plasma levels of ascorbic acid were not determined.

Shu et al. (Ref. 97), Slattery et al. (Ref. 44), and Ziegler et al. (Ref. 98) reported no effects of dietary vitamin C on risk of ovarian cancer or cervical cancer. Dietary information in these studies was obtained from a food frequency questionnaire. Significantly increased risk of ovarian cancer was associated with intake of total and saturated fat (Ref. 97). Verreault et al. (Ref. 63) found a decreased risk of cervical cancer associated with high intakes of vitamin C. After adjustment of data for other known risk factors, increased intakes of dark green or yellow vegetables and fruit juices were associated with significantly reduced risk (Ref. 63).

(ix) *Other studies (Table 14).* Results of a case-control study of bladder cancer patients and hospital controls in Italy showed that risk of bladder cancer was not related to intake of vitamin C (Ref. 49).

b. *Studies on vitamin C in relation to carcinogen-forming reactions.* Ascorbic acid is an effective antioxidant in human plasma (Ref. 99). It is also secreted into gastric juice in concentrations that often exceed those in plasma (Ref. 100).

Patients with chronic gastritis have lower concentrations of vitamin C in gastric juice than do those without chronic gastritis, and those with lower gastric juice vitamin C levels are more likely to develop stomach cancer (Ref. 101). Concentrations of vitamin C in both gastric juice and in plasma are lower in patients with chronic atropic gastritis who also have intestinal metaplasia than in chronic atropic gastritis patients without intestinal metaplasia (Ref. 101). The patients with intestinal metaplasia also had higher plasma nitrite levels than those without the disorder.

Biochemical and experimental animal evidence is compelling that vitamin C can inhibit nitrosation reactions, and thereby act as an effective anticarcinogen under experimental conditions (Ref. 25). Most nitrosamines, including diethylnitrosamine, are animal carcinogens that are mutagenic through reactions with DNA (Ref. 102). Carcinogenic nitrosamines can be formed in vivo (Ref. 103). In vivo synthesis of nitroso compounds may be the greatest source of exposure for the general population (Ref. 2). Ascorbic acid in gastric juice may be an effective inhibitor of gastric nitrosation reactions.

N-nitrosoproline is one of the few apparently noncarcinogenic N-nitrosamines. As such, it is considered a good model compound for studying nitrosation reactions in humans. A method to quantify in vivo nitrosation in humans using sequential oral doses of nitrate and proline and measuring excretion of N-nitrosoproline has been reported (Ref. 104). This technique has been used to show that large doses of ascorbic acid can inhibit formation of nitrosoproline (Refs. 132 and 133). Recent studies in humans by Leaf et al. (Ref. 27) showed that in vivo nitrosation is very complex and may involve many factors in addition to nitrate exposure. These findings indicate that ascorbic acid is capable of inhibiting in vivo synthesis of putative human carcinogens. It is not clear from these studies what dosage of vitamin C is necessary to achieve biologically significant inhibition of nitrosamine synthesis at various intakes of nitrite and nitrate, or whether the food supply already supplies that amount of vitamin C. It also is not clear what degree of such inhibition would be necessary to generate a meaningful decrease in cancer risk.

The relevance of ascorbic acid inhibition of nitrosation and possibly other reactions to human cancer risk may be more directly addressed by studies of dietary relationships to fecal genotoxicity (Ref. 105). The basic assumption is that at least a large fraction of total cancer is produced by genotoxic (i.e., mutagenic) mechanisms, an assumption that is well documented (Refs. 4a, 22, 24). Consumption of supplements containing ascorbic acid decreases fecal mutagenicity (Ref. 106), but this effect may not be completely attributable to inhibition of nitrosation reactions. Ascorbic acid inhibits nitrosation reactions but also decreases stool concentrations of mutagenic products, fecapentenes, which are derived from lipids (Ref. 105).

c. *Animal studies.* Data from research links vitamin C to lowered risk of cancer in animals under a variety of experimental conditions (Refs. 107 and 108). In animals and in in vitro systems, both vitamin C and vitamin E can inhibit the formation of carcinogenic nitrosamines. Most nitrosamines are carcinogenic in one or more assay systems, but they are most accurately described as procarcinogens, because biological activation is required to convert them to the reactive ultimate carcinogen.

Because of the antioxidant nature of vitamin C, it is reasonable to hypothesize that this vitamin may prevent activation of procarcinogens to the ultimate carcinogen, or, if activation occurs, vitamin C may react with and deactivate the ultimate carcinogen. Animal studies that examined the effect of vitamin C on nitrosamine synthesis and subsequent carcinogenesis as a result of exposure to the nitrosamine precursors, nitrite and a monoamine, provide strong evidence that vitamin C can lower risk of cancer through this mechanism (Refs. 25 and 134). Other studies with animals that examined the effect of vitamin C on other types of chemically-induced cancers have not produced consistent results (Ref. 108).

2. Safety Issues

The Surgeon General's report stated that amounts of vitamin C in excess of the RDA's may cause rare adverse effects including gastrointestinal disturbances, iron overload in susceptible individuals, altered metabolism of certain drugs, precipitation of calcium oxalate kidney stones, altered absorption (both positive and negative) of several minerals, and interference with clinical laboratory tests (Ref. 4a).

3. Conclusions

The majority of the studies summarized above on the association between vitamin C and cancer are epidemiologic studies. These studies depended on dietary data gathered with the use of food frequency questionnaires. In some studies, retrospective dietary information was collected to provide insight into associations between nutrient intakes and cancer at specific sites. However, in most studies, collection of direct data on actual intakes of specific nutrients was not possible.

In a number of the studies, protective effects against cancer at specific sites were observed with increased frequency of consumption of such foods as vegetables, green leafy vegetables, fresh fruits, citrus fruits, and fruit juices. In most studies, it was not possible to determine whether a protective effect was due to the presence of vitamin C, beta-carotene, other nutrients, or

combined effects of both vitamins and other dietary factors such as fiber. In addition, levels of ascorbic acid were rarely measured in the studies reviewed.

The evidence for associations between consumption of foods high in vitamin C and reduced risk of cancer appears to differ markedly by site. Consumption of vitamin C-rich foods appears to be most frequently associated with lower risk of cancer of different parts of the gastrointestinal tract. Intake of vitamin C-rich foods does not appear to be associated with risk of breast cancer. Recent data provide mixed or negative results with regard to vitamin C-rich foods and cancer of the colon/rectum, pancreas, lung, prostate, and cervix/ovary.

Overall, the recent human studies provide evidence that consumption of certain foods notably many fruits and vegetables (which contain higher levels of vitamin C and other nutrients) may reduce the risk of certain cancers, notably those of the stomach and other parts of the gastrointestinal tract. These studies do not clearly demonstrate that the effects are the result of the vitamin C per se.

D. Tentative Decision To Deny Health Claims Relating Ingestion of Vitamin C to Reduced Risk of Cancer

The agency is proposing not to authorize the use on foods, including conventional foods and dietary supplements, of claims relating to associations between ingestion of vitamin C and reduced risk of cancer.

There is strong epidemiologic evidence that consumption of certain foods, notably many fruits and vegetables (which tend to contain higher levels of vitamin C), reduce the risk of cancers at some sites, notably the stomach and other parts of the gastrointestinal tract. It is not possible to determine from the currently available data whether the reduced risks of cancers at specific sites are caused by the vitamin C content of foods or by other components that are also present.

The agency's tentative conclusion is consistent with information and conclusions found in Federal Government and other authoritative documents. The Surgeon General's report on "Nutrition and Health" (Ref. 4a) concluded in 1988 that no wholly consistent picture of the role of vitamin C in human cancer had been defined. The NAS "Diet and Health" report (Ref. 2) concluded that diets high in plant foods (fruits, vegetables, legumes, and whole-grain cereals) are associated with a lower incidence of coronary heart disease and cancers of the lung, colon, and stomach. The NAS report observed that such diets are low in total fat and rich in complex carbohydrates and certain vitamins and minerals. The NAS report concluded that epidemiologic studies suggest that vitamin C-containing foods such as citrus fruits and vegetables may offer protection against stomach cancer, and that animal studies indicate that vitamin C itself can protect against nitrosamine-induced stomach cancer. Evidence linking vitamin C, or foods containing vitamin C, to cancer at other sites is more limited and less consistent.

The scientific data that have become publicly available since the publication of authoritative documents of the Federal Government and others provide no substantive evidence that would alter the conclusions found in these reports.

FDA has tentatively determined, based on the totality of publicly available scientific evidence regarding an association between vitamin C and cancer, that there is not significant scientific agreement, among experts qualified by scientific training and expertise to evaluate such claims, that the claim associating vitamin C to the risk of cancer is supported by such evidence. Therefore, the agency is proposing to deny the use on foods of claims relating to associations between ingestion of vitamin C and reduction in risk of cancer.

The agency recognizes that the evidence is strong that consumption of fruits and vegetables, good sources of vitamin C, is associated with lowered risk of cancer at a number of sites, especially of the stomach. However, the agency believes that the data are not sufficiently convincing that vitamin C itself is responsible for this epidemiological association, even though the inhibition of nitrosation reactions in human subjects by vitamin C is established. Further, even if the evidence for a cause-and-effect relationship of vitamin C intake with lowered risk of stomach cancer was assumed to be adequate, the agency finds the data to be insufficient to determine the quantity of vitamin C needed to produce the effect. If such data were available, it would be necessary for the agency to determine whether the food supply already provides enough vitamin C to produce that effect.

In summary, the agency requests submission of data which directly bear on: (1) Whether vitamin C itself, rather than some other component of food, decreases the risk of cancer in humans, and (2) the range of intake in which vitamin C produces this effect.

IV. Review of Scientific Evidence: Vitamin E

A. Federal Government Documents

In 1988, the "Surgeon General's Report on Nutrition and Health" (Ref. 4a) summarized the evidence on the role of vitamin E and cancer. The Surgeon General's Report stated that in human studies, no relationship had been found between vitamin E levels and the risk of cancer when the incidence rates of all cancer sites were combined. In addition, the report proposed that because vitamin E is an antioxidant, the protective role tentatively assigned to both the carotenoids and vitamin C may be hypothesized to apply, but that present data are too limited to draw conclusions.

B. Other Authoritative Documents

The 1989 NAS report on "Diet and Health" (Ref. 2) concluded that some investigators have postulated that vitamin E may block the initiation or promotion of cancer, but the committee judged the evidence to be too limited to draw conclusions.

The Life Sciences Research Office (Ref. 38) in a detailed review of recent observational and intervention studies on vitamin E and cancer concluded that available information still is not sufficient to support definite conclusions concerning vitamin E intake and the risk of human cancer. The report stated that more studies, especially well designed intervention trials and observational studies, are needed.

C. Review of Scientific Literature

1. Introduction

The agency reviewed the available scientific evidence on vitamin E and cancer provided by epidemiological studies (prospective and retrospective) and clinical studies. The data reviewed were evaluated according to specific criteria. Studies that involved healthy matched controls (e.g., age and sex), that were controlled for confounders, such as smoking, used validated dietary assessment instruments, appropriate storage conditions for test samples, and adequate sample size were given the most weight. When the possibility could not be excluded that the observed association was mainly a result of the disease altering indicators of vitamin E status, or resulted from an effect of another substance in the food, the study was given less weight.

2. Primary Studies in Humans

Prospective studies are considered first in this section, followed by retrospective studies and clinical trials.

The prospective studies were generally conducted in case-control designs (Table 15). In most of the prospective studies, plasma/serum vitamin E and subsequent cancer development was studied.

The prospective studies generally concentrated on all sites of cancer, hormone-related cancers, and cancers of the lung and gastrointestinal tract (Table 15). Studies that concentrated on all cancer sites generally observed an inverse association between serum vitamin E and subsequent cancer, (Refs. 109 through 113). In a 12-year cancer mortality followup of one of the studies, no significant association was found between low plasma vitamin E levels and all cancer sites combined (Ref. 61). Comstock et al. (Ref. 114) reported a significant dose response trend between serum vitamin E and lung cancer. However, other workers, reported no significant association of serum vitamin E and the subsequent development of lung cancer (Ref. 57 and 109).

Two studies using two different population groups observed an association between vitamin E and gastrointestinal cancers (Refs. 109 and 113). A 12-year followup study (Refs. 60 and 61) conducted using one of the same population groups did not confirm the association between vitamin E and gastrointestinal cancer. In another prospective study (Ref. 115) reported an apparent association between low serum levels of vitamin E and reduced risk of pancreatic cancer. However, the difference was not statistically significant. The number of cases was small, and the storage time for the serum was very long prior to analysis, making the reliability of these data doubtful. Schober et al. (Ref. 116) studied the same population group and found no association between vitamin E and colon cancer.

No relationship was found between vitamin E levels and the subsequent development of breast cancer (Refs. 110, 113, 114, and 117). In an earlier study, Wald et al. (Ref. 55) reported a significant inverse association between vitamin E and breast cancer. The number of breast cancer cases in these studies was generally very small.

The maximum followup time in these prospective studies generally ranged from 7 to 8 years (Refs. 109 and 117) to 9 to 13 years (Refs. 60, 61, and 114). In all the studies that FDA examined, except the Basel study (Refs. 60, 61, and 109), vitamin E determinations were based on stored frozen serum/plasma samples collected in baseline examination and thawed for analyses at the end of the followup. It has been reported that the length and storage conditions of the test samples may decrease the levels of vitamin E in serum/plasma, and therefore make the data unreliable (Ref. 57).

Retrospective studies on vitamin E and cancer are shown in (Table 16). Breast cancer has been the subject of several case-control studies (Refs. 84, 118, and 119). With one exception (Ref. 119), the studies generally found no significant association between breast cancer and vitamin E levels in the serum or vitamin E intake. Gerber (Ref. 119) found that plasma vitamin E was significantly higher in breast cancer cases than hospital controls. However, the vitamin E intake data did not support this observation.

Another study observed lower serum vitamin E levels in lung cancer patients (Ref. 120). Adjustment of the vitamin E levels for serum cholesterol reduced the difference between lung cancer cases and controls. The experimental groups used in this study were not matched for smoking history.

Two studies conducted in other countries reported a significant inverse association of vitamin E with either gastric or digestive cancers (Refs. 92 and 121). One author (Ref. 92) suggested that the observed decrease in serum vitamin E in digestive cancer cases may be a consequence of nutritional inadequacies. Verreault (Ref. 63) examined the association of vitamin E using invasive cervical cancer cases and population controls. High intakes of vitamin E were associated with lower cancer risk. Another study reported (Ref. 122) a significant trend of lower mean serum vitamin E levels in association with cervical intraepithelial neoplasia. The sample size was small and the authors pointed out the need to examine interactive factors such as sexual behavior and smoking.

Two studies (Refs. 123 and 124) observed no significant association between vitamin E and specific cancer sites (rectal and larynx). Stryker (Ref. 125) observed that vitamin E intake, but not serum vitamin E, displayed a significant trend of decreasing risk of malignant melanoma. The vitamin E intake in the studies cited were based on retrospective dietary data, and the accuracy of the data is therefore difficult to assess. In addition, the evidence based on dietary intake data is often confounded by other nutrients that may also be associated with the risk of cancer.

Intervention trials (clinical) involving vitamin E and cancer are limited. One recent clinical trial examined the effect of vitamins C and E in the reduction of the risk of recurrence of colorectal polyps (Ref. 81). Another study (Ref. 82) reported a chemoprevention trial on large bowel neoplasia using either supplements of ascorbic acid plus vitamin E alone or with a grain fiber supplement. The combined use of vitamins prevented an analysis of the independent effect of vitamin E or interactions with vitamin C.

3. Supporting Data From Animal Studies

Animal studies on the effect of vitamin E (usually alpha-tocopherol) on carcinogenesis have yielded conflicting results. Several recent reports (Refs. 5b, 34, and 126) have reviewed the experimental evidence on the effects of vitamin E in cancer prevention. Most studies have dealt mainly with chemically induced cancers. Birt (Ref. 126) summarized the results of 14 animal studies involving the use of 3 different species of animals and 4 preformed carcinogens. Some of the studies observed inhibition of two-stage skin, oral and forestomach tumorigenesis. Other studies showed enhancement, no effect, or inhibition of rat mammary gland and rat and mouse carcinogenesis.

Mergens and Bhagavan (Ref. 34) and Merrill et al. (Ref. 5b) summarized animal studies on the inhibition of carcinogenesis by alpha-tocopherol. These reviews show that results from animal studies were frequently positive, however, many studies show no effect or are negative. Animal studies have shown that, under certain conditions, vitamin E has been shown to inhibit the formation of carcinogenic nitrosamines (Refs. 5b and 34).

4. Safety Issues

The NRC, in "Diet and Health" (Ref. 2), summarized two studies (Refs. 127 and 129) and a review article on the safety of oral intake of vitamin E. The studies suggested that large doses of vitamin E are relatively nontoxic. The review article (Ref. 130) cited by the Council extensively reviewed overall safety issues of vitamin E. The authors reported that in human studies conducted with double blind protocols and in large population studies, oral vitamin E supplementation resulted in few side effects even at doses as high as 3,200 mg per day. They concluded that most of the reported side effects: breast soreness, altered creatinine excretion, emotional disorders, fatigue, gastrointestinal stress, thrombophlebitis, and decreased thyroid levels, have come from uncontrolled studies or case reports (Ref. 130). However, in persons with vitamin K deficiency produced either by malabsorption or anticoagulant therapy, vitamin E

supplementation can exacerbate the coagulation defect.

In the 1989 edition of "Recommended Dietary Allowances," the NRC (Ref. 14) stated that compared with other fat-soluble vitamins, vitamin E is relatively nontoxic when taken by mouth.

D. Conclusions

Some recent prospective studies provide suggestive evidence of an association of lower plasma/serum vitamin E levels with increased risk of cancer (Ref. 113). However, the different population groups studied were limited and results from some followup studies were inconsistent. Clarification of the role of vitamin E in the reduction of cancer risk would be greatly enhanced by studies that also examine the quantitative dietary intake of vitamin E. Many of the studies were based on relatively small numbers of cancer cases, used test samples that had been stored for long periods of time prior to analysis, or relied on retrospective food frequency interviews. These factors may contribute to unreliable interpretations of the results.

While some of the recent retrospective studies have provided suggestive evidence that low vitamin E intake or low plasma/serum levels of vitamin E may be associated with the increased risk of some cancer, other studies have not. Many of the studies have study design flaws (e.g., inappropriate controls, small sample size). Too few clinical trials have been conducted on the association of vitamin E status and the risk of cancer to clearly implicate vitamin E.

E. Tentative Decision To Deny a Health Claim Relating to Ingestion of Vitamin E to the Risk of Cancer

FDA considered conclusions reached by Federal Government documents, and other authoritative documents, a review of the topic by Life Sciences Research Office of the Federation of American Societies for Experimental Biology, and all comments received in response to a **Federal Register** notice of a request for scientific data and information. The agency also reviewed recent publicly available scientific data on the association between vitamin E and cancer.

In 1988, the *Surgeon Generals' Report on Nutrition and Health* (Ref. 4a) documented and reviewed available literature on the possible relationship of vitamin E and cancer. The Surgeon General did not find the evidence strong enough to justify a recommendation to the general public on vitamin E and cancer. However, the report proposed that the protective role tentatively assigned to both carotenoids and vitamin C may apply to vitamin E. The NRC Committee on Diet and Health (Ref. 2) also reviewed current literature on the topic. The committee's report concluded that the scientific evidence was insufficient to draw conclusions about the relationship between vitamin E and cancer.

Several followup studies and new studies have appeared in the literature since the above reports (see Tables 1 and 2). Recent epidemiological studies exploring the association of blood levels of vitamin E as well as dietary vitamin E intake with the risk of cancer are contradictory. Some studies support an inverse association of blood levels of vitamin E/vitamin E intakes with the risk of certain cancers, while others do not.

FDA has tentatively determined, based on the totality of publicly available scientific evidence regarding an association between vitamin E and cancer, that there is not significant scientific agreement among experts qualified by scientific training and expertise to evaluate such claims that the claim associating vitamin E to the risk of cancer is supported by such evidence.

The agency recognizes that consumption of food sources of vitamin E is frequently, but not consistently, associated with lowered risk of cancer at a number of sites. However, the agency believes that the data do not sufficiently demonstrate that vitamin E itself is responsible for this association, or permit identification of what other factors may produce or prevent the effect. Further, even if the evidence for a cause-and-effect relationship of vitamin E intake with lowered risk of cancer was assumed to be adequate, the agency finds the data to be insufficient to determine the quantity of vitamin E needed to produce the effect. If such data were available, the agency would have to determine whether the food supply already provides that amount of vitamin E.

In summary, the agency requests submission of data which directly bear on: (1) Whether vitamin E itself, rather than some other component of food, decreases the risk of cancer in humans, (2) the range of intake in which vitamin E produces this effect, and (3) factors which may limit any vitamin E effect.

V. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(1) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VI. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VII. Comments

Interested persons may, on or before February 25, 1992 submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in the brackets in the heading of this document. Received comments may be seen in the office between 9 a.m. and 4 p.m., Monday through Friday.

VIII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

List of Subjects in 21 CFR Part 101

Food Labeling, Reporting and recordkeeping requirements.

PART 101—FOOD LABELING

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.71 is amended by adding new paragraph (d) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(d) Antioxidant vitamins and cancer (insert cite and date of publication in the **Federal Register** of the final rule).

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

TABLE 1.—ANTIOXIDANT VITAMINS AND CANCER: RETROSPECTIVE STUDIES OF DIETARY AND SERUM CAROTENOIDS AND CANCER

Authors and year	Source exposure	Study population	Cancer site	Cases/controls	Results	Assessment of study
LeMerchand, et al., 1991 (Ref. 41).	Beta-carotene, reevaluation of dietary data.	Oahu, Hawaii, multiethnic men.	Prostate	452/899	Reexamined data eliminating papaya and found no association of beta-carotene with prostate cancer risk in men 70 years.	Positive association between papaya and prostate cancer was observed in men >70.
LeMerchand, et al., 1989 (Ref. 39).	Beta-carotene, other provitamin A carotenes, vegetables and fruits.	Oahu, Hawaii, multiethnic men and women.	Lung	230/597	Higher intakes of foods containing beta-carotene associated with lower lung cancer risks.	Stronger inverse association occurred with all vegetables, dark green and cruciferous vegetables, and tomatoes than with beta-carotene.
Bond, et al., 1987 (Ref. 40).	Dietary carotenoids	Chemical company employees, Texas, men.	Lung	308/616	Higher intakes of foods with high carotenoid index were associated with lower lung cancer risks.	The reported reliance on surrogate sources of dietary information and the relatively long retrospective period are flaws which detract from the results.
Kune, et al., 1987 (Ref. 46).	Vegetables	Case-control in Melbourne, Australia, men and women.	Colon, rectum	715	Higher intakes of beta-carotene, total vegetables, fiber and vitamin C were related to lowered risks.	Also some protection occurred with supplement usage. Retrospective period of long duration.
Coggon, et al., 1989 (Ref. 45).	Fruits and vegetables	Case-control, England.	Stomach	95/190	Intakes of fruit and salad vegetables inversely associated with risk.	Did not report on supplement alcohol, smoking or health history. Difficult to draw conclusions on effects due to beta-carotene.
LaVecchia, et al., 1988 (Ref. 47).	Fruits and vegetables	Case-control, Italy	Colon, rectum	339, 236, 778, controls.	Risk of both cancers inversely related to carotenoid and vitamin C indices.	Reported no information on supplement usage or community-based controls.
Smith and Waller, 1991 (Ref. 50).	Beta-carotene	Wellington, New Zealand cases, controls and their families.	Lung, stomach, esophagus, small bowel, cervix, uterus.	618/675	Plasma beta-carotene was lower in cancer patients and their relatives compared with control patients and their relatives.	A unique study of cancer and control patients and their families.
Ohno, et al., 1988 (Ref. 43).	Beta-carotene and vitamin A.	Japan case-control	Prostate benign prostatic hyperplasia	100/100	Intakes of beta-carotene and vitamin A inversely related to prostate cancer.	Report did not provide data on smoking or supplement usage. The time between the disease reported and dietary intake data is of long duration.

TABLE 2.—ANTIOXIDANT VITAMINS AND CANCER: PROSPECTIVE STUDIES OF DIETARY CAROTENOIDS AND CANCER

Authors and year	Source or exposure	Study population	Cancer site	Cases/controls	Results	Assessment of study
Paganini-Hill, et al., 1987 (2) (Ref. 54).	Carotenoids	5-yr cohort study, California retirement community, men and women.	All cancer, breast, bladder, lung, colon.	638, 123, 58, 55, 110.	No association found between beta-carotene consumption and subsequent development of cancer.	Study conducted in a retirement community where intakes of all nutrients are already very high. No specifics on supplement use was reported. The agreement between the questionnaire used in the first and second followup was reported to be only 50% reducing reliability of study.
Lee, et al., 1991 (Ref. 52).	Beta-carotene, soya, products and PUFA [1].	Chinese women of Singapore.	Breast	200/420	Inverse association with higher intakes of beta-carotene and other foods. Cannot separate effects due to beta-carotene versus those due to soya foods and poly-unsaturated fatty acids.	Authors suggested that soya products which are rich in phytoestrogens and beta-carotene may have influenced results in premenopausal women.
Harris, et al., 1991 (Ref. 51).	Beta-carotene	Men with cancer	Lung, other epithelia cancer controls.	96, 75, 97	Stronger inverse association with beta-carotene intake and cancers than with carotene-rich vegetables. Serum carotene correlated with dietary carotenes.	Age-matched controls were inpatients with nonmalignancy. Relatively small sample population.
Rohan, et al., 1988 (Ref. 53).	Beta-carotene foods	Australia. Case-control women.	Breast	451/451 (community-based controls).	Risk in premenopausal women decreased with increased intake of beta-carotene foods. In postmenopausal women risk was highest in the second lowest quintile of consumption.	Reported no data on supplement use. The standardized questionnaire used in collecting food intake data did not make use of food models or photographs in estimating portion sizes.

[1] Polyunsaturated fatty acids.

TABLE 3.—ANTIOXIDANT VITAMINS AND CANCER: PROSPECTIVE STUDIES OF SERUM OR PLASMA CAROTENOIDS AND CANCER

Authors/year (#)	Source/exposure	Study population	Cancer site	Cases/controls	Results	Assessment of study
Wald, et al., 1988 (Ref. 56).	Beta-carotene	BUPA [1] Medical Center, London, United Kingdom, men.	All cancer, lung, colorectal, CNS, bladder, stomach.	271/533, 50/99, 30/59, 17/34, 15/29, 13/26.	Reduced serum beta-carotene levels in all, lung, and stomach cancers and nonsignificant reduced levels in colorectal, CNS,[2] and bladder cancers.	No information reported on median storage times between sample collection and cancer diagnosis or death.
Connett, et al., 1989 (Ref. 58).	Total carotenes and beta-carotene.	22 MRFIT [3] centers, men.	All cancer, lung, gastro-intestinal, colon.	156/311, 66/131, 28/56, 41/28.	Higher serum levels were related to lower rates of lung cancer and trends towards relationship to reduced rates of gastrointestinal cancer.	One limitation is that this study used a single 24-hour dietary recall for collecting dietary information, therefore, the trend toward lower intake of beta-carotene in lung cancer cases may have assumed greater significance had more extensive dietary data been collected.
Stahelin, et al., 1991 (Ref. 60).	Beta-carotene	Chemical Company employees, Basel, Switzerland, men.	Bronchus, stomach, colo-rectal.	68, 20, 17	Overall cancer mortality was associated with low plasma carotene, but specifically that from bronchus and stomach cancer.	Well-designed study with good controls. However, no dietary data or supplement usage reported.

TABLE 3.—ANTIOXIDANT VITAMINS AND CANCER: PROSPECTIVE STUDIES OF SERUM OR PLASMA CAROTENOIDS AND CANCER—Continued

Authors/year (#)	Source/exposure	Study population	Cancer site	Cases/controls	Results	Assessment of study
Burney, et al., 1989 (Ref. 115).	Beta-carotene, lycopene.	Washington County, Maryland men and women.	Pancreas	22/44	Lower serum lycopene, not beta-carotene was associated with higher mortality from pancreatic cancer.	Storage of serum samples was of long duration and there was no report of dietary intake or supplement usage.
Knekt, et al., 1990 (Ref. 142).	Beta-carotene	Finland, cohort	All cancer sites	766/1419	Inverse relationship between mean serum beta-carotene levels and smoking and cancer risk after adjustment for smoking.	Blood storage time was of long duration. No dietary intake or supplement usage data were reported.

[1] British United Provident Association.
[2] Central nervous system.
[3] Multiple risk factor intervention trial.

TABLE 4.—ANTIOXIDANT VITAMINS AND CANCER: PREMALIGNANCY AND BETA-CAROTENE

Authors and year	Source/exposure	Study population	Cancer site	Cases/controls	Results	Assessment of study
VanEenwyk, et al., 1991 (Ref. 65).	Dietary and Serum Beta-carotene.	Women	Cervical Intra-epithelial, neoplasia (CIN).	102/102	Higher intakes and serum levels of lycopene were associated with lower frequency of CIN.	Combined dietary and serum data with biopsy data plus the control of confounding variables makes this a convincing study.
De Vet, et al., 1991 (Ref. 67).	Supplemental beta-carotene 10 mg per day.	Women	Cervical dysplasia	137/141	Inconclusive	Duration of supplementation too short and sample size was too small to allow conclusions to be drawn.
Palan, et al., 1991 (Ref. 66).	Plasma beta-carotene.	Cross-sectional study, women.	Uterine cervic dysplasia.	116	Reduced plasma beta-carotene and vitamin E associated with increased cervix dysplasia and cancer.	Cross-sectional study without proper control groups. However, study considered for smoking behavior as a confounding variable.
Brock, et al., 1988 (Ref. 62).	Dietary and plasma beta-carotene.	Patients and community-based matched controls.	Cervical cancer *in situ*.	117/196	Higher dietary and plasma beta-carotene were inversely associated with cancer.	Matched cases with controls for smoking and other confounding variables. Good overall design.
Verreault, et al., 1989 (Ref. 63).	Beta-carotene and dark green and yellow vegetables.	Case-control, Washington.	Cervical cancer	189/227	Higher intakes of carotenes related to lower risks of squamous cell cancers.	Limitations are the long duration between interview and reference period and long retrospective period.
Basu, et al., 1991 (Ref. 64).	Plasma beta-carotene.	Women patients with diagnosed cervix abnormality.	Cervical dysplasia	75	Reduced levels of beta-carotene in smokers and nonsmokers with cervix dysplasia.	No report as to whether or not reduced plasma beta-carotene is due to the disease state.

TABLE 5.—ANTIOXIDANT VITAMINS AND CANCER: CHEMOPREVENTION INTERVENTION TRIALS WITH BETA-CAROTENE

Study site/investigator	Target site/organ	Target/risk group	Supplementary agent	Results	Assessment of study
Greenberg, et al., 1990, Dartmouth, UCLA,[1] U Minn,[2] UC-San Francisco [3] (Ref. 20).	Skin	Biopsy proved nonmelanoma basal-cell or squamous-cell carcinoma.	Beta-carotene, 50 mg per day.	No difference between cases and control groups in new cases of nonmelanoma skin cancer.	Well-designed double-blind intervention trial of 5-year duration.
Buring and Hennekens, 1990, Harvard School of Public Health (Ref. 140).	All cancer sites	American Physicians	Beta-carotene, aspirin	Continuing	N/A.
Stich, et al., 1988 (Ref. 68).	Oral leuplakias and micronucleated cells.	Betel nut/tobacco chewers.	Beta-carotene, 180 mg/week; Vitamin A, 100,000 IU [4]/week.	Inhibition of micronucleated cells after 3 months. Regression of leukoplakias after 6 months..	Authors suggested considerable variation in tissue levels of beta-carotene may affect study outcome.

[3] University of California at Los Angeles.
[4] International units.

TABLE 6.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND LUNG CANCER

Study	Type and location	Subjects	Methods	Results	Comments
Fontham, et al., 1988 (Ref. 75).	Case-control, Los Angeles, California.	1,253 cases, 1,274 hospital controls matched for race, sex, age.	All subjects interviewed via questionnaire regarding tobacco use, diet, etc. Food frequency questionnaire used with reference period before appearance of symptoms.	An inverse association was found between intake of vitamin C and specific types of lung cancer. A similar but less strong association was found for carotene.	Control group had 31.6% nonsmokers versus 4.3% in the case group. No biochemical indices measured. No population-based control group. No comparisons were made to nutrient intake standards.
Koo, et al., 1988 (Ref. 76).	Case-control, Hong Kong.	88 cases, 137 district-matched controls. All subjects were women with no known history of smoking.	All subjects interviewed regarding demographics, etc. Diet information obtained from food frequency questionnaire.	Reduced risk of adenocarcinoma and large cell cancer associated with consumption of leafy green vegetables, carrots, tofu, fresh fruit, fresh fish. Reduced risk of squamous cell tumors associated with consumption of fresh fruits.	No biochemical measurements. No analysis of diet information for specific nutrients.
Le Marchand, et al., 1989 (Ref. 39).	Case-control, Hawaii.....	432 cases, males and females, 865 community controls matched for age and sex.	Structured interview provided data on smoking, alcohol use, diet, etc. Food frequency questionnaire given to all subjects.	Inverse association found between vitamin C from foods and supplements and risk of lung cancer. A dose-dependent negative association was found between dietary beta-carotene and risk of lung cancer.	No biochemical measurements. No controls for ethnic differences in intake.
Le Gardeur, et al., 1990 (Ref. 120).	Case-control, Los Angeles, California.	59 cases, 59 hospital controls, 31 community controls.	Cases and hospital controls interviewed regarding smoking, history, diet, etc. Community controls not interviewed. Blood samples collected from all.	Mean serum levels of carot-enoids, vitamin E were lower for lung cancer cases than for hospital controls. Hospital controls had lower levels of vitamins C and E than community controls.	No diet results reported. No diet data collected for community controls. Hospital control group not appropriate because of nature of illnesses.

TABLE 7.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCERS OF THE COLON AND RECTUM

Study	Type and location	Subjects	Methods	Results	Comments
Graham, et al., 1988 (Ref. 78).	Case-control, New York, N.Y.	428 cases of colon cancer, 428 controls matched for sex, age, neighborhood.	Interview consisted of food frequency questionnaire, smoking and alcohol use, health history, etc.	Increasing intake of tomatoes, peppers, carrots, onions, celery associated with decreased risk of colon cancer. Risk was positively associated with increasing intake of total fat and total calories.	No biochemical measurements. No reference period for food frequency questionnaire.
La Vecchia, et al., 1988 (Ref. 47).	Case-control, Italy.....	339 cases of colon cancer, 236 cases of rectal cancer, 778 hospital controls (acute nonneoplastic, nondigestive disorders).	Dietary information obtained from food frequency questionnaire.. Data also collected on demographics, smoking, alcohol use, etc.	Intake of green vegetables, tomatoes, melon, coffee inversely related to risk of colon and rectal cancers. Inverse relationship between indices of carotenoid and vitamin C intake and risk.	Variability in reference period among groups. No biochemical measurements. No population-based controls.
Neugut, et al., 1988 (Ref. 136).	Cross-sectional, New York, N.Y.	105 cases of polyps, 56 cases of colon cancer, 83 controls without neoplastic disease. All subjects were women who had undergone colonoscopy.	Questionnaire used to obtain information on demographics, health history. Subjects asked about use of vitamin supplements.	Significant differences in socio-economic factors among the groups.	No dietary information. No information on duration of supplement use. No biochemical measurements.

TABLE 7.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCERS OF THE COLON AND RECTUM—Continued

Study	Type and location	Subjects	Methods	Results	Comments
West, et al., 1969 (Ref. 80).	Case-control, Utah.....	231 cases of colon cancer, 391 controls matched by age, sex, county of residence.	Interviews provided information on demographics, health history. Food frequency questionnaire used to obtain dietary information.	Protective effects of beta-carotene and cruciferous vegetables in males and of fiber in females. No effects of vitamin C.....	No biochemical measurements. Relationship of reference period for dietary data and time of diagnosis not identified.
Freudenheim, et al., 1990 (Ref. 77).	Case-control, New York, N.Y.	422 cases of rectal cancer, 422 controls matched for sex, race, age.	Interview used to obtain information on food frequency, smoking, alcohol use, health history, etc.	Increasing intake of carotenoids, vitamin C, and dietary fiber from vegetables associated with decreased risk of rectal cancer.	No biochemical measurements. Reliance on retrospective food frequency information.
McKeown-Eyssen, et al., 1988 (Ref. 81).	Randomized double-blind intervention trial, Toronto, Canada.	185 cases with at least one colon or rectal polyp.	96 subjects received vitamins E plus C, and 89 received placebo over a 2 year period.. Food frequency questionnaire used to obtain dietary data.	137 participants completed the trial. There was no significant difference in the number of polyps found in vitamin-treated or placebo groups.	No biochemical measurements Small sample size Study design did not allow differences in effect of individual vitamins to be distinguished
De Cosse, et al., 1989 (Ref. 82).	Randomized double-blind intervention trial study. Participants from several states, United States.	58 patients with familial adenomatous polyposis who had total colectomy and ileorectal anastomosis 1 year prior to study.	Vitamin group received 2.2 g fiber and 4 g vitamin C and 400 mg vitamin E daily. Fiber group received both vitamins plus 22.5 g fiber daily. Control group received placebo and 2.2 g fiber daily. All groups received supplement of vitamins C and A, and several other vitamins and minerals daily.	There were no significant effects of the vitamins.	No biochemical measurements. Analysis of independent effects of vitamins was not possible because of design of the study.

TABLE 8.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND BREAST CANCER

Study	Type and location	Subjects	Methods	Results	Comments
Katsouyanni, et al., 1988 (Ref. 83).	Case-control, Athens, Greece.	120 cases, 120 hospital controls.	Dietary histories collected with a 120 item food frequency questionnaire. Nutrient intakes adjusted for calories.	No association between intake of vitamin C and risk of breast cancer. No differences in intakes of vitamin C between cases and controls.	No biochemical measurements. Supplement use not documented. 25% of controls had osteoarthritis, which affects vitamin C metabolism.
Toniolo, et al., 1989 (Ref. 84).	Case-control, Italy.....	250 cases, 499 controls from general population stratified by age, geographical area.	Dietary information collected by use of a modified food frequency questionnaire.	No differences in vitamin C intake between groups. Reduced risk of breast cancer was associated with decreased intakes of saturated fat and animal fat.	No biochemical measurements. Retrospective diet data not necessarily indicative of diets prior to diagnosis.
Howe, et al., 1990 (Ref. 85).	Case-control, meta-analysis of all studies of diet and breast cancer completed by 1986.	4,437 cases, 4,341 population-based controls, 1,754 hospital controls.	Data on vitamin C intake available from 9 to 12 studies. Estimates of intake were made for other three studies using food frequency answers.	Vitamin C intake had a statistically significant inverse association with risk of breast cancer. Consumption of B-carotene, fiber [markers of fruit and vegetable consumption] were also inversely related to risk.	Lack of control of independent variables that could be related to outcome. Reliability of dietary data questioned for some of studies used.

TABLE 9.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCER OF THE PROSTATE

Study	Type and location	Subjects	Methods	Results	Comments
Kolonel, et al., 1988 (Ref. 86).	Case-control, Hawaii	452 cases, 899 age-matched controls.	Home interview used to collect data on dietary, medical, occupational history, etc.. Food frequency questionnaire used to determine dietary intakes.	No associations were found between intake of vitamin C from food sources and risk of prostate cancer.	Total vitamin C intake ranged from 2,500 to 3,000 mg/week in all groups.
Ohno, et al., 1988, and Oishi, et al., 1988 (Ref. 43).	Case-control, Japan	100 cases of prostatic cancer, 100 controls with benign prostatic hyperplasia, 100 hospital controls without neoplasia or hyperplasia.. All subjects matched for hospital, age, date of admission.	Interviews used to collect data on occupation, medical history, etc. Dietary information obtained from food frequency questionnaire.	Intake of vitamin C from foods was not associated with risk of prostate cancer	No biochemical measurements. No community-based control group.

TABLE 10.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCER OF THE PANCREAS

Study	Type and location	Subjects	Methods	Results	Comments
Falk, et al., 1988 (Ref. 88).	Case-control, Los Angeles.	363 cases, 1,234 hospital controls matched on hospital. Race, sex, age	Interview used to obtain data on smoking, medical history, etc. Food frequency questionnaire used to obtain dietary information.	Significant inverse relationship between consumption of fruit (fresh or juice) and risk of pancreatic cancer.	No biochemical measures. Use of surrogates for more than 50% of cases. 13% of controls were not available.
Farrow, et al., 1990 (Ref. 137).	Case-control, Washington.	148 cases, 188 randomly selected controls.	Data for all subjects collected from surrogates. Food intake was determined from food frequency questionnaire.	No association between intakes of vitamin C and risk of pancreatic cancer.	Questionable validity/reliability of data acquisition.
La Vecchia, et al., 1990 (Ref. 48).	Case-control, Italy	247 cases, 1,089 hospital-based controls.	Interview used to obtain data on tobacco, alcohol, coffee intake, etc. Dietary intake of 14 "reference foods" determined.	Statistically significant decrease in risk of pancreatic cancer with increased intake of fresh fruits.	No biochemical measurements. No community based control. No matching for confounding variables.

TABLE 11.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND STOMACH CANCER

Study	Type and location	Subjects	Methods	Results	Comments
Burr, et al., 1987 (Ref. 94).	Cross-sectional, England, Wales.	267 and 246 subjects selected randomly from pools of men aged 65 to 74 years in two towns with differing death rates from stomach cancer.	Standardized questionnaire. Blood samples for ascorbate and pepsinogen.	Intake of fruit and plasma ascorbate levels were significantly higher in men from town with lower rates of stomach cancer.	No information on nature of food frequency questionnaire. No diet data provided. No matching of subjects by health history, smoking, demographics, etc.
You, et al., 1988 (Ref. 89).	Case-control, China	564 cases of stomach cancer, 1,131 population-based controls.	Dietary data obtained from a food frequency questionnaire. Reference periods were about 1980 and about 1965.	Increased consumption of vitamin C, carotene, and calcium (associated with high intakes of fruits, vegetables) associated with decreased risk of stomach cancer.	Data represented 1980 interviews. No biochemical measurements. No information on mean intakes of nutrients.
Buiatti, et al., 1989, 1990 (Refs. 91 and 92).	Case-control, Italy	1,016 cases of gastric cancer, 1,159 community controls matched for age, sex.	Interview used to obtain information about demographics, medical history, diet, etc.	Significantly reduced risk associated with increased intake of raw vegetables, fresh fruit, citrus fruit. Risk decreased in proportion to intake of vitamin C, beta-carotene, alpha-tocopherol and vegetable fat.	No biochemical data. Reliance on retrospective data. No comparison with known standards of intake.

TABLE 11.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND STOMACH CANCER—Continued

Study	Type and location	Subjects	Methods	Results	Comments
Chyou, et al., 1990 (Ref. 93).	Case-control, Hawaii.....	111 cases of gastric cancer, 361 controls. All subjects were American men of Japanese ancestry interviewed from 1965 to 1968.	Food frequency questionnaire provided information on food items consumed.	Statistically significant inverse relationship between risk of gastric cancer and intake of all vegetables.	No biochemical measurements. No assessments of individual nutrients.
Kono, et al., 1988 (Ref. 90).	Case-control, Japan.....	139 cases of stomach cancer, 2,574 hospital controls, 278 randomly selected community controls.	Data collected on dietary histories, occupation, smoking, etc.	Inverse relationship between risk of stomach cancer and consumption of fruits. Decreased risk also associated with increased consumption of green tea.	No biochemical measurements. No evaluation of individual nutrients. No information on health problems of hospital-based controls.

TABLE 12.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCERS OF THE HEAD AND NECK

Study	Type and location	Subjects	Methods	Results	Comments
Brown, et al., 1988 (Ref. 139).	Case-control, South Carolina.	207 males with esophageal cancer and 74 hospitalized cases and 133 deaths, 157 hospitalized noncancer controls and 265 noncancer deaths.	Patients interviewed about alcohol, tobacco use and diet. Next of kin of cancer and control subjects interviewed at home.	Leading risk factors for esophageal cancer after adjusting for smoking and tobacco use were low intakes of citrus fruits and juices and high intakes of liver.	No biochemical measurements. Reliance on retrospective dietary data and use of proxy data for mortality phase of study.
McLaughlin, et al., 1988 (Ref. 96).	Case-control, four regions of United States.	871 cases of oral and pharyngeal cancer, 979 population-based controls matched for age, sex, and race.	All subjects or next of kin provided data on alcohol and tobacco use and normal diet during adulthood.	Vitamin C was associated with decreased odds ratios and risk of oral cancer in men and women. There was a significant protective effect of vitamin C, vitamin A, and fiber derived from fruit.	No biochemical measurements. Reliance on retrospective diet data.
Franco, et al., 1989 (Ref. 95).	Case-control, Brazil.....	232 cases of oral cancer, 464 hospital, noncancer controls matched for sex, age, trimester of hospital admission.	All subjects interviewed regarding history of alcohol and tobacco use, general health, etc. Dietary information obtained from a food frequency questionnaire.	Strongest risk factors were alcohol and tobacco use. Without adjustments, significantly reduced risk associated with increased consumption of carrots, pumpkins, papaya, citrus fruits.	No biochemical measurements. No data on vitamin C specifically. Lack of population-based control group.
Li, et al., 1989 (Ref. 138).	Case-control, Linxian, China.	1,244 cases of cancer of esophagus or gastric cardia. 1,314 sex and age-matched controls from same area.	Data collected on smoking, diet history, personal health history. Questions were referenced to 2 time periods (late 1950's and late 1970's).	All subjects consumed diets low in fruits and vegetables. No association with risk of cancer at the sites examined.	Insufficient variability in intake to assess relationship to risk of cancer at sites examined.

TABLE 13.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCER OF THE OVARY OR CERVIX

Study	Type and location	Subjects	Methods	Results	Comments
Brock, et al., 1988 (Ref. 62).	Case-control, Australia.....	117 cases of cervical cancer, 196 controls matched for socio-economic status, age.	Interview and food frequency questionnaire used to obtain information on demographics, reproductive history, dietary data, etc.	Cases not matched for sexual habits, smoking, use of oral contraceptives. Adjusted risk estimate showed protective effect for vitamin C.	No biochemical measures of vitamin C status. No comparisons made with regard to dietary intake and blood levels.
Shu, et al., 1989 (Ref. 97).	Case-control, Shanghai....	172 cases of epithelial ovarian cancer, 172 controls (age-matched).	Interview used to obtain information on demographics, reproductive history, dietary intake, etc.	No effect of intake of vitamin C on risk of ovarian cancer.	No biochemical measurements. No descriptive statistics. No comparisons to known standards of intake.

TABLE 13.—ANTIOXIDANT VITAMINS AND CANCER: VITAMIN C AND CANCER OF THE OVARY OR CERVIX—Continued

Study	Type and location	Subjects	Methods	Results	Comments
Slattery, et al., 1989 (Ref. 44).	Case-control, Utah	85 cases of ovarian cancer, 492 population-based controls matched for age.	Interview provided data on demographics, health history, dietary intakes, etc.	No effect of intake of vitamin C on risk of primary ovarian cancer.	No reference period given for dietary data. No biochemical measurements.
Verrault, et al., 1989 (Ref. 63).	Case-control, Washington.	189 cases of cervical cancer, 227 randomly selected age-matched controls.	Demographic, dietary, etc. data collected by interview.	Decreased risk of cervical cancer associated with high intakes of vitamin C.	No biochemical measurements. Retrospective period was 2.7 to 2.8 years. Food portion sizes estimated from food composition tables.
Ziegler, et al., 1990 (Ref. 98).	Case-control, cross-sectional multi-multi-center study.	271 cases of cervical cancer, 502 controls matched by age, race, telephone exchange.	Data collected by interview. Medical history, family health, food intake data collected.	No effect of vitamin C or vitamin C-rich foods on risk of cervical cancer.	Cases confirmed during 1982 and 1983. No reference period relative to onset or symptoms of diagnosis in cases.

TABLE 14.—ANTIOXIDANT VITAMINS AND CANCER: OTHER STUDIES

Study	Type and location	Subjects	Methods	Results	Comments
La Vecchia, et al., 1989 (Ref. 49).	Case-control, Northern Italy.	163 cases of confirmed bladder cancer; 181 hospital controls.	All subjects interviewed for information about health history, alcohol, tobacco use, coffee consumption, etc. Dietary data obtained from food frequency questionnaire.	Bladder cancer cases had lower frequency of consumption of green vegetables, carrots. No reduced risk related to intake of vitamin C.	No biochemical measurements. Food frequency questionnaire had only 10 items.
Stahelin, et al., 1989 (Ref. 61).	Prospective cohort, Basel, Switzerland.	2,975 men, 102 cancer deaths (lung, 37; stomach, 17; colorectal, 9; others 39).	Samples were collected in 1971 to 1973 and analyzed immediately.	Vitamin C was significantly lower in cases of stomach cancer than in controls.	Reliance on point sample analysis. No dietary data.

TABLE 15.—ANTIOXIDANT VITAMINS AND CANCER: PROSPECTIVE STUDIES ON VITAMIN E AND CANCER

Authors/year	Source/exposure	Study population	Cancer site	Cases/controls	Results	Assessment of the study
Wald, et al., 1987 (Ref. 57).	Serum vitamin E	22,000 men, 35 to 64 years, London, England.	Lung, colorectal, stomach, bladder, CNS, skin, other sites, all sites.	9/17, 6/12, 3/6, 8/15, 5/10, 31/57, 28/55, 90/172.	Mean vitamin E level of the cases was not significantly different from the controls in cancer subjects diagnosed >1 year after blood collection. Vitamin E levels of cancer cases diagnosed <1 year after blood collection was significantly lower than controls.	No dietary use data or data on the health history of the controls. Cases per cancer site were small. The difference reported for cases diagnosed at <1 year may have been the consequence of cancer rather than the precursor.
Russell, et al., 1988 (Ref. 117).	Serum vitamin E	5,086 women, 26 to 88 years, Guernsey, England.	Breast	30/288	No significant difference between the serum vitamin E levels of cases with breast cancer and the controls.	No matching for smoking, long storage time of the samples and no dietary use data.
Gey, et al., 1987 (Ref. 109).	Plasma vitamin E	3,000 men, Basel, Switzerland.	All sites, lung, gastrointestinal survivors.	102, 37, 17, 2,707	Significantly lower plasma vitamin E levels were associated with overall cancer and combined gastrointestinal cancer mortality.	No dietary use data. Small size was very small per site.
Stahelin, et al., 1989, 1991 (Refs. 60 and 61).	Plasma vitamin E	2,974 men Basel, Switzerland.	Bronchial, stomach, gastrointestinal, colon, survivors.	68, 20, 37, 17, 2,421.	No significant association of plasma vitamin E and the risk of cancer.	No dietary data. Results did not confirm findings reported in an earlier study using the same population group.

TABLE 15.—ANTIOXIDANT VITAMINS AND CANCER: PROSPECTIVE STUDIES ON VITAMIN E AND CANCER—Continued

Authors/year	Source/exposure	Study population	Cancer site	Cases/controls	Results	Assessment of the study
Schober, et al., 1987 (Ref. 116).	Serum vitamin E	25,802 adults, Washington County, Maryland.	Colon	72/143	No significant association of serum vitamin E and colon cancer.	No dietary data and long storage time of the sera samples.
Burney, et al., 1989 (Ref. 115).	Serum vitamin E	25,620 adults, Washington County, Maryland.	Pancreas	22/44	Low levels of serum vitamin E appear to have a protective effect on pancreatic cancer.	A chance association between vitamin E and pancreatic cancer could not be excluded. Samples were stored for a long time period and there was no information on diet history or intake. The number of cases was also very small.
Comstock, et al., 1991 (Ref. 114).	Serum vitamin E	25,800 adults, Washington County, Maryland.	Colon; rectum; pancreas; lung; melanoma, skin; basal cell, skin; Breast; Prostate; Bladder.	72/143, 34/68, 22/44, 99/196, 20/40, 21/42, 30/59, 103/103, 35/70.	The association of vitamin E with lung cancer showed a dose-response trend in a protective direction. There were no other significant associations.	Storage time of samples was very long, sample size at some cancer sites was small and no diet history or usage reported.
Knekt, et al., 1988 (Ref. 112).	Serum vitamin E	36,265 men and women, 15 to 99 years, Finland.	Gastrointestinal	150/276	Upper gastrointestinal tract cancers were associated with lower serum vitamin E. The risk differed significantly between tertiles among men.	Samples collected and stored a long time before analysis of vitamin E and no diet usage data were reported.
Knekt, et al., 1988 (Ref. 111).	Serum vitamin E	21,172 men, Finland	All sites, Stomach, Pancreas, Colon and rectum, Other sites.	453/841, 48/90, 17/28, 21/39, 367/723.	Significant increase in the risk for all cancers unrelated to smoking and some gastrointestinal cancers with low serum vitamin E.	The number of cases at certain sites was small, samples were stored for a long period of time and no dietary data were reported.
Knekt, et al., 1988 (Ref. 110).	Serum vitamin E	15,093 women, Finland.	All sites, Epithelial, Breast, Cervix, Endometrium, Ovary.	313/578, 184/339, 67/123, 23/44, 12/21, 16/29.	Significant inverse association between serum vitamin E for all cancer sites combined and epithelial cancer.	The number of cases at some sites was small, samples were collected and stored a long time before analysis of vitamin E and no dietary data reported.
Knekt, et al., 1991 (Ref. 113).	Serum vitamin E	36,265 men and women, Finland.	All sites, Gastrointestinal.	557 sets, 160 sets.	The association of serum vitamin E with cancer was strongest for all cancer sites and gastrointestinal cancer.	Same as above.

TABLE 16.—ANTIOXIDANT VITAMINS AND CANCER: RETROSPECTIVE STUDIES ON VITAMIN E AND CANCER

Authors/year	Source/exposure	Location	Cancer site	Cases/controls, type of control	Results	Assessment of the study
Basu, et al., 1989 (Ref. 118).	Serum vitamin E	Canada	Breast	30/30, Population	No significant association between breast cancer and serum vitamin E.	All cases were in the advanced stage of breast cancer. No dietary or clinical data were reported. Sample size was small.
Gerber, et al., 1989 (Ref. 119).	Vitamin E intake Plasma Vitamin E	France	Breast	120/109, Hospital	Plasma vitamin E was significantly higher in cases than controls.. No significant association of vitamin E intake and breast cancer.	The control group was made of hospital patients and no information was given on medication use. Dietary data were retrospective.

TABLE 16.—ANTIOXIDANT VITAMINS AND CANCER: RETROSPECTIVE STUDIES ON VITAMIN E AND CANCER—Continued

Authors/year	Source/exposure	Location	Cancer site	Cases/controls, type of control	Results	Assessment of the study
Toniolo, et al., 1989 (Ref. 84).	Vitamin E intake		Breast	250/499, Population.	No significant association of vitamin E intake and breast cancer.	No biochemical data were reported. Dietary data were retrospective and obtained on the average of 7.8 months after diagnosis.
LeGardeur, et al., 1990 (Ref. 120).	Serum vitamin E	New Orleans, Louisiana.	Lung	59/59, Hospital	Lower serum vitamin E of cases when compared with controls.. Adjustment for serum cholesterol reduced the differences.	No dietary data were reported. Hospital patients who may have been predisposed to changes in serum vitamin E were used as controls. Groups were not matched for smoking history.
Charpiot, et al., 1989 (Ref. 121).	Serum vitamin E	France	Digestive	50/50, Hospital	Serum vitamin E of cases were significantly lower than controls.	Dietary intake information was not reported. No information was provided on whether the hospitalized controls were on any medication. Data were not provided on the stage or type of digestive cancer.
Buiatti, et al., 1990 (Ref. 92).	Vitamin E intake	Italy	Gastric	1,016/1,159, Population.	Risk decreased with increased intakes of vitamin E and C.	No biochemical data were reported. Retrospective dietary data on vitamin E were calculated using English tables.
Verrault, et al., 1989 (Ref. 63).	Vitamin E intake	Seattle, Washington	Cervical carcinoma	189/227, Population.	High vitamin E intake was associated with lower cancer risk.	No biochemical data were reported. Retrospective dietary data focused on the recall of foods use several years prior to the interview.
Cuzick, et al., 1990 (Ref. 122).	Serum vitamin E	London	Cervical intraepithelial neoplasia I, Cervical intraepithelial neoplasia II.	30/40, 40/45. Patients of general practitioners and clinics.	Significant decreasing trend of mean levels of serum vitamin E in cases.	No dietary data reported. Sample size was small. No medical history of controls was reported.
Freudenheim, et al., 1990 (Ref. 77).	Vitamin E intake	Western New York	Rectal	277/277 (men), 145/145 (women), Neighborhood.	No significant association between rectal cancer and vitamin E intake.	No biochemical data reported and retrospective food frequency interviews were used.
Stryker, et al., 1990 (Ref. 125).	Plasma vitamin E, Vitamin E intake.	Boston	Malignant melanoma.	204/248, Skin clinic.	Intake alone displayed a significant trend of decreasing risk with increasing intake.	Clinic patients were used as controls and no information was reported on medication or supplement use.
Drozdz, et al., 1989 (Ref. 124).	Serum vitamin E	Poland	Larynx	22/16, Hospital	No significant association of serum vitamin E and cancer of the larynx.	Hospital controls were used who may have been predisposed to changes in serum vitamin E. No diet or supplement information were reported. Sample size was very small.

[Docket No. 91N-0102]

RIN 0905-AD08

Food Labeling: Health Claims; Zinc and Immune Function in the Elderly

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing not to authorize the use on foods, including dietary supplements, of health claims relating to the association between zinc and immune function in the elderly. FDA has reviewed the scientific data in conformity with the requirements of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) and has tentatively concluded that there is not a sufficient basis to support the use of health claims relating to this topic. The agency's examination of publicly available evidence revealed that a specific protective role of zinc supplementation of the elderly population has not been demonstrated. Although some small clinical studies suggested such a relationship, these results were not substantiated in subsequent research using better study designs and larger samples.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

FOR FURTHER INFORMATION CONTACT: James E. Hoadley, Center for Food Safety and Applied Nutrition (HFF-268), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-472-5104.

SUPPLEMENTARY INFORMATION:

I. Background

A. Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101-535), which amend the Federal Food, Drug, and Cosmetic Act (the act). Section 403(r) of the act (21 U.S.C. 343(r)) authorizes the Secretary of Health and Human Services and FDA by delegation to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this Federal Register is a proposed rule to establish general requirements for health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs, or other nutritional substances (referred to generally as "substances") to a disease or health-related condition on food labels and in labeling for conventional foods and dietary supplements. In this companion document, FDA has tentatively determined that such claims would only be justified for substances in dietary supplements as well as in conventional foods if it determines, based on its review of all the publicly available scientific evidence (including evidence from well designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (sections 3(b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)) that within 12 months of enactment, the Secretary of Health and Human Services shall issue proposed regulations to implement section 403(r) of the act and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including zinc and immune function in the elderly, meet the requirements of the act.

In this document, the agency will consider whether a label or labeling claim on a food, including conventional foods and dietary supplements, on the relationship between zinc and immune function in the elderly would be justified under the standard proposed in the companion document entitled "Food Labeling: General Requirements for Health Claims for Food.

B. Zinc and Immune Function in the Elderly: Public Health Aspects

1. Zinc and Immune Function

Immune function refers to the body's defense processes to prevent and contain infection. The immune system is composed of lymphoid, thymus, and bone marrow cells. Poor nutrition (for example, malnutrition consisting of inadequate protein and calorie intake and multiple nutrient deficiencies) increases susceptibility to infectious disease (Refs. 1 through 4). In addition, diminished immune function is recognized as an adverse consequence of deficiencies of several specific nutrients including iron, zinc, copper, magnesium, selenium, vitamin E, vitamin C, vitamin B_6, vitamin B_{12}, and folic acid. The effect that a deficiency in a particular nutrient has on immune function in human populations is not well understood. Zinc deficiency and immune function have been investigated extensively because studies in humans and animals have shown that zinc deficiency causes a selective suppression of lymphoid organ weight and abnormalities in immune responses.

Experiments in zinc-deficient animals and humans have shown that zinc is essential for specific immune function (Refs. 5 through 8). Immunological disorders of some disease conditions characterized by secondary zinc deficiencies can be corrected by zinc supplementation (Refs. 5 and 7). Such disease states and conditions include acrodermatitis enteropathica, alcoholism, diabetes, gastrointestinal disorders, sickle cell anemia, some cancers, protein-calorie malnutrition, parenteral nutrition with inadequate zinc, and hypoglobulinemia. There is no evidence, however, that immune function in healthy persons can be enhanced by zinc supplementation.

Zinc is considered to be relatively nontoxic, particularly if taken orally. However, adverse effects, which include impaired immune function, are known to occur with zinc intake in excess of the Recommended Dietary Allowance (RDA) (Ref. 9).

2. Mechanisms and Measures of Immune Function

The immunologic defense mechanisms mediated by T lymphocytes are collectively known as "cell-mediated immunity." T. lymphocytes, a specific type of white blood cell, attack and kill cells infected with viruses, bacteria, and protozoa. Thymic hormone stimulates maturation and differentiation of immature lymphocytes into several specific types of functional T lymphocytes. Thymic hormone requires zinc for activation. Various subsets of differentiated T lymphocytes (e.g., "helper", "suppressor", and "killer" T cells) can attach to infected cells and kill them directly or can function indirectly by releasing substances that influence the actions of other immune cells.

Several common tests are used to measure the level of cell-mediated

immune function. In the delayed cutaneous hypersensitivity (DCH) test, a small amount of foreign substance (an antigen) is injected under the skin. With normal functioning cell-mediated immunity, a localized inflammatory reaction develops at the site of the injection within 48 hours. The immune response to the antigen is measured by the diameter of the welt and inflammation appearing at the site. "Anergy" is a term used to describe the condition in which no cell-mediated allergic reaction occurs in response to such antigen injection.

Another type of test of cell-mediated immunity uses lymphocytes separated from blood samples and cultured in test tubes. Addition of a small amount of mitogen (a substance such as bacterial fragments) to the isolated lymphocytes stimulates functional, immunocompetent T lymphocytes to divide and proliferate. Impaired cell-mediated immunity is indicated by a failure of the mitogen to stimulate T lymphocyte proliferation. The lymphocyte proliferative response (LPR) is a measure of the rate of lymphocyte division in response to a mitogen challenge.

Zinc deficiency has been associated with decreased thymic hormone levels and with a corresponding decrease of both functional T lymphocytes and cell-mediated immunity in experimental animals and humans, as shown by anergy in DCH and decreased LPR (Refs. 8 and 10).

3. Immune Function in Aging

One of the physiologic changes that characterizes aging is a gradual senescence of some components of the immune system, particularly cell-mediated immune function (Refs. 5, 11, and 12). The primary age related changes in immune systems of both human and experimental animals result from gradual thymic atrophy and changes in the T lymphocyte population. There are age related decreases in the number of blood T lymphocytes as well as in the proportion of helper/inducer T lymphocytes and increases in the proportion of immature T lymphocytes. Accompanying the change in T cell population is a functional decline in cell-mediated immunity as indicated by reduced lymphocyte proliferation in response to mitogens.

Progressive impairment of cellular immunity observed in generalized malnutrition, including zinc deficient states, is similar in some respects to the age related decline of cell-mediated immune function. When insufficient protein calorie nutrition is responsible for depressed immune function, improved diet may restore such function and improve disease resistance. There is evidence that a balanced, complete nutritional supplementation can improve impaired cell-mediated immunity in protein-calorie malnourished elderly (Ref. 13).

4. Zinc Nutritional Status of the Elderly in the United States

Several reports have suggested that the elderly U.S. population may be at risk of zinc deficiency. A review of reports by 17 different groups concerning zinc intake in the elderly has recently been published (Ref. 14). The results of dietary surveys have been fairly consistent in suggesting that elderly persons consume zinc at less than RDA levels. Diets representative of those consumed by elderly women generally contain less dietary zinc than do those for elderly men (Ref. 15), and institutionalized subjects generally consume less zinc than do persons living at home (Refs. 16 and 17).

Intake of zinc appears to diminish as elderly persons advance in age (Refs. 14 and 18). Small studies of selected populations have also identified pockets of zinc insufficiency in some populations (Ref. 14). Additionally, the elderly frequently alter their dietary habits and may also lose their appetites and reduce their food intake (i.e., become anoretic).

For these reasons, the elderly population has been proposed as one of the groups which may have a high incidence of inadequate zinc nutriture (Refs. 19 through 21). The question of adequacy of zinc nutriture in the elderly is one of the issues that FDA examined in this review.

C. Zinc: Regulatory History

One zinc salt, zinc methionine sulfate, is regulated as a direct food additive for use as a special dietary and nutrient food additive in 21 CFR 172.399.

Five other zinc salts are listed in part 182 (21 CFR part 182) as generally recognized as safe (GRAS) for use in dietary supplements or as nutrients: Zinc chloride (§§ 182.5985 and 182.8985), zinc gluconate (§§ 182.5988 and 182.8988), zinc oxide (§§ 182.5991 and 182.8991), zinc stearate (§§ 182.5994 and 182.8994), and zinc sulfate (§§ 182.5997 and 182.8997). No zinc compounds are affirmed as GRAS in part 184—Direct Food Substances Affirmed as Generally Recognized as Safe (21 CFR part 184) nor under part 186—Indirect Food Substances Affirmed as Generally Recognized as Safe (21 CFR part 186). FDA proposed to affirm the GRAS status of the use of zinc salts in a document published on October 26, 1982 (47 FR 47441). FDA proposed to affirm as GRAS the use of zinc oxide and zinc sulfate as direct food ingredients, to affirm as GRAS the use of zinc chloride as an indirect food ingredient, and to remove zinc chloride and zinc stearate from the listing in part 182 (§§ 182.8985 and 182.8994). For technical reasons not related to the safety of the compounds,

FDA proposed on August 28, 1991 (56 FR 42668) to withdraw pre-1986 GRAS proposals, one of which is the use of zinc salts.

FDA has issued a health fraud bulletin pertaining to drug products, including vitamins and minerals, that bear claims that they enhance, strengthen, or otherwise benefit the immune system for the purpose of preventing or treating any disease condition. The bulletin stated that such products are drugs under section 201(g)(1)(B) of the act (21 U.S.C. 321(g)(1)(B) (FDA Health Fraud Bulletin No. 11. *Immune System Products*, August 17, 1987).

D. Evidence Considered in Reaching the Decision

FDA has reviewed all relevant scientific evidence on zinc and immune function in the elderly. The scientific evidence reviewed by FDA included all relevant studies considered in two U.S. Government documents: "The Surgeon General's Report on Nutrition and Health," U.S. Department of Health and Human Services, 1988 (Ref. 22) (the Surgeon General's report) and the U.S. Department of Agriculture (USDA) and DHHS pamphlet "Nutrition and Your Health, Dietary Guidelines for Americans" (Ref. 23). FDA reviewed relevant studies considered in three nongovernment documents: the National Research Council's report "Diet and Health: Implications for Reducing Chronic Disease Risk," National Academy of Sciences (Ref. 24), the Tenth Edition of "Recommended Dietary Allowances" (Ref. 25) and the Life Sciences Research Office of the Federation of American Societies of Experimental Biology report "Zinc and Immune Function in the Elderly" (Ref. 26) (the Life Science Research Office report). FDA updated the conclusions reached in these documents by reviewing all human studies and all review articles relevant to the topics that were published in the literature since the publication of these documents.

To assure that its review of relevant evidence was complete, FDA requested, in the **Federal Register** of March 28, 1991, (56 FR 12932) scientific data and information on the 10 specific topic areas identified in section 3(b)(1)(A) of the 1990 amendments. The topic of zinc and immune function in the elderly was

among the 10 subjects on which the agency requested information.

E. Comments Received in Response to FDA Request for Scientific Data and Information

In response to the March 28, 1991 notice in the **Federal Register**, FDA received six comments from food manufacturers or processors, trade associations of dietary supplement manufacturers, national associations of public health and nutrition officials, and the Government of Canada. The comments dealt with the issue of zinc and immune function in the elderly as well as with the goals and requirements of the 1990 amendments. One comment was from a private citizen, who submitted a computer search of medical literature. FDA reviewed all of the documents, including letters, press releases, scientific articles, review articles, and recommendations included in submissions that it received. The data submitted in scientific articles were included in FDA's review of the scientific literature.

Comments from a food manufacturer and from a trade association of nutrient supplement manufacturers included a recommendation that FDA include additional population groups and additional nutrients in its evaluation of nutrition/immune function relationships for label health claims. Another comment noted that dietary intake data from several sources indicate that the zinc intake of several age groups is less than the RDA. One comment noted that although there is not sufficient data at this time to support disease related claims for the population, including the elderly, it is important to encourage adequate consumption of zinc.

Comments were received from two national professional organizations of nutritionists and public health nutrition directors. These comments advised a cautious approach to the use of health claims on foods and supplements with awareness of the potential for abuse and misinterpretation of health claims. The comments recommended that the cornerstone for approval of a health claim be significant scientific agreement that the claim is supported by publicly available evidence, and that health claims be evaluated in the context of the total diet rather than on the basis of individual foods, supplementation, or fortification practices.

The Government of Canada submitted information that it considers helpful in the context of increased harmonization of regulations or standards affecting trade in specific products. The Canadian Food and Drugs Act prohibits advertising and labeling of a food as a treatment, preventative, or cure for specific diseases and disorders listed in the act. The Director General, Food Directorate, Health and Welfare Canada, stated that although immune function is not included in the act, health claims regarding zinc and immune function in the elderly would likely result in a food product being classified as a drug by virtue of the definition of "drug" embodied in the Canadian Food and Drugs Act.

The official position of Canada on the relationship of diet and nutrients to disease and the metabolic effects of nutrients is stated in "Nutrition Recommendations, the Report of the Scientific Review Committee—1990" (Ref. 27) (the Canadian Report). In sections relating to zinc and disease prevention, this report noted that abnormal zinc intakes have been associated with impaired immune function. Zinc supplementation of zinc-deficient persons improves many aspects of immune function. The report did not specifically address the issue of zinc and immune function in the elderly.

The Canadian report noted that excessive intakes of zinc have been shown to impair immune function and to cause adverse effects on copper metabolism (Ref. 27). In view of potential detrimental effects of high intakes of zinc on the immune system and on copper metabolism, the Canadian report suggested that large supplementary amounts of the element be avoided. There is no scientific evidence, the Canadian report continued, to support ingestion of megadoses of zinc except in the treatment of specific diseases such as Wilson's disease, in which excess copper is absorbed and stored in the body. The recommended zinc intakes for Canadian adult males and females (over 13 years of age) are 12 and 9 milligrams (mg) zinc per day, respectively (Ref. 27).

II. Review of the Scientific Evidence

A. Federal Government Documents

The Joint Nutrition Monitoring Evaluation Committee (JNMEC) DHHS/USDA, was established in 1983 by the USDA and DHHS to coordinate survey methods used by the two departments to obtain information on nutritional status of the U.S. population. The first report (Ref. 28), issued in 1986, provided food intakes data from the 1977 to 1978 Nationwide Food Consumption Survey (NFCS) and information on nutritional status based upon biochemical analyses from the National Health and Nutrition Examination Survey (NHANES II, 1976 to 1980). JNMEC judged that zinc was among a number of nutrients and dietary components that required further investigation because data regarding intake and nutritional status were inadequate (Ref. 28).

The "Surgeon General's Report on Nutrition and Health" (Ref. 22) did not consider the specific topic of zinc and immune function in the elderly. In sections dealing with infection and immunity and with aging, however, the Surgeon General's Report (Ref. 22) noted that deficiencies of a number of nutrients have been associated with reduced function of specific components of the immune system, and that during aging there is a gradual senescence of some components of the immune system. The Surgeon General's report pointed out, however, that distinguishing age related physiologic changes from those changes caused by poor nutrition in older persons has not yet been possible (Ref. 22). The Surgeon General's report observed that research has not yet resolved whether progressive impairment of cellular immunity with age might cause older populations to have more infections than young people of equivalent nutritional and health status. The relationships among malnutrition, infections, and changes in immune system function in elderly persons have yet to be clarified (Ref. 22).

The Surgeon General's Report (Ref. 22) further noted that nutritional status evaluation of older people is complicated, and that clinical and dietary standards for younger adults may not be appropriate for older persons. Few data are available on nutritional requirements of older adults. A very serious problem in nutritional status assessment of older adults is the lack of correlation between dietary intake data and clinical and laboratory assessment methods (Ref. 22).

B. Other Documents

The Food and Nutrition Board of the National Academy of Sciences did not specifically address the topic of zinc and immune function in the elderly in the Tenth Edition of "Recommended Dietary Allowances," (Ref. 25). The Food and Nutrition Board concluded that marginal states of zinc nutriture may exist in segments of the U.S. population, but that the data are fragmentary.

The Life Sciences Research Office report reviewed the literature on the relationship between zinc and immune function in the elderly (Ref. 26). This report concluded that:

(1) Zinc is of profound importance for proper immune system function. Too much or too little zinc can induce immunological dysfunctions. Steps to

return zinc nutriture to normal serve to correct such dysfunction;

(2) Elderly persons who are poor, who live alone or in institutions, who are female, who have acute or chronic illnesses or disabilities, or who reach very advanced ages are at risk for developing zinc malnutrition;

(3) Immunological dysfunctions in the elderly have been improved by nutritional means, but the role of zinc in this remains unclear. Reported immune system improvements induced by supplemental zinc generally occurred in subjects with preexisting evidence of zinc deficiency;

(4) RDA intakes of zinc may not correct preexisting zinc deficiencies in the elderly. Even large supplements may not improve plasma zinc values if disease induced zinc sequestering mechanisms are involved; and

(5) There is no definitive evidence to suggest that the current RDA for zinc is inadequate for healthy elderly individuals. Elderly persons who are truly zinc deficient may benefit immunologically from medically supervised nutritional rehabilitation.

C. Review of Scientific Literature

1. Evidence for an Association Between Zinc Intake and Immune Function in the Elderly

a. *Introduction.* FDA reviewed all the publicly available evidence on zinc and immune function in the elderly provided by intervention studies. The agency evaluated these human intervention studies to determine whether there is an association between zinc supplementation and improvements in immune function in this age group. Pertinent information regarding these studies, such as study design, number of subjects studied, nature and duration of supplement use, and significant results are included in Table 1. The evaluation focused on studies in which supplemental zinc was administered to healthy elderly persons to determine whether zinc had specific effects on the immune system function of the general population for which health claims are targeted.

TABLE 1.—ZINC AND IMMUNE FUNCTION IN THE ELDERLY: SUPPLEMENTATION STUDIES

Reference	Study design and duration	Description of subjects	Test material and intake level	Diet	Additional treatments	Other factors affecting interpretation	Results	Assessment of study
Duchateau et al., 1981 (Ref. 29).	Prospective intervention study with controls; 1 month.	30 healthy institutional patients, age >70 years; test group (n=15), control group (n=15); Belgium.	Zinc (Zn) sulfate; 100 mg Zn/day orally.	Not reported.....	Tetanus vaccination.	Institutionalized subjects only. No measure of Zn status. No blinding.	20% increase of T lymphocytes ($p<.05$), improved DCH response ($p<.01$), and greater post vaccine tetanus titre ($p<.001$) in treated group. No change of in vitro LPR.	Results not applicable to free-living elderly. Immunological improvement small, no assessment of initial Zn status.
Wagner et al., 1983 (Ref. 30).	Prospective intervention study, not controlled; 1 month.	5 anergic, low income elderly, age 64 to 76 years; Alachua Co., FL.	Zinc sulfate; 55 mg Zn/day orally.	Self-selected.....	None.....	Incomplete serum data from 1 subject. Low income subjects only. All subjects initially anergic.	All 5 subjects had at least 1 positive DCH response from 5 test antigens. Serum Zn increase.	Small, uncontrolled, unblinded study.
Bogden et al., 1988 (Ref. 34).	Prospective double-blind intervention study; 3 months.	103 healthy free living elderly, age 60 to 89 years, 3 groups: placebo (n=36), 15 mg Zn (n=36), 100 mg Zn (n=31); Bergen Co., NJ.	Zinc acetate, 15 mg Zn/day, 100 mg Zn/day, 0 mg Zn/day (lactose placebo) orally.	Self-selected 8 to 9 mg Zn/day.	Multiple vitamin-mineral (-Zn) oral supplement.	Free living healthy subjects. Compliance monitored by pill counts.	Plasma Zn increase ($p<.05$) in 100 mg Zn group. Increase DCH response in all groups. Decrease anergy same in all groups. No change of in vitro LPR.	Large, well conducted study, no differences were found in immune functions between placebo and Zn supplemented groups. No effect of supplemental Zn on immune function.
Bracker et al., 1988 (Ref. 35).	Prospective double-blind intervention study; 2 months.	41 healthy elderly, age 64 to 90 years, Zn supplemented group (n=23), placebo group (n=18); California.	Zinc gluconate; 0 mg Zn/day (placebo) 50 mg Zn/day orally.	Not reported.....	Trivalent influenza vaccine at 1 month.	41 of 60 subjects (68%) completed study. Dietary assessment not included.	45% increase in serum Zn in supplemented group ($p<.001$). Post vaccination antibody titre increase not different between supplement and placebo groups.	Limited to healthy subjects, results can be generalized to U.S. population. Previous influenza vaccination may have influenced results.
Soltesz et al., 1988 (Ref. 31).	Prospective intervention study; 4 weeks.	6 nursing home residents, age not specified. Ohio.	Zinc gluconate; 15 mg Zn/day orally.	Institutional food; 6.8 to 13 mg Zn/day calculated intake.	One subject received liquid nutritional supplements.	Nursing home patients, screened for confounding problems. Age not specified. Data from 5 subjects.	Small increase in number of positive DCH responses $p<05$, n=5).	Small, uncontrolled, unblinded study; immunological improvement small.
Cossack, 1989 (Ref. 32).	Prospective intervention study; 4.5 months.	8 Zn deficient, low income elderly men, age 65 to 78 years Denmark.	Zinc acetate; 60 mg Zn/day orally.	Not reported.....	None.....	Comparison values from 13 age matched men. Subjects selected from group of low socioeconomic men on basis of low Zn status and anergy.	Plasma and cellular Zn levels increase to normal DCH response and RBC[1] nucleoside phosphorylase activity increase to near normal.	Small, uncontrolled, unblinded study. Results applicable only to individuals diagnosed as Zn deficient.

Bogden et al., 1990 (Ref. 34).	Prospective double-blind intervention study; 16 months overall, last 4 months all groups received placebo.	63 healthy free living elderly, age 60 to 389 years; 3 groups: placebo (n=24), 15 mg Zn (n=20), 100 mg Zn (n=19); Bergen Co., NJ.	Zinc acetate 15 mg Zn/day, 100 mg Zn/day, 0 mg Zn/day, (placebo) orally.	Self-selected; Zn intake less than 2/3 RDA for 67% of men and 81% of women.	Multiple vitamin-mineral (-Zn) oral supplement continued for 16 months.	Free living healthy subjects. 63 of 158 subjects (40%) completed 16 months. Zn supplementation for 12 months, all groups received placebo final 4 months. Compliance monitored by pill counts.	Plasma Zn increase ($p<.05$) in 100 mg Zn group, returned to baseline at 16 months. No change in cellular Zn except for transient increase of PMN[2] Zn at 3 months in 15 mg Zn group. DCH response increased in all groups, doubled in placebo group, increased least in Zn supplement groups DCH suppression in Zn groups persisted after Zn supplementation discontinued. Transient increase NK cell activity at 3 month in 100 mg Zn group.	Large, well conducted study. Improvements in immune function likely due to multivitaminminer supplement, and suppressed by supplemental Zn.
Soltesz et al., 1988 (Ref. 31).	Prospective intervention study; 4 weeks.	6 nursing home residents, age not specified. Ohio.	Zinc gluconate; 15 mg Zn/day orally.	Institutional food; 6.8 to 13 mg Zn/day calculated intake.	One subject received liquid nutritional supplements.	Nursing home patients, screened for confounding problems. Age not specified. Data from 5 subjects.	Small increase in number of positive DCH responses ($p<.05$, n=5).	Small, uncontrolled, unblinded study; immunological improvement small.
Cossack, 1989 (Ref. 32).	Prospective intervention study; 4.5 months.	8 Zn deficient, low income elderly men, age 65 to 78 years Denmark.	Zinc acetate; 60 mg Zn/day orally.	Not reported.....	None	Comparison values from 13 age matched men. Subjects selected from group of low socioeconomic men on basis of low Zn status and anergy.	Plasma and cellular Zn levels increase to normal DCH response and RBC nucleoside phosphorylase activity increased to near normal.	Small, uncontrolled, un blinded study. Results applicable only to individuals diagnosed as Zn deficient.

[2] Polymorphonuclear cells.

FDA did not review studies of: (1) Influence of zinc on immune function in disease states; (2) effects of in vitro addition of zinc to lymphocytes; or (3) animal studies. The results of studies of immune function in malnourished populations and in specific disease states are widely reported in the scientific literature (Refs. 1 through 8, and 10). Such studies, however, do not contribute specific information helpful in evaluating the relationship of zinc to immune function in the elderly because it is difficult to identify the role of zinc versus other nutrient insufficiencies or to extrapolate from sick persons to the general population of healthy elderly in the United States. To the extent that zinc is used to cure, treat, or mitigate a disease, it is a drug (21 U.S.C. 321(g)(1)(B)).

The relevance of findings of effects of addition of zinc to lymphocytes in vitro to function of the immune system in vivo is simply not clear. Studies with animals have repeatedly demonstrated the effects of zinc deficiency on immune function. Thus, the existence of a role for zinc in immune function is not at issue. However, animal studies in general, while providing invaluable insights into the role of nutrition in immune function, do not contribute directly to an understanding of zinc and immune function in the elderly human population in the United States, the subject that the statute directs FDA to consider.

b. *Criteria used in evaluating evidence.* The criteria used in evaluating evidence included: (1) Reliability and accuracy of the methods used in food intake analysis and measurement of endpoints; (2) choice of control subjects (e.g., hospital-based versus population-based); (3) representativeness of subjects; (4) control of confounding factors in data analysis; and (5) degree of compliance and how compliance was assessed.

FDA evaluated the weaknesses and strengths of individual studies (see "Assessment" column of Table 1). The agency then assessed the strength of the overall combined evidence taking into account the strength of the association, the consistency of findings, and specificity of the association. FDA's conclusions reflect the strength, consistency, and preponderance of data.

c. *Review of evidence.* In 1981 Duchateau et al. (Ref. 29), published the first report of an effect of zinc supplementation on immunocompetence in healthy elderly persons. Two age and sex matched groups of institutionalized healthy persons over 70 years old were studied. One group (n=15, mean age=81) received 100 mg zinc per day orally for 1 month; the second group (n=15, mean age=80) received no supplement and served as a nonblinded control group. No measures of zinc status nor of dietary zinc intake were reported in the study. Several measures of cell-mediated immunity (proportion of T cell lymphocytes, DCH response, and antibody response to tetanus toxoid vaccination) increased in the zinc supplemented group but not in the control group. No differences between groups were noted for other indicators of immunocompetence, i.e., in vitro LPR to mitogens and numbers of circulating leukocytes or total lymphocytes. Side effects, including transient nausea and mild diarrhea, were noted in 5 of 15 zinc supplemented subjects (Ref. 29).

Another report associating zinc supplementation and improved immunocompetence in the elderly, as measured by DCH response, was reported in 1983 by Wagner et al. (Ref. 30). Five low income elderly (age 64 to 76 years) individuals in Alachua County, FL, who showed no DCH responses on two occasions before zinc supplementation, were supplemented with 55 mg zinc per day orally. Following one month of supplementation, all five subjects developed a positive DCH response to at least one of five test antigens. Serum zinc concentration increased in the four subjects for whom both initial and final serum samples were obtained. A control group was not included in this study, and only a single indicator of immunocompetence was measured (Ref. 30).

A study of six elderly nursing home patients (ages not stated) reported improved DCH following oral zinc supplementation (Ref. 31). Dietary zinc intake of the six subjects ranged from 6.8 to 13 mg per day. Subjects received oral zinc supplements of 15 mg zinc per day, as zinc gluconate, for 28 days. Plasma zinc and DCH responses were evaluated before and after the supplementation period. Serum zinc levels increased significantly with zinc supplementation (paired t-test, $p<.05$, $n=5$). Mean serum zinc, initially 98 micrograms per deciliter (μg per dL), increased to 102 μg per dL following zinc supplementation. Five of the subjects were tested for DCH responses to four test antigens. The number of positive responses increased significantly from a mean of 1.8 positive reactions per subject before zinc supplementation to 2.8 positive reactions per subject after zinc supplementation (paired t-test, $p<.05$, $n=5$). Nonsupplemented control subjects were not included. Of the six test subjects, one subject received liquid nutritional supplementation for weight gain, and one subject did not participate in DCH testing (Ref. 31).

In a study of immune function in zinc-deficient elderly subjects, Cossack (Ref. 32) selected eight zinc-deficient subjects from among 50 relatively healthy, low-socioeconomic status men age 65 to 78 years. Zinc deficiency was determined on the basis of "low status of zinc," subnormal DCH reactions, and low red blood cell (RBC) activity of a zinc-dependent enzyme (nucleoside phosphorylase) relative to normal values for healthy men of the same age. The zinc-deficient subjects received 60 mg zinc per day for 4.5 months, after which zinc concentration of plasma, RBC's, and white blood cells increased to normal values. The number of positive DCH responses to 4 test antigens increased from a mean of 2.1 positive responses per subject before supplementation to 3.1 positive responses per subject after supplementation. Zinc status and DCH reactions in the zinc-deficient subjects after zinc supplementation were comparable to the normal values determined for 13 healthy men of the same age (Ref. 32).

FDA believes that little weight can be given to these studies. The numbers of subjects in these four studies were quite small (eight or fewer subjects in three studies), providing little confidence in the results. Initial nutritional status of the institutionalized subjects, and reason for institutionalization, were not reported by Duchateau et al. (Ref. 29). Two of these studies (Refs. 30 and 32) were uncontrolled case reports on the effects of zinc supplementation of initially anergic or low zinc status elderly individuals selected from elderly populations surveyed for nutritional status and immunological indices. Similarly, the study of Soltesz et al. (Ref. 31) was uncontrolled and not blinded. Many potentially confounding factors in these studies were not considered or were not reported. Such factors include lack of dietary assessment, use of institutionalized elderly, and lack of monitoring for compliance with supplementation. Most importantly, the health significance, if any, of the findings of these studies with respect to enhanced resistance to disease is unknown.

Bracker et al. (Ref. 33) reported no effect of zinc supplementation on the antibody response to influenza vaccination. In this study, 41 healthy persons, age 64 to 90 years, were randomly assigned to supplemented (n=23; 50 mg oral zinc per day) or placebo (n=18) groups in a double-blind

2 month study. Subjects with diabetes, cancer, chronic renal disease, malabsorption, or senile dementia were excluded from the trial. Initial serum zinc was 80 ± 10 μg per dL, increasing to 116 μg per dL (mean value) in the supplemented group and 84 μg per dL (mean value) in the placebo group. Following the first month of supplementation, initial influenza antibody titres were measured, and trivalent influenza vaccine was administered. Influenza antibody titres were measured again following the second month of supplementation. No influence of zinc supplementation on post-vaccination increase of antibody titre was observed (Ref. 33).

Two recent well-controlled clinical studies by Bogden et al. (Refs. 34 and 35) failed to support the hypothesis that zinc supplementation can improve immunocompetence in the elderly. The first of these (Ref. 34) reports the findings of a double-blind, 3 month oral supplementation study of 103 apparently healthy, free-living persons, aged 60 to 89 years recruited from senior citizen centers in Bergen County, NJ. Subjects with a history of cancer, recent infectious disease, those on corticosteroid or estrogen therapy, or those using zinc supplements were excluded from the study. The subjects were randomly assigned to 3 groups: placebo (n=36), 15 mg zinc per day (n=36), and 100 mg zinc per day (n=31). All subjects received a daily multiple vitamin-mineral supplement without zinc in addition to oral zinc (or placebo) supplements. Compliance to supplementation was determined by a pill count at 3 months. A dietary questionnaire consisting of a food frequency checklist and a 24 hour dietary recall of the prior day's meals was also administered. The subjects consumed self-selected diets, providing an estimated average intake of 8 to 9 mg zinc per day. Plasma zinc increased from initial levels (84 to 86 μg per dL) in the group supplemented with 100 mg zinc per day but not in the placebo or 15 mg zinc per day groups. There were no changes from mean baseline zinc levels in RBC's, mononuclear cells, polymorphonuclear (PMN) cells, or platelets at 3 months in any group. There was a tendency for increased DCH responses after 3 months in all groups, and the increase was not different among groups.

Thirty study subjects, spread among the study groups, were initially anergic for DCH responses. The proportion of initially anergic subjects who developed positive DCH responses at 3 months was not different between placebo and zinc groups. In addition, there was no effect of zinc supplementation on in vitro LPR. In this study neither the cellular immunity nor zinc status, as indicated by cellular zinc content, of healthy elderly individuals with usual dietary zinc intakes of approximately 66 percent of the RDA, was enhanced by zinc supplementation (Ref. 34).

The second study (Ref. 35) followed the same double-blinded three group study design, with supplements provided for 12 months, after which all groups were switched to the placebo for an additional 4 months. Of 158 individuals initially enrolled, 63 subjects completed the entire 16-month study period, giving a response rate of 40 percent. The placebo group consisted of 24 persons. Twenty persons were included in the 15 mg zinc per day-supplemented group, and 19 persons were included in the 100 mg zinc per day-supplemented group. Dietary zinc intake (mean of 8.6 mg per day for males and 7.8 mg per day for females) from self-selected diets was similar among the three treatment groups and consistent over the course of the trial. Plasma zinc (initially about 85 μg per dL) increased only in the group taking 100 mg zinc per day and returned to baseline after zinc supplementation was discontinued. Monocyte, polymorphonuclear, erythrocyte, and platelet zinc levels were not altered, except for a transient increase of polymorphonuclear zinc in the 15 mg zinc per day group which returned to baseline at 12 months. DCH responses in all groups increased continuously over the study to about twice the initial values. The increase in DCH response was significantly greater in the placebo group than in either zinc-supplemented group. Furthermore, the suppression of the increased DCH response in the zinc-supplemented groups persisted 4 months after zinc supplementation was discontinued. The in vitro LPR increased during the study, particularly in the placebo group. There was a transient increase of T lymphocyte killer cell activity in the 100 mg zinc per day group, which did not persist beyond 3 months.

The authors speculate that the progressive increase of DCH response may be the result of a booster effect of repeated skin tests or a response to the multiple vitamin/mineral supplement administered to all subjects or to other unknown factors (Ref. 35). Except for a transient increase of natural killer cell function, this study did not show that zinc supplementation improved cellular immunity in the elderly. In fact, zinc at both doses appeared to have retarded improvement of cellular immunity. Lack of increased cellular (monocyte, polymorphonucleocyte, erythrocyte, and platelet) zinc levels with zinc supplementation suggests that the population was not zinc deficient, even though average dietary zinc intake was apparently well below the RDA (Ref. 35).

2. Other Relevant Information

a. *Physiological changes in aging.* Physiological changes of aging have effects on normal zinc metabolism and homeostasis, particularly the efficiency of intestinal absorption of zinc (Ref. 36). Average zinc absorption in six men aged 65 to 74 years and in six men aged 22 to 33 years was 17 percent and 31 percent, respectively (Ref. 36). This difference in zinc absorption between elderly and young men was significant. However, endogenous zinc losses in the elderly men were proportionally less than those in the younger men. There was no difference between young and elderly men in zinc balance. Lower zinc absorption in elderly men may reflect a lower requirement for zinc in the elderly. Homeostatic mechanisms also strongly influence zinc absorption. With decreasing zinc intake, the efficiency of intestinal zinc absorption increases, and excretion of endogenous zinc decreases. Thus the body is capable of adapting to variations in dietary zinc intake through increasing absorption and reducing endogenous loss (Ref. 36).

b. *Zinc status in the elderly.* The adult RDA (Ref. 25) for zinc is 15 mg per day for men and 12 mg per day for women. Differences in values for men and women reflect sex-related differences in body weight. The RDA is not a requirement below which deficiency diseases are apt to develop. Rather, for many nutrients, they are set at sufficiently high levels to cover the needs of practically all healthy individuals. Because individuals differ in their requirements for specific nutrients, it is impossible to know from a dietary survey which person requires at least the RDA and which one requires less or, in rare cases, possibly more. The intent of the RDA is to provide the basis for recommendations for healthy diets and for planning for the national food supply to improve the nutritional status of the population. It is not an appropriate use of the RDA to assert that adherence to the RDA will ensure protection against disease, or that intakes less than the RDA are necessarily inadequate or deficient (Ref. 25).

Dietary intake data are available from large national surveys such as the NFCS

conducted by the USDA and the NHANES II conducted by the National Center for Health Statistics (NCHS) (Ref. 37). NHANES III, which is currently in progress (1988 to 1994), will be the first NHANES to include sampling of the population older than 74 years of age. Other current data on nutritional status of older Americans comes from cross-sectional studies on relatively small selected samples.

Using the 1977 to 1978 NFCS and 1976 to 1980 NHANES II food consumption data bases, FDA's Total Diet Study designed diets to be representative of food intakes of men and women aged 60 to 65 years. Chemical analysis of the zinc content of these representative diets provided estimated average zinc intakes of 73 percent and 86 percent of the RDA for women and men, respectively, aged 60 to 65 years (Ref. 38). In smaller studies, dietary zinc intakes of institutionalized or house bound elderly people tended to be lower than those of free-living elderly persons (Refs. 16 and 17).

A recent review of studies of zinc intake by elderly individuals (Ref. 14) showed consistent average intake of 7 to 11 mg zinc per day. Two prospective zinc intervention studies of elderly subjects (Refs. 35 and 39) reported average dietary zinc intake of 8 to 9 mg per day which is consistent with other reports (Refs. 14 and 38).

It seems likely, from such studies, that some of the elderly in the United States consume less than the RDA for zinc. However, this finding does not necessarily imply that these elderly persons are consuming inadequate amounts of zinc. There is increasing evidence that these types of food intake estimates may underestimate food and nutrient intakes by significant amounts (Ref. 40). A more complete evaluation of problems of sensitivity and specificity of nutrient intake based on dietary recall data and the difficulty in predicting nutritional status from dietary data alone were described in a National Academy of Science report (Ref. 41).

Dietary data frequently estimate nutrients from foods alone. Contributions of dietary supplements are rarely considered but can provide significant quantities of zinc to total daily intake. The 1986 National Health Interview Survey showed that 38 percent of elderly Americans consumed over-the-counter vitamin and mineral products at least once during a 2-week period, with a median zinc intake of 100 percent of the RDA (Ref. 42). Another survey of elderly persons in the Boston area, found regular multivitamin-mineral use in 31 percent of males and 43 percent of females which supplied an average of 10 mg of zinc per day (males) and 9 mg zinc per day (females) (Ref. 43).

The best measures for determining nutritional status of human subjects are clinical and biochemical measures. Data on the nutritional status of the U.S. population have been collected in the NHANES. Results from NHANES II (1976 to 1980) were used to evaluate the prevalence of low serum zinc levels (defined as serum zinc less than 70 μg per dL for morning fasting blood samples) in the U.S. population (Ref. 44). The prevalence of low serum zinc levels was 3 percent in both males and females among the elderly (age 65 to 74 years). The prevalence across all ages was 1.3 percent for males, and an overall adjusted prevalence (excluding oral contraceptive users, pregnant, recently pregnant, and lactating women) of 2.1 percent was observed for females. Serum zinc reached peak levels in young adulthood (93 μg per dL in males; 85 μg per dL in females) and declined with age. Mean serum zinc levels for the elderly age group (65 to 74 years) were well within normal range (86 and 84 μg per dL for males and females, respectively). Poverty status was not associated with serum zinc levels in the elderly age group. Overall, blacks tended to have lower serum zinc values than did whites; however, there was no racial difference in serum zinc levels within the elderly age group (Ref. 44). Two prospective zinc intervention studies of elderly subjects (Refs. 35 and 39) also found mean serum zinc levels (about 86 μg per dL) to be within the normal range and consistent with NHANES data (Ref. 44).

An expert panel was convened to evaluate the usefulness of the serum zinc values from the NHANES II in determining the zinc nutritional status of the U.S. population (Ref. 44). This panel concluded that serum zinc values by themselves are not definitive for the assessment of zinc nutritional status because many factors besides zinc deficiency can depress serum zinc levels, e.g., stress/inflammatory response, albumin levels, diurnal variations, and meal consumption/fasting effects. In these cases, increasing zinc intake would not likely be effective in improving zinc status.

A recent report of the ad hoc Expert Panel on National Nutrition Monitoring, which reviewed data available through the National Nutrition Monitoring System of the USDA and DHHS, concluded that zinc is not a current public health issue to be assigned high priority, but that it does constitute a potential public health issue for which further study is needed (Ref. 45). The report also noted the discrepancy between apparently high percentages of people with moderate to low dietary intake and very small percentages of persons with low serum values. The Expert Panel on National Nutrition Monitoring recommendation for further research was made in recognition of the fact that the significance of the observed low dietary intakes of zinc cannot be evaluated without additional research to determine zinc requirements and to develop better measures of zinc status.

Zinc nutritional status is difficult to assess because of the lack of reliable noninvasive and specific methods and of the confounding of available measures of zinc status by factors unrelated to zinc insufficiencies. Thus the prevalence of poor zinc nutrition in the U.S. elderly is unknown. While zinc levels of blood cellular components has been proposed as a criterion for diagnosing mild zinc deficiency (Ref. 46), values for the general healthy elderly population in the United States are not currently available (Ref. 47). The high percentage (97 percent) of serum zinc values in the normal range for 65 to 74 year age group in the NHANES II do not provide compelling evidence of inadequate zinc nutriture in this population.

c. *Safety considerations.* The National Academy of Sciences in "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 24) and "Recommended Dietary Allowances" (Ref. 25) discussed potential health risks associated with oral zinc supplements. Considering the potential risks, these reports recommended against chronic ingestion of zinc supplements exceeding 15 mg per day (Refs. 24 and 25). Oral zinc supplementation at higher levels (e.g., 100 mg of zinc per day) is reported to suppress immune function (Ref. 48). Oral supplementation of 300 mg zinc per day was administered to 11 healthy males for 6 weeks. Subjects consumed self-selected diets providing an average of 11 mg per day. At 4 and 6 weeks several measures of immunocompetence were decreased (e.g., LPR and polymorphonuclear chemotaxis and phagocytosis). Other measures of immunocompetence (e.g., total number of lymphocytes, T cells, and B cells) were not altered during zinc supplementation. Duchateau et al. (Ref. 49), reported that zinc supplementation with 150 mg day for one month had a normalizing effect on LPR, increasing the response in individuals with initial low response but inhibiting LPR in individuals with initial values above the average.

Zinc intake in the range of 100 to 300 mg per day is reported to induce copper deficiency with attendant anemia, impaired immune function, and adverse effects on the low density lipoprotein/high density lipoprotein (LDL/HDL) cholesterol ratio (Ref. 25). There is also evidence that use of zinc supplements at lower levels (15 to 100 mg per day) may have adverse effects on copper balance and HDL-cholesterol which are similar to the problems of higher zinc doses (Refs. 9 and 50). Supplemental zinc ingestion, even at levels close to the RDA, appears to block the effect of exercise on raising serum HDL-cholesterol in elderly individuals (Ref. 51). The effect of zinc intake on lowering HDL-cholesterol has been confirmed in other reports (Refs. 48 and 52).

3. Conclusions

There are publicly available data for seven human studies in which elderly subjects were supplemented with zinc to determine the influence on immune system function. The earliest published study (Ref. 29) suggested a zinc-associated enhancement of several measures of immune function. Three additional studies in which a measure of cell-mediated immunity showed improvement with zinc supplementation selected initially anergic or zinc deficient subjects (Refs. 30 through 32). The results of the later studies are not relevant because they involved very few individuals, and the tested subjects were not representative of the general elderly population. The results discussed in these initial reports have not been substantiated by more recent, larger studies of more rigorous experimental design (Refs. 34 and 35). The later, larger studies showed no improvement of immunocompetence from zinc supplementation in the elderly. Furthermore, zinc supplementation at levels in excess of 100 mg per day can result in suppression of immune system function (Ref. 48). Thus, the publicly available data on the role of zinc in immune system function do not provide a sufficient scientific basis from which to conclude that immune function in the general elderly U.S. population can be improved by zinc supplementation.

Several comments requested that the agency also consider whether claims relating intakes of zinc by other age groups to improved immune function would meet the standard set forth in the 1990 amendments. Because of time and resource constraints, the agency did not broaden the scope of its considerations to include other age groups or nutrients. The 1990 amendments clearly identified zinc and immune function in the elderly as one of 10 specific topic areas for which the agency was to determine the validity of health claims.

In summary, proper dietary zinc levels are essential for adequate functioning of the immune system. Dietary zinc intake, serum zinc, and cell-mediated immunity all decline with advancing age. However, the available data do not provide a basis on which to conclude that increased zinc intake can reverse the age-related decline in immunocompetence in the general healthy elderly population in the United States. In fact, it may suppress immune function.

III. Tentative Decision to Deny a Health Claim Relating Zinc and Immune Function in the Elderly

The agency reviewed the publicly available scientific data and recent consensus documents on the association between the ingestion of zinc-containing supplements and immune system function in the elderly. The agency finds that the evidence provides no basis upon which to permit a health claim.

In 1988, the Surgeon General's report (Ref. 22) concluded that the available evidence was insufficient to determine if any age-related losses in immune function were caused by nutritional deficiencies. The human evidence that has become publicly available since the publication of that document does not provide adequate data to support a health claim relating the ingestion of zinc to improved immune system function in the elderly. Furthermore, the National Academy of Sciences publications, "Diet and Health" (Ref. 24) and "Recommended Dietary Allowances" (Ref. 25), raised safety concerns associated with oral zinc supplements. Finally, claims that zinc would prevent or treat any disease or health condition in the elderly would be a drug claim (FDA Health Fraud Bulletin No. 11, August 17, 1987).

The standard that FDA is proposing, in a companion document published elsewhere in this issue of the **Federal Register**, to apply to all foods is that there be significant scientific agreement that any health claim is supported by the publicly available evidence. For the topic of zinc and immune function in the elderly, the weight of the evidence is insufficient to support the claim, and there is no basis for scientific agreement that this claim is supported by the available evidence. Thus, the agency is proposing to add § 101.71(e) to deny the use on food, including dietary supplements, of health claims relating to an association between zinc supplementation and immune function in the elderly.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VI. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.71 is amended by adding new paragraph (e) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(e) Zinc and immune function in the elderly (insert cite and date of publication in the **Federal Register** of the final rule).

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

[Docket No. 91N-0103]

RIN 0905-AB67

Food Labeling: Health Claims and Label Statements: Omega-3 Fatty Acids and Coronary Heart Disease

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing not to authorize the use on foods, including dietary supplements, of health claims relating to the association between omega-3 fatty acids and coronary heart disease (CHD). FDA has reviewed the scientific data on this topic and has tentatively concluded this evidence does not provide a basis upon which to authorize such a health claim. Examination of the epidemiological research on this topic revealed that the available studies applied only to the consumption of fish, which contain omega-3 fatty acids, and that it was not possible to ascribe any effects specifically to the omega-3 fatty acids. Examination of data from clinical studies revealed that the effects on blood lipids of fish oils containing omega-3 fatty acids were primarily a reduction of blood triglycerides, a blood lipid variable not considered to be an independent risk factor for CHD, but they had no effect on serum cholesterol, low-density lipoprotein (LDL) cholesterol, or high-density lipoprotein (HDL) cholesterol, the blood lipid variables most closely associated with risk of CHD. The scientific data are ambiguous on the effects of omega-3 fatty acids on blood pressure and other risk factors for CHD. Finally, the scientific data reveal unresolved safety issues: the potential for omega-3 fatty acids to increase LDL cholesterol of hyperlipidemics and to worsen control of blood glucose in diabetics.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: John C. Wallingford, Center for Food Safety and Applied Nutrition (HFF-265), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-245-0835.

SUPPLEMENTARY INFORMATION:

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the Nutrition Labeling and Education Act of 1990 (Pub. L. 101-535) (the 1990 amendments), which amends the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary), and by delegation, FDA, to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under section 403(r) (i) (B) of the act (21 U.S.C. 343(r) (1) (B)).

Published elsewhere in this issue of the **Federal Register** is a proposed rule to establish general requirements for health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs, and other nutritional substances (referred to generally as "substances") to a disease or health-related condition on food labels and in labeling. In this companion document, FDA has tentatively concluded that such claims would only be justified for substances in dietary supplements as well as in conventional foods if it determines, based on its review of the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (section 3(b)(1)(A)(ii), (b)(1)(A)(iv), and (b)(1)(a)(x)) that within 12 months of enactment, the Secretary shall issue

proposed regulations to implement section 403(r) of the act (21 U.S.C. 343(r)), and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including omega-3 fatty acids and heart disease, meet the requirements of the act. The 1990 amendments defined the subject topic area as the relationship between omega-3 fatty acids and heart disease, without defining heart disease. For the purpose of this document, heart disease is considered to be CHD, defined in the International Classification of Diseases as ischemic heart disease and related diseases, most notably heart attacks (Ref. 33). In this document, the agency will consider whether a claim on food or food products, including conventional foods and dietary supplements, about the relationship between omega-3 fatty acids and CHD, would be justified under the standard and criteria proposed in the companion document entitled "Food Labeling: General Requirements for Health Claims for Food."

B. Public Health Aspects

1. Coronary Heart Disease

Cardiovascular disease (disease of the heart or blood vessels) is a major public health problem in the United States. Cardiovascular diseases, primarily CHD and stroke, kill nearly as many Americans as all other diseases combined. Cardiovascular disease is also among the leading causes of disability. These facts hold despite the fact that over the past 15 years, the death rate for cardiovascular disease has declined dramatically: 35 percent for all cardiovascular diseases, 40 percent for CHD, and more than 50 percent for stroke (Ref. 36). Changes in lifestyles, risk factor reduction, and medical intervention were major contributors to this decline (Ref. 36).

CHD (disease of the arteries supplying blood to the heart muscle) is generally considered to be the most common, the most serious, and the earliest form of cardiovascular disease, frequently producing symptoms and health problems in middle-aged adults (Ref. 115). Despite a declining death rate from CHD since the mid 1960's, CHD still accounts for more deaths than any other disease or group of diseases (Ref. 34). More than 1.25 million heart attacks occur each year (two-thirds occur in men), and more than 500,000 people die as a result (Ref. 34). Significant degrees of CHD without easily detectable symptoms are also very common in the United States (Refs. 36 and 37). Thus the total affected population is considerably higher than the statistics on death and illness would indicate. In addition to its impact on the nation's health, CHD costs the U.S. economy over $50 billion annually (Ref. 37).

Because of the importance of cardiovascular disease, including CHD, as a public health problem, identification of modifiable risk factors has received considerable research and public health policy attention since the early part of this century. Fatty streaks and cholesterol were identified many years ago as prominent components of the blood vessel (arterial) lesions whose buildup caused a narrowing or blockage of the blood flow to the heart (Ref. 36). Following those early observations, a large base of scientific evidence has accumulated on the relationship of different types of dietary fats to the risk of CHD. Based on the weight of the scientific evidence now available, virtually all recent dietary guidelines for Americans, whether from the Federal government or from the health profession community, have noted the high dietary fat intake by the U.S. population and also the strong association of diets high in fat, particularly saturated fat, and cholesterol with increased risk of CHD (Refs. 34, 36, and 115).

An elevated blood cholesterol level has been implicated as a factor in the development of atherosclerosis (inadequate circulation of blood to the heart due to narrowing of the arteries), a major contributor to CHD. In atherosclerosis, a buildup of solid material in and on the walls of blood vessels occurs that restricts the flow of blood. This material, referred to as "plaque," usually contains an appreciable amount of cholesterol.

For many individuals, there appears to be a correlation between the severity of the plaque deposits and the levels of cholesterol in the blood. Furthermore, it is now established that a particular fraction of blood cholesterol, that associated with LDL, conveys an increased risk of atherosclerosis, while cholesterol associated with a different lipoprotein, HDL, conveys reduced risk of atherosclerosis and CHD (see companion document on health claims for cardiovascular disease and lipids, published elsewhere in this issue of the **Federal Register**). The relationship between atherosclerosis and very low-density lipoproteins (VLDL), independent of LDL, is not clear (Refs. 35, 36, and 115].

There does not appear to be a strong relationship between atherosclerosis and blood triglycerides (another type of blood lipid, although not a fraction of blood cholesterol). Any relationship between blood triglycerides and CHD found in studies disappears once the blood cholesterol components known to be related to CHD are taken into account (Refs. 4, 35, 36, and 115). A National Heart, Blood, and Lung Institute consensus conference is planned for the beginning of 1992 to reexamine the relationship between blood triglycerides, HDL, and CHD. Many questions about the buildup of plaque remain unanswered, however, including why plaque deposits are formed and to what extent the consumption of individual dietary components influence blood cholesterol levels.

2. Omega-3 Fatty Acids

Omega-3 fatty acids are lipids (fats) consisting of polyunsaturated fatty acids with three or more double bonds. The differences between saturated fatty acids and unsaturated fatty acids are discussed in the document on nutrient content claims on fat, saturated fat, and cholesterol published elsewhere in this issue of the **Federal Register**. Their unique characteristic is the location of the first double bond, which occurs at the third carbon from the methyl (or omega) end of the fatty acid. The family of omega-3 fatty acids includes linolenic acid (18 carbons, 3 double bonds), which is found predominantly in plant oils, and eicosapentaenoic acid (EPA, 20 carbons, 5 double bonds) and docosahexaenoic acid (DHA, 22 carbons, 6 double bonds), which are found in fish and other marine animals. Linolenic acid is a precursor of the two longer chain omega-3 fatty acids. However, not all linolenic acid is converted to EPA or DHA. Omega-3 fatty acids cannot be synthesized in humans from other classes of fatty acids. Thus, they must be supplied by dietary sources.

The most common food source of longer chain omega-3 fatty acids is fatty fish, such as salmon and mackerel (Ref. 83). Another important dietary source of omega-3 fatty acids in the United States is chicken that have been fed fish meal. Bulk and encapsulated preparations enriched with omega-3 fatty acids are now available in the United States.

3. Relationship of Omega-3 Fatty Acids and CHD

Although polyunsaturated fatty acids other than omega-3 fatty acids may affect the risk of CHD, the 1990 amendments direct FDA to consider the relationship of omega-3 fatty acids to CHD (section 3 (b) (1) (A) (x) of the 1990 amendments). Most of the relevant research testing the hypothesis that omega-3 fatty acids reduce the risk of

CHD has been conducted using fish or fish oils rich in EPA and DHA because these particular fatty acids are known to have physiological effects. For this reason omega-3 fatty acids are defined as EPA and DHA in this document. Other omega-3 fatty acids related to EPA and DHA are not generally found in amounts as high as EPA and DHA, and their activity is thought to be via metabolism to EPA or DHA.

Two major mechanisms have been hypothesized for beneficial effects of omega-3 fatty acids, reduction in atherosclerosis and decreased formation of blood clots (thrombosis) either because of increased coagulation times or with concomitant increased dissolution of clots that may be formed.

Much of the data on omega-3 fatty acids has been collected in populations with risk factors for CHD, including high dietary saturated fat, hyperlipidemia (high blood cholesterol or triglycerides), high blood pressure, tobacco smoking, stress, and sedentary lifestyle.

A reduction in risk of CHD following consumption of foods that contain omega-3 fatty acids is not sufficient to support a relationship between omega-3 fatty acids and CHD, because foods that contain omega-3 fatty acids contain many other substances that may affect the risk of CHD. Furthermore, consumption of foods rich in omega-3 fatty acids may displace other foods from the diet that contain dietary components related to CHD. To establish a relationship between omega-3 fatty acids and CHD, any observed effect must be shown to be specifically from the specific omega-3 fatty acid component of the food.

C. Omega-3 Fatty Acids: Regulatory History

In the **Federal Register** of July 31, 1986 (51 FR 27461), FDA published a notice of the filing of a petition seeking affirmation that the use of menhaden oil and partially hydrogenated menhaden oil as direct human food ingredients is generally recognized as safe (GRAS). In the **Federal Register** of September 15, 1989 (54 FR 38219), FDA affirmed that hydrogenated and partially hydrogenated menhaden oil are GRAS (21 CFR 184.1472) for use as an edible fat or oil, as defined in 21 CFR 170.3(n) (12). The agency has not yet acted on the GRAS status of the use of nonhydrogenated menhaden oil.

In recent years, fish oil products bearing claims for beneficial cardiovascular effects appeared in the marketplace. In 1988, FDA issued regulatory letters concluding that claims for cholesterol-lowering properties of fish oil supplements were drug claims, and that the evidence did not support the claims (Ref. 45). In response, the industry contended that the claims on fish oil supplements were not intended to be drug claims but were intended to comply with FDA's proposed rule on health messages (52 FR 28843, August 4, 1987), subsequently withdrawn and reproposed (55 FR 5176, February 13, 1990). Although additional information was submitted in support of these health messages (hereinafter referred to as health claims), FDA informed the industry in 1990 that the additional data were not adequate to support the claims, because of the preliminary nature of the evidence and because of unresolved safety concerns (Ref. 46). In an advance notice of proposed rulemaking published in the **Federal Register** of August 8, 1989 (54 FR 32610), FDA requested comments on, among other things, how to reasonably permit the use of claims on food labels linking food components to the risk of chronic diseases. The agency did not, however, specifically mention the topic of omega-3 fatty acids and CHD.

D. Evidence Considered in This Review

The agency has reviewed all relevant scientific evidence relating to omega-3 fatty acids and CHD. The scientific evidence reviewed by the agency included recent comprehensive reviews and recommendations of the Federal government: "The Surgeon General's Report on Nutrition and Health" (Ref. 34); the National Institutes of Health's National Cholesterol Education Program (NCEP) Report on "Detection, Evaluation and Treatment of High Blood Cholesterol in Adults" (Ref. 35); and the NCEP Report "Population Strategies for Blood Cholesterol Reduction" (Ref. 36). Other comprehensive reports were also reviewed: the National Academy of Sciences 1989 Report "Diet and Health: Implications for Reducing Chronic Disease Risks" (Ref. 115); the 1986 FASEB report on "Review of the Epidemiological and Clinical Evidence on the Role of Omega-3 Fatty Acids in Health and Disease" (Ref. 83); the 1989 Mitre Report on "Health Effects of Refined Menhaden Oil" (Ref. 72); and the 1991 FASEB report on "Cardiovascular Effects from Omega-3 Fatty Acids" (Ref. 100). The agency updated the conclusions reached by these documents by reviewing all human studies published subsequent to these documents and all new review articles (Refs. 10, 21, 82, 84, 89, 91, 111, 112, 127, 161, and 162). However, surveys and cross-sectional or prospective studies, other than intervention studies, that had been published before 1988, which were used to generate the hypothesis of a relationship between omega-3 fatty acids and CHD, were also reexamined. Animal studies were considered to the extent that they clarified human studies or suggested possible mechanisms of action.

E. Comments Received in Response to FDA Request for Scientific Data and Information

To ensure that its review was complete, in the **Federal Register** of March 28, 1991 (56 FR 12932), FDA requested scientific data and information on the 10 topics, including omega-3 fatty acids and CHD, identified by section 3 (b) (1) (A) of the 1990 amendments. The agency received a total of 15 comments in response to this request. All relevant scientific information submitted was considered in the FDA scientific summary.

One comment was from a private citizen, who submitted a computer search of medical literature.

Three comments were from professional organizations, informing FDA of their position on health claims. A comment from the Association of Food and Drug Officials expressed concern that there be significant scientific agreement for any claim and enumerated steps to protect against unfounded claims. A comment from the Association of State and Territorial Public Health Nutrition Directors urged that the amount of nutrients in the total daily diet be an important consideration and expressed concern that labels might contain too much information to be helpful to the consumer. One comment from the American Health Foundation dealt with the relationship between omega-3 fatty acids and cancer. This comment is outside the scope of the rulemaking.

The Government of Canada stated that under Canadian law, proposed health claims regarding heart disease would be considered drug claims.

Ten comments (including one book) were submitted by professional or trade organizations for food/food supplement manufacturers or individual food or supplement manufacturers. One comment from a chemical manufacturer provided information regarding the requirement for vitamin E when supplemental omega-3 fatty acids are consumed. Three comments from manufacturers or distributors of dietary supplement products and one trade organization for dietary supplement products commented on approaches for regulating health claims. Five comments from trade organizations, food manufacturers, or manufacturers/

distributors of dietary supplement products described properties of omega-3 fatty acids and provided bibliographic information for scientific information of the topic. One supplement manufacturer provided a listing of proposals for research on omega-3 fatty acids and an unpublished paper on the utility of fish oils in providing dietary omega-3 fatty acids. One comment from a trade organization included a copy of proceedings of an international conference on the effects of omega-3 fatty acids on bleeding. No original data about the effects of omega-3 fatty acids on CHD were presented in any comment. The information submitted will be considered in the agency's discussion of the relevant scientific evidence.

II. Review of the Scientific Evidence

A. Federal Government Documents

"The Surgeon General's Report on Nutrition and Health" (Ref. 34) described studies that correlated increased fish intakes with reductions in risk of CHD, while noting that not all studies found a relationship. Regarding plasma lipids, the report stated that diets rich in omega-3 fatty acids:

> * * * generally showed variable reductions in total cholesterol and LDL cholesterol. In some cases, LDL increased; HDL levels were either unchanged or increased * * * The most consistent effect has been a reduction in triglyceride and VLDL.

The report acknowledged the significance of research into the relationship between omega-3 fatty acids and CHD but did not make any specific recommendations regarding the consumption of omega-3 fatty acids. Additionally, the report cautioned that the benefits in the cited studies had not been shown to be attributable to omega-3 fatty acid intake and could be from some other factor associated with fish consumption.

A similar position was taken by the NCEP of the National Institutes of Health (Ref. 35):

> * * * There is little evidence that omega-3 fatty acids are useful for reducing LDL-cholesterol levels. Although it has been postulated by some that they will reduce the risk for CHD, this has not been established. Furthermore, it is not known whether long-term ingestion of these fatty acids will lead to undesirable side effects. The use of fish-oil capsules as a supplement in a therapeutic diet for high-risk cholesterol levels is not recommended here * * *
> (Ref. 35, p. 33).

Furthermore, this NCEP document distinguished reported protective effects of fish consumption from alleged protective effects of omega-3 fatty acids from fish:

> * * * Consumption of omega-3 fatty acids should be differentiated from that of fish. Some fish are rich in omega-3 fatty acids while others are not. Epidemiological data suggest that frequent consumption of fish of any type, seemingly independent of omega-3 fatty acids, is associated with reduced CHD risk. Whether this is true or not, fish can serve as a useful substitute for meats that are richer in saturated fats. * * *
> (Ref. 35, p. 33).

The NCEP's Expert Panel on Population Strategies for Blood Cholesterol Reduction (Ref. 35) did not comment on the relationship between omega-3 fatty acids and CHD but like the two other reports above, noted that:

> * * * Supplementation of the diet with omega-3 polyunsaturates, without altering the intake of saturated fatty acids, does not cause a lowering of LDL-cholesterol, * * *
> (Ref. 35, p. 36).

"The Surgeon General's Report on Nutrition and Health" (Ref. 34) and the NCEP reports encouraged consumption of fish, but none found adequate evidence that omega-3 fatty acids could reduce the risk of CHD. Further, the NCEP Reports (Refs. 35 and 36) specifically did not recommend fish oil supplements and cited the lack of evidence of beneficial effects and long-term safety and undesirable side effects.

B. Other Reports

The National Academy of Sciences (NAS) Committee on Diet and Health noted that reports of low rates of CHD among Greenland Eskimos, which provided the basis for interest in a possible relationship between omega-3 fatty acids and CHD, were poorly documented. The NAS cited eight major reviews and numerous individual papers on the effects of omega-3 fatty acids on plasma lipids and lipoproteins and cited the indepth review of Herold and Kinsella (Ref. 67) on eicosanoid effects of EPA and DHA on hemostasis and on metabolism of omega-3 fatty acids. NAS concluded that:

> * * * Their [omega-3 fatty acids] effects on LDL cholesterol vary, and data on the long-term health effects of large doses on omega-3 polyunsaturated fatty acids are limited. Limited epidemiologic data suggest that consumption of one or two servings of fish per week is associated with a lower CHD risk, but the evidence is not sufficient to ascertain whether the association is causal or related to the omega-3 polyunsaturated fatty acid content of fish.

The NAS Committee went on to recommend that omega-3 supplements should not be used, stating:

> * * * Although consumption of fish one or more times a week has been associated with a reduced risk of coronary heart disease, the committee does not recommend the use of concentrated fish oil supplements, because there is insufficient evidence that they are beneficial and the absence of long-term adverse effects has not been established.

In 1986, FDA contracted with the Life Sciences Research Organization (LSRO) of the Federation of American Societies for Experimental Biology (FASEB) to review the evidence for the role of omega-3 fatty acids in health and disease (Ref. 83). The report concluded that fish consumption provided:

> * * * some degree of protection against the development of cardiovascular disease. Most studies have found an inverse relationship between fish consumption and coronary heart disease mortality. The omega-3 fatty acids in fish have been presumed to be responsible for these effects, but whether other compounds in fish may be involved remains to be determined.

The LSRO report also concluded that:

> * * * Clinical trials of the use of omega-3 fatty acids to reduce serum lipid levels in patients with various genetic and induced hyperlipidemias have generally been positive,

apparently meaning triglycerides and VLDL, given the full text of the report.

The LSRO report also cautioned that:

> * * * Animal studies indicate the potential for several deleterious effects. Toxicological evaluation of products containing these fatty acids, especially fish oil concentrate and derivatives, is needed.

FDA contracted for another report by the Mitre Corporation to define health effects of refined menhaden oil, a rich source of omega-3 fatty acids. This report (Ref. 72) identified major effects of omega-3 fatty acids as alterations in production of various bioactive compounds, increased bleeding (with particular concern for various bleeding conditions such as childbirth, ulcers, hemophilia, and menstruation), reduced platelet aggregation, and attenuation of inflammatory response. It also noted that effects on blood lipids other than triglycerides were not clearly established.

A second LSRO report contracted by FDA as part of FDA's information gathering effort divided the topic into six areas: Hypertension; thrombosis; the growth of the atherosclerotic plaque; hyperlipidemia and lipoprotein disorders; diabetes mellitus; and clinical trials in coronary patients. Brief synopses of selected scientific reports were presented in each section, followed by a summary of the full report and conclusions. LSRO concluded that there may be a decrease in total cholesterol and LDL concentrations without HDL being decreased but did

not explain how these conclusions were reached (Ref. 100). It concluded that there was an effect of omega-3 fatty acids on the development of the atherosclerotic plaque but cited only animal studies as evidence. It concluded that omega-3 fatty acids affect platelet function but did not provide evidence that the altered platelet function would or would not reduce the risk of CHD in humans. It described an effect of omega-3 fatty acids on blood pressure but did not distinguish between healthy and hypertensive subjects. Finally, it concluded that there was a basis in international epidemiological findings for a relationship between fish consumption and CHD but did not demonstrate that the omega-3 fatty acids in fish were the components responsible for the association.

In summary, omega-3 fatty acids were considered separately from total fat and polyunsaturated fat by the Federal government and other comprehensive reports, because these fatty acids may produce protective effects on CHD. None of these documents except the LSRO report found the evidence for a relationship between omega-3 fatty acids and CHD to be persuasive.

C. Review of the Scientific Literature

1. Evidence Reviewed

A number of human studies have been reported since publication of the Federal government and other comprehensive reports described above. FDA conducted a thorough review of the literature published between January 1988 and August 1991 and found numerous research papers directly and indirectly related to the topic.

The criteria that the agency used to select pertinent papers for its review were: (1) Presentation of primary data and adequate descriptions of study design and methodologies sufficient to allow an evaluation of the quality and relevance of the study, (2) availability in English, (3) a quantitative estimate of the amount of omega-3 fatty acids used, and (4) quantitative data on CHD or a marker associated with CHD. In general, FDA considered randomized, double-blind, placebocontrolled trials to be more valuable than other types of human studies because they were less susceptible to bias, and because they allowed inference about specific effects of omega-3 fatty acids.

Epidemiologic evidence for an association between omega-3 fatty acids and heart disease is of two types, descriptive and analytical. Descriptive epidemiology studies include correlational studies in which grouped population data are examined. Analytical epidemiology studies examine exposure and outcome in the same individual. These include cross-sectional studies in which dietary exposure (e.g., fish consumption) is measured at a single point in time and compared to a health outcome such as CHD, prospective studies in which dietary exposure is measured at the beginning of the study and the subjects are followed over time to compare exposure and health outcome, and intervention studies.

The criteria used in evaluating epidemiological studies included the following: (1) The reliability and accuracy of the methods used in food intake analysis and measurement of disease endpoints, (2) the choice of control subjects (e.g., hospital-based versus population-based), (3) the representativeness of subjects, (4) the control of confounding factors in data analysis, (5) the potential for misclassification of individuals with regard to dietary exposure or disease endpoints, (6) the presence of recall bias and interviewer bias, and (7) the degree of compliance and how compliance was assessed.

FDA evaluated the weaknesses and strengths of individual studies (see "Assessment" column of Tables 1 and 2). It then assessed the strength of the overall combined evidence (e.g., epidemiologic studies including clinical trials and animal studies), taking into account the strength of the association, the consistency of findings, specificity of the association, evidence for a biological mechanism, and presence or absence of a dose-response relationship. FDA's conclusions reflect the strength of the data and consistency of the results.

FDA considered encapsulated fish oils concentrated in omega-3 fatty acids to be a valid test material because such use provided some basis to find that the component responsible for observed effects was the omega-3 fatty acids. The agency also gave greater weight to studies in which compliance was documented with a biological marker of treatment, e.g., plasma or tissue phospholipid content of EPA and DHA, when measurements demonstrated internal validity of the study, and when the amount of omega-3 fatty acids in the total diet was assessed than to studies that were not as carefully done. FDA considered the level of dietary intake of omega-3 fatty acids used in a study, because the agency considered it important that if this substance is to be considered to be a food, intake levels should be consistent with an amount that could be consumed in a normal diet.

While FDA considered studies using healthy populations to be the most relevant to the issue, it also considered studies in subpopulations with CHD or risk factors for CHD. FDA extrapolated positive results from at-risk populations cautiously, however. While FDA assumes that the same mechanism of CHD risk is affected by omega-3 fatty acids in both high risk and generally healthy populations, the agency believes that the high risk population may be more sensitive to showing an effect. When it did make extrapolations, FDA considered it essential that data showing the same effect in the general population were also available.

FDA evaluated the weaknesses and strengths of individual studies reviewed (Tables 1 and 2). FDA then assessed the strength of the overall combined evidence (e.g., epidemiologic studies and animal studies) in light of five factors, strength of association, consistency of findings, specificity of the association, presence or absence of a dose-response relationship, and biologic plausibility of an association.

2. Epidemiologic Evidence

a. *Correlational and cross-sectional studies.* A protective effect EPA and DHA on the development of CHD was hypothesized based on data comparing rates of heart disease among Greenland Eskimos and Danes (Ref. 39). Greenlanders residing in Greenland had approximately tenfold lower death rates from ischemic heart disease than Greenlanders who had migrated to Denmark. Dietary factors were hypothesized to explain this difference. Compared to immigrant Greenlanders living in Denmark, those living in Greenland consumed comparable amounts of total fat but ate less than half the saturated fat; over 50 percent more monounsaturated and polyunsaturated fat; and nearly five times the amount of omega-3 fatty acids. However, since whale blubber and seal (also sources of omega-3 fatty acids) were consumed by the Greenlanders much more frequently than fish, components of the Eskimo diet other than omega-3 fatty acids may be important determinants of CHD risk.

Three studies found an inverse relationship between fish consumption and CHD, from rural Japanese, urban Japanese, Japanese Americans, and Caucasian Americans (Ref. 76) and among various Japanese communities (Refs. 68 and 75).

However, other similar studies have not found a relationship between fish consumption and CHD. An international correlational study found only a modest association between fish consumption and CHD mortality across widely

different populations (Ref. 23), and when other dietary variables were controlled, the relationship was no longer apparent. CHD mortality in two provinces in Canada was not correlated to per capita fish intake in those provinces (Ref. 74), nor was a correlation found in two Norwegian communities (Ref. 141) with different fish consumption.

b. *Prospective studies.* A prospective study of 852 men found that an average consumption of 30 grams (g) of fish per day over a 20-year period reduced the risk of CHD by more than 50 percent (Ref. 87). Two reports from the United States also found a beneficial effect attributable to fish consumption (Refs. 38 and 137).

Other studies in Honolulu (Ref. 25) and Norway (Ref. 158) did not find any relationship between fish consumption and risk of CHD. Also, a study from Sweden (Ref. 113) reported an effect, but it was not statistically significant. These nonintervention epidemiologic studies are summarized in Table 1.

One type of evidence that would support a causal relationship between two factors is a dose-response relationship, where the degree of effect of an active component is related to the amount of the component. In those studies that reported a protective effect of fish consumption on CHD, each found the effect was related to the amount of fish consumed (Refs. 87 and 137). One study related the risk to the calculated amount of omega-3 fatty acids in the diet (Ref. 38). The effect of fish consumption on CHD is seen with small amounts of fish (i.e., about 30 g per day (g/day)), and therefore, small amounts of omega-3 fatty acids (Ref. 88). The results from these studies are viewed by FDA as ambiguous. Not all the studies found a relationship between consumption of fish containing omega-3 fatty acids and CHD. Only one study related the protective effect to the calculated amount of dietary omega-3 fatty acids rather than to consumption of fish (Ref. 38). Other dietary variables known to be related to CHD were also correlated with fish consumption in these studies. For example, in the prospective study of 852 men (Ref. 87), a number of other dietary variables that may indepen dently be related to the risk of CHD were also related to fish consumption. In this study, men who consumed the largest amounts of fish also consumed significantly more alcohol and monounsaturated and polyunsaturated fatty acids than men who did not eat fish. Thus, dietary factors associated with fish intake other than omega-3 fatty acids may account for the observed positive correlations.

Furthermore, the estimated content of omega-3 fatty acids in the amount of fish reported to be protective against CHD is very low, so low that their level calls into question whether the omega-3 fatty acids in fish are the component responsible for the reported protective effect. Also, the dose-response relationships reported differ somewhat. In Kromhout et al. most of the reduction in risk occurred when only 1 to 14 g/day of fish were consumed (about 0.3 g EPA plus DHA) (Ref. 87). In contrast, the study that related CHD risk to estimates of omega-3 fatty acids consumed (rather than fish) found the effect was pronounced only among those who consumed the greatest amount of omega-3 fatty acids, 0.66 g/day on average (Ref. 38).

Finally, in the studies in which 20- or 25-year mortality from CHD was related to fish consumption (Refs. 87 and 137), dietary data were collected only during the first year of the study. Thus, these studies do not distinguish between a protective effect of fish consumption at an early point in life and an effect from chronic fish consumption. The shorter duration followup Multiple Risk Factor Intervention Trial (MRFIT) study estimated dietary consumption from 24-hour recall data collected approximately yearly over the 6-year followup and supports that continued consumption of omega-3 fatty acids, rather than simply early life consumption of fish, has a protective effect (Ref. 38).

Overall, these studies are considered to be ambiguous because they are not capable of distinguishing the effects that are specific to omega-3 fatty acids from those that are related to fish consumption.

c. *Intervention studies.* Although experimental trials are considered to be the most useful to infer causal relationships, only one study of this type has been completed on omega-3 fatty acids and CHD (Ref. 16). The study was conducted among 2,033 male survivors of previous heart attacks who were advised to increase their consumption of fish and of fiber and to decrease fat intake. All combinations of these three types of advice were given. Another group, serving as a control, received no advice at all. Mortality was assessed over the following 2 years. Those subjects who were advised to increase fish consumption had a 29 percent lower death rate, attributable entirely to deaths from CHD, than subjects advised to increase fiber or decrease fat consumption but not advised to increase fish consumption. However, the rate of occurrence of a second heart attack was not different between the fish-advice and nonfish-advice groups. Fish consumption was measured by a dietary questionnaire in a subset of subjects in the fish-advice group. The amount of fish reported by Burr et al. to be protective was modest, approximately 200 to 400 g fish per week (Ref. 16).

Some (14 percent) of the men at 6 months into the trial, and more (22 percent) at the end of the 2-year trial, consumed encapsulated fish oil rather than the prescribed amount of fish (300 g per week, or about 2.5 g EPA per week). However, separate data for the fish consumers and fish oil consumers were not presented, so the effects of fish oils cannot be compared to the effects of fish consumption. No dose-response analysis was performed, and no biochemical data were reported documenting the ingestion and incorporation of omega-3 fatty acids. Data were not reported on the effects of advice about fish consumption on markers of CHD, i.e., serum cholesterol (although it was noted that the fish-advice group had increased total serum cholesterol at 6 months and unchanged total cholesterol after 2 years), making it difficult to put the results of this study into context of other studies reporting similar data.

3. Evidence Relating Omega-3 Fatty Acids to Intermediate or Surrogate Markers of CHD

Most information about the effects of omega-3 fatty acids on CHD has been derived from clinical trials using concentrated fish oils enriched in EPA and DHA and, in some cases, in purified methyl or ethyl esters of EPA and DHA. These studies have not measured occurrence of heart attack or CHD death as an endpoint but instead used surrogate markers for CHD, e.g., serum lipids, blood pressure, measures of clotting, and clot dissolution. While these markers are limited in their ability to predict CHD, they are easily measured and provide important information about intermediates in the disease processes. The amount of omega-3 fatty acid intake in studies using fish oils is usually greater than the amount of omega-3 fatty acids in fish diets associated with reduced risk of CHD.

The clinical effects of omega-3 fatty acids from fish oils are generally evaluated relative to two categories: Effects on atherosclerosis and on blood lipids closely correlated with atherosclerosis, and effects on thrombosis (aggregation of blood platelets and fibrin leading to blood clot formation) and hemostasis (the arrest of bleeding). However, there are other potential effects of omega-3 fatty acids

that could affect risk of CHD that also require evaluation, e.g., whether omega-3 fatty acids reduce blood pressure. Table 2 is a summary of data from clinical trials published since 1987.

a. *Atherosclerosis*—i. *Blood lipids.* The effects of fish oils and high fish diets on blood lipids have been studied because such effects, if demonstrated, would represent a mechanism by which omega-3 fatty acids could reduce risk of CHD. Although some studies of high fish diets reported reductions of serum cholesterol and LDL and VLDL cholesterol, these studies also involved substantial changes in other components of the diet, primarily the replacement of saturated fat with unsaturated fat (Refs. 17, 62, and 117). Thus, the effects could not be definitively attributed to omega-3 fatty acids. Most recent studies have used fish oil supplements containing omega-3 fatty acids rather than fish and have used a placebo containing alternate polyunsaturated fatty acids in an attempt to avoid confounding effects of other diet components.

The predominant blood lipid effects of fish oils in normal subjects, in subpopulations with diseases or medical conditions associated with increased risk of CHD, and in subjects with diagnosed CHD are decreased plasma triglycerides and VLDL which is rich in triglyceride and cholesterol. However, these blood lipids are not generally considered independent risk factors for CHD (Refs. 35, 36, and 115). The effects on total cholesterol, LDL cholesterol, and HDL cholesterol have been variable.

Most studies of normal, healthy adults show no significant effect that can be specifically attributed to fish oil on serum total cholesterol, LDL, or HDL cholesterol (Refs. 9, 14, 15, 17, 20, 24, 31, 43, 48, 49, 53, 54, 59, 73, 98, 99, 104, 109, 146, 150, 156, and 166). Only four of these studies were carried out in a randomized, double-blinded, placebo-controlled design (Refs. 6, 24, 54, 73, and 166), although other studies either randomized the subjects (Refs. 9, 14, 49, and 54) or matched test subjects and controls (Refs. 15, 20, 31, and 156). Some used a crossover design (Refs. 14 and 17). Some studies reported no effects of fish oils or used relatively small numbers of subjects, and may not have had sufficient statistical power to detect a difference (Refs. 15, 24, 31, 48, 59, 99, 104, and 146). Two studies used fish as the source of omega-3 fatty acids (Refs. 17 and 156) which does not provide a basis on which to separate the effects of omega-3 fatty acids from the effects of other components of fish or on which to separate the effects of polyunsaturated fatty acids from the effects of omega-3 fatty acids. The studies ranged in duration from only 3 weeks of treatment to 12 weeks.

The studies with the most rigorous design and largest number of subjects found that supplementation with fish oils, or increasing dietary fish consumption, resulted in decreased blood triglycerides among normal, healthy subjects (Refs. 9, 49, 54, and 156). The only studies among normal subjects where no decrease in triglycerides was found either used very small doses in a small numbers of subjects (Croset et al. 1990 used 100 mg EPA/d in 8 subjects; Lox 1990b used 900 mg EPA plus DHA/d in 9 subjects), or the decrease was marked but not statistically significant (Refs. 99 and 73).

The studies with the most rigorous design and largest number of subjects also found that there was no effect of fish oils on total serum cholesterol (Refs. 6, 9, 14, 49, 54, 73, and 166). The only study reporting decreased total cholesterol fed 30 to 40 percent of calories from fish oil, confounding effects of omega-3 fatty acids and polyunsaturated fatty acids (Ref. 59).

These same studies found no change in LDL cholesterol, except that Fumeron et al. (1991) reported increased LDL cholesterol. Similarly, most studies did not find a significant effect on total HDL cholesterol (Refs. 6, 9, 14, 31, 54, 73, and 166). Flaten et al. (1990) and Takimoto et al. (1989) reported a decrease in total HDL cholesterol at 6 weeks of supplementation, but these studies used relatively high doses (7.7 g EPA plus DHA/d and 8.2 g EPA plus DHA/d, respectively). Neither study controlled for polyunsaturated fatty acids. Compared to saturated fat diets, fish diets may reduce HDL cholesterol (Ref. 17), although an increase in HDL cholesterol was reported after fish paste, compared to meat paste supplements, were added to the diet (Ref. 17). Some investigators (Refs. 9 and 54) have reported that supplementation with fish oils increased HDL_2 cholesterol, the particular subfraction of HDL that is most closely related to decreased CHD risk (Ref. 3), whereas others found no change (Refs. 14 and 49).

Data have also been reported on the apoproteins associated with LDL (apoB) and with HDL (apoA), in contrast to the cholesterol associated with these lipoproteins. No effect of fish oils has been found (Refs. 6, 54, and 73). Although there are fewer data reported, it appears that apoprotein components of lipoproteins respond in the same manner as the cholesterol component, i.e., lower after feeding polyunsaturates, including fish oils, than after a saturated fat diet (Refs. 43 and 53).

Thus, except for a study in which very large amounts of fish oils were fed, recent studies have not found fish oils to modify total serum cholesterol, LDL cholesterol, HDL cholesterol, or the apoproteins associated with these lipoproteins in normal subjects. The possibility of a selective increase by fish oils containing omega-3 fatty acids of HDL_2 (a fraction of HDL) cholesterol, which is inversely related to CHD, is the most promising change in blood lipids yet reported, but the data reported to date are equivocal.

There have been many studies recently on the effects of fish oils on serum lipoproteins among hyperlipidemic subjects (people with elevated blood cholesterol with or without elevated triglycerides), hypertriglyceridemic subjects (people with high blood triglycerides), and subjects who already have CHD. Most of these studies had strict designs, including randomization with or without crossover, blinding, and placebo treatments (Refs. 26, 29, 43, 61, 63, 80, 105, 114, 119, 121, 129, 140, 150, 164, and 166), but similar results were found in less rigorously controlled studies (Refs. 28, 60, 107, 130, 146, and 148). As in normal, healthy persons, the most reproducible effect of fish oils containing omega-3 fatty acids in these subpopulations is a decrease in serum triglycerides with the most marked reductions for those subjects with highest starting values. In addition, in common with the results in normal subjects, most studies in hyperlipidemics found no change in total serum cholesterol. In contrast to normal subjects, however, most studies on hyperlipidemic subjects reported an increase in LDL cholesterol following fish oil supplementation (Refs. 26 (for males), 60, 61, 63, 80, 94, 114, 119, 121, 130, 140, 146, 164, and 166), although a few found no change compared to olive oil (Refs. 29, 105, and 107) or may not have had sufficient statistical power to detect a difference (Ref. 43). One reported a decrease (Ref. 148). The level of apoB has also usually been found higher after fish oil consumption (Refs. 29, 43, 60, 61, 133, and 140). HDL cholesterol is usually reported as not changed (Ref. 114), but some increases and decreases have been reported (Refs. 26 (males), 29, 63, and 130). Takimoto et al. (1989) and Radack et al. (1990) reported lower HDL_2 cholesterol.

ii. *Vessel wall effects.* Another way that omega-3 fatty acids could affect the process of atherosclerosis is through

changing the way cells of blood vessels respond to factors that promote atherosclerosis. The cells of blood vessels produce compounds from omega-3 fatty acids that have many functions related to the health of the blood vessel (Refs. 41, 48, 160, also see animal studies in Refs. 50, and 138). Some of these functions are keeping the muscle cells of the blood vessel wall relaxed, keeping the vessel elastic and pliant, and dissolving small blood clots attached to blood vessels. An increase in consumption of omega-3 fatty acids results in increased production of the compounds that relax or dilate the vessel wall at the same time that they decrease the formation of compounds that constrict the vessel wall (Ref. 28).

Through the compounds they form in the blood vessel wall, omega-3 fatty acids may prevent the infiltration of certain white blood cells, called monocytes, into the vessel wall, and monocytes themselves produce compounds that increase the inflammatory process (Refs. 82 and 162). Recent studies reported that white blood cells taken from normal men and hyperlipidemic men who consumed fish oil containing EPA plus DHA at levels as low as 1.3 g/day for 6 weeks have a reduced chemotactic response, i.e., they are not as strongly attracted to stimulants (Refs. 135 and 136).

An area studied recently is the effect of fish oils on restenosis, that is, the reclosing of a vessel after mechanical opening. Although the use of omega-3 fatty acids in this context is clearly a drug usage, these studies have been cited as evidence of the role of omega-3 fatty acids in the maintenance and normalization of vessel function. One study found reduced rates of restenosis when fish oil was given in addition to two other anticoagulant drugs beginning about the time the subjects underwent angioplasty (the term for the procedure used to open the vessel) (Ref. 30). However, this study was not blinded, and the results are limited to fish oil used in combination with other drugs. Other studies where double-blind conditions were maintained, where placebo controls were used, and where restenosis was confirmed by angiography, show no effect of fish oils (Refs. 56, 106, and 120).

In summary, the recent data on blood lipid responses of persons and among groups at high risk of CHD do not support the use of omega-3 fatty acids to reduce the risk of CHD. There is no effect of omega-3 fatty acids on blood cholesterol, LDL cholesterol, or apoB or apoA, and the effect on HDL cholesterol is ambiguous. There is very little data on the effects of omega-3 fatty acids on blood vessel integrity in humans, and it has not been established whether the type and magnitude of effects of compounds produced from omega-3 fatty acids results in a reduced risk for CHD.

b. *Thrombosis and hemostasis.* The other primary area in which omega-3 fatty acids may affect the risk of CHD is through their hypothesized effect on the formation and dissolution of blood clots (thrombosis and hemostasis). A decrease in clot formation, or an increase in the breakdown of clots, is generally believed to help prevent CHD deaths.

i. *Bleeding times.* One effect of omega-3 fatty acids is an increase in the time it takes for a small cut to stop bleeding. Bleeding times are often used as an indicator of the balance between necessary clotting (to prevent excessive bleeding) and excessive clotting (which may occlude blood flow). Increased bleeding times were observed among Greenland Eskimos by Dyerberg and Bang (Ref. 39) and were interpreted to be one of the reasons these people had reduced CHD risk. Many studies since have reported that fish oil supplementation increases bleeding times in normal subjects (Refs. 98 and 166) and in subjects either with risk factors for CHD or with diagnosed CHD (Refs. 28, 59, 95, 144, 145, and 166). However, some of these studies used quite high doses. Harris et al. used 28 g EPA plus DHA/d (Ref. 59). Levinson et al. used 50 milliliter (mL) maximum EPA or 18 g EPA plus DHA/d or used anticoagulants concurrently (Ref. 144). Others reported no effect (Ref. 57).

The bleeding time increase with fish oils is additive with increased bleeding following aspirin (Ref. 64). However, most reports suggest that serious bleeding is not an issue in patients supplemented with omega-3 fatty acids from fish oils even when fish oils were used in conjunction with aspirin (Refs. 22, 28, 56, 106, and 144). One recent review concluded that bleeding times are not correlated with serious bleeding (Ref. 125).

ii. *Platelet aggregation.* Another measure of clotting affected by omega-3 fatty acids is the aggregation of platelets, blood components that initiate clotting. This is an important area of study because spontaneous platelet aggregation has been reported to be inversely related to occurrence of heart attacks and CHD deaths in a population of survivors of a heart attack (Ref. 152). Platelet aggregation is generally considered to be decreased by fish oil consumption (Refs. 67, 70, 86, 159, and 162 for reviews; also in normal subjects see Refs. 2, 6, 24, 54, 96, 143, and 166). There were two studies among normal healthy subjects that found no effect (Refs. 73 and 150), but that result may be attributable to the small sample size. Reduced platelet aggregation has been reported for diseased populations (Ref. 28), except that there are other studies in which no effect was found (Ref. 93 through 95, and 134), possibly because of small numbers of subjects.

Other measures of platelet function, e.g., platelet activation, adhesiveness, and survival, are also affected by fish oils. Fish oil reduces platelet activation and adhesiveness and increases platelet survival (Refs. 94, 96, and 144).

Also, other blood-related properties besides platelets are affected by fish oils. Red blood cell deformability is increased and blood viscosity is decreased after consumption of fish oils (Refs. 18, 42, 145, and 160), which may affect the consequence of formation of small clots.

The relationship between platelet aggregation and the risk of heart attacks or CHD death in the general population is an important line of evidence that would support drug claims and perhaps health claims for omega-3 fatty acids. Although there is some evidence that changes in platelet aggregation may help prevent second heart attacks (Refs. 66 and 112), it has not been shown that changes in platelet aggregation in the general population will reduce the risk of CHD. The importance of other platelet or blood effects of omega-3 fatty acids on risk of CHD also has not been established.

iii. *Regulators of bleeding.* Markers for CHD other than cholesterol and blood lipids have also been found. One is the level of a plasma protein called fibrinogen, which is involved in blood clotting (Ref. 102). The effects of fish oils containing omega-3 fatty acids on fibrinogen were evaluated in 10 studies. One study had no control (Ref. 134), and one was confounded by concurrent anticoagulant therapy (Ref. 144). One compared fish paste to meat paste, so the effect of omega-3 fatty acids cannot be distinguished from other components in fish (Ref. 40). Among the remaining seven studies, six were randomized studies and one was a matched, controlled study. Four found a significant reduction in fibrinogen levels compared to olive oil (Refs. 49, 71, and 117) or soybean oil (at a high dose of omega-3 fatty acids only, not at a low dose, Ref. 57). One study found reduced fibrinogen in the group fed fish but not in the group fed fish oil (Ref. 20), raising the possibility that components of fish

other than the omega-3 fatty acids were responsible for the effect. In the remaining two studies, no effect was found compared to a corn oil placebo (Refs. 11 and 118), and one study showed that both corn oil and fish oil reduced fibrinogen comparably (Ref. 118), suggesting that the effect was produced by polyunsaturated fatty acids, not specifically omega-3 fatty acids.

Similarly, no clear relationship between omega-3 fatty acids and factors involved in dissolving blood clots has emerged (Refs. 29, 104, 150, and 131). Finally, a particular component of one of the lipoproteins, lipoprotein (a) is also considered a marker for atherosclerotic disease by its regulation of fibrinolysis, but the effects of omega-3 fatty acids on lipoprotein (a) have only been reported in abstracts.

iv. *Blood pressure.* One of the most consistently reported effects of omega-3 fatty acids from fish oils is a decrease in blood pressure. Among normal healthy subjects, reductions have been reported for systolic blood pressure (Refs. 6, 24, 49, and 80); reductions in diastolic blood pressure have not been significant (except Haglund et al. 1990, but the data for Haglund et al. 1990 are confounded because separate data were not reported for healthy subjects and subjects with CHD (Ref. 57)). One study among normal, healthy men showed that a mixed dietary supplement containing fish oil reduced systolic blood pressure, whereas no effect was seen when the supplement contained linseed oil or safflower oil (Ref. 80). Other studies in normal, healthy adults found that the reduction in blood pressure following consumption of fish oils was comparable to the reduction after consumption of other polyunsaturated oils (Refs. 20 and 49) or found no significant change after consumption of fish oils (Refs. 9 and 73).

In one report of a study of hypertensives (Ref. 11), a moderate dose (5.1 g/day) of purified ethyl esters of EPA and DHA for 10 weeks reduced blood pressure proportionally to the increase in plasma omega-3 fatty acids. Interestingly, no effect of fish oil was found among those subjects who habitually consumed three or more meals of fish per week. Controlled studies among hypertensives and among diabetics found reductions in both systolic and diastolic blood pressure (Refs. 11, 77, 85, 101, and 147). Very high amounts of fish oil (50 mL/day) were used in two of these studies (Refs. 85 and 95), and the placebo in one study was olive oil, not a high polyunsaturated oil (Ref. 77), so it is not clear if the effect of fish oil was because of polyunsaturated fatty acids or omega-3 fatty acids.

Whether the magnitude and duration of any decrease in blood pressure persist after longer term consumption of omega-3 fatty acids is not known. The longest duration of supplementation in the above studies was 12 weeks.

These results for effects of omega-3 fatty acids on blood pressure of normal subjects are ambiguous. Some studies found a reduction in systolic blood pressure after consumption of fish oils containing omega-3 fatty acids, whereas others did not. None of the studies found a significant reduction in diastolic blood pressure. Therefore, it also remains to be established that the normal, healthy population will reduce their risk of CHD via a reduction in blood pressure following consumption of omega-3 fatty acids.

In summary, there are a few established effects of omega-3 fatty acids from fish oils on thrombosis and hemostasis. Standardized bleeding times are increased, and platelet aggregation and function are reduced. However, direct relationships between the changes in bleeding times or platelet function and risk of CHD have not been established. While there is an established relationship between blood pressure and CHD, it has not been shown that omega-3 fatty acids specifically affect blood pressure in normal subjects in a way that would provide a protective benefit toward the risk of CHD. Effects of omega-3 fatty acids on other markers linked with CHD, e.g., fibrinogen or lipoprotein (a), have not been established.

4. Other Relevant Information

a. *Animal studies.* Animal studies, where the atherosclerosis may be measured directly, provide some evidence of an anti-atherogenic effect for omega-3 fatty acids. Studies in rabbits (Refs. 65 and 165), pigs (Ref. 81), rhesus or African green monkeys (Refs. 27 and 116), and dogs (Ref. 90) reported that incorporation of omega-3 fatty acids in a diet designed to promote atherosclerosis actually reduced development of atherosclerotic disease. However, other animal studies showed no reduction, or an increase, in atherosclerotic disease after dietary supplementation with omega-3 fatty acids (Refs. 19, 47, 51, 69, 97, 122, 123, 126, and 151). Thus, there are some data from studies in animals which suggest the possibility of a beneficial effect of omega-3 fatty acids on CHD, however, the data are equivocal.

b. *Safety considerations.* Trials of the effects of fish oils containing omega-3 fatty acids among diabetics show that total cholesterol, LDL cholesterol, or apoB may increase (Refs. 7, 77, 79, 108, 110, and 128). While some studies among insulin-dependent diabetics found no significant effect of fish oils on the ability to maintain desired levels of blood glucose (Refs. 77 and 124), others reported impaired glucose control (Ref. 55). Other studies on noninsulin-dependent diabetics reported that fish oil resulted in increased-blood glucose (Refs. 44, 52, 128, and 130). Adverse effects on blood glucose control have been reported for subjects who were both hypertriglyceridemic and diabetic, either insulin-dependent (Ref. 94) or noninsulin dependent (Ref. 146). In one study there was an increase in the blood triglyceride level over and above the initial level after fish-oil supplementation was discontinued (Ref. 124). Thus, use of fish oils containing omega-3 fatty acids may pose particular additional risks among diabetics, regarding both serum lipids and glycemic control.

III. Tentative Decision not to Authorize a Health Claim Relating Ingestion of Omega-3 Fatty Acids to Reduced Risk of Coronary Heart Disease

In evaluating the scientific evidence, FDA considered the strength of association of omega-3 fatty acids with CHD or surrogate markers for CHD, the consistency of findings among the many studies, the specificity of the outcome to omega-3 fatty acids, the presence or absence of a dose-response relationship, and biologic plausibility of an association.

FDA has determined that there is inadequate evidence to show that increased consumption of omega-3 fatty acids will reduce the risk of CHD. Furthermore, the review of scientific information reveals potential serious safety concerns about the use of fish oils containing omega-3 fatty acids by subpopulations who are at increased risk for CHD.

FDA attempted to determine whether there was significant scientific agreement among experts that the totality of publicly available scientific evidence supported the claim that omega-3 fatty acids reduce the risk of heart disease. FDA reviewed the position taken in numerous Federal government and other authoritative scientific reports and evaluated the totality of publicly available scientific evidence that has become available since those reports were written. The tentative decision to deny a health claim is based on the conclusions reached

following review of these various sources of information and conclusions.

"The Surgeon General's Report on Nutrition and Health," the National Academy of Science's Report on "Diet and Health: Implications for Reducing Chronic Disease Risk," and the National Cholesterol Education Program's "Detection, Evaluation and Treatment of High Blood Cholesterol in Adults" each concluded that there was inadequate evidence of a relationship between consumption of omega-3 fatty acids and CHD. FDA has rereviewed all the relevant cross-sectional data from which a relationship between omega-3 fatty acids and CHD was hypothesized, and all clinical intervention data published since these Federal government and other authoritative reports documents to determine whether the additional evidence is adequate to support a health claim for omega-3 fatty acids.

The LSRO report reached a different conclusion than the other authoritative reports by finding a relationship between omega-3 fatty acids and CHD. The report used only selected evidence, much of it from animal experiments with no clinical counterpart. Furthermore, it did not distinguish between the normal population and diseased subpopulations. Finally, it relied on international epidemiologic findings of a relationship between fish consumption and CHD that was not shown to be specific to omega-3 fatty acids.

The surveys, cross-sectional studies, and non-intervention prospective studies do not support a relationship between consumption of omega-3 fatty acids and CHD. Only a few studies found an association between fish intake and CHD, while others have found no association. Thus, there was not consistency of findings. None of the studies that reported a relationship distinguished fish consumption from other factors associated with fish consumption, and therefore they did not demonstrate specificity. Even in those studies reporting a relationship between fish consumption and CHD, it was not clear that the effects were because of the omega-3 fatty acids in fish. Also, the omega-3 fatty acid content of the fish diet associated with reduced CHD was so low that the importance of omega-3 fatty acids is questionable, i.e., calling into question the biologic plausibility of the relationship.

The data from intervention studies also do not establish a relationship between omega-3 fatty acids and risk of CHD. The most compelling type of evidence to support a diet-disease relationship is a prospective, double-blinded, placebo-controlled intervention study, using CHD morbidity and mortality as endpoints. To date, there is only one such trial (Ref. 16). The results of that study showed that increased consumption of fish does not reduce the risk of a second heart attack but may reduce the risk that the attack will be fatal. However, as with the nonintervention study data, this study did not provide evidence to attribute the benefit to omega-3 fatty acid intake rather than some other factor associated with fish consumption (specificity). Furthermore, no data were reported for biochemical surrogate markers of CHD (blood lipids, measures of thrombosis or hemostasis), so this report cannot easily be integrated with results of studies where such data were reported (consistency).

Less persuasive than prospective studies in which CHD is measured, but still very useful, are prospective clinical trials in which surrogate markers for CHD are measured. These studies have usually used encapsulated fish oils providing omega-3 fatty acids in amounts comparable to or higher than the amount that would be consumed on a high fish diet (approximately one g EPA plus DHA per day), for periods of weeks to 6 months. These studies have not been designed to show an effect on the development of atherosclerosis, so evidence is lacking on that topic. Recent studies have not found beneficial effects on blood lipids from intake of omega-3 fatty acids in normal, healthy persons or in persons at risk for CHD, the same conclusion reached in the Federal government and other authoritative reports (Refs. 34 through 36, 63, and 115) regarding the effects of fish oils on serum lipids. This conclusion was also reached in numerous studies (consistency), some of which were large or multicenter (strength of association).

An increase in bleeding times and a decrease in platelet aggregation have been observed consistently in normal healthy individuals as well as in diseased persons who consumed fish oils. The effects of decreased platelet aggregation are plausibly related to the intake of omega-3 fatty acids, and there is a dose-response relationship. What has not been established, however, is that platelet aggregation is a bona fide surrogate risk factor for CHD in the general population.

Omega-3 fatty acids have been shown to reduce blood pressure in hypertensive people to a small degree, which may bear on a relationship between omega-3 fatty acids and CHD. The effect was not of large magnitude, but it is specific to omega-3 fatty acids, has been reported by a number of investigators, a dose response was found, and the effect is plausible. However, it has not been established that omega-3 fatty acids reduce blood pressure in normal subjects (lack of consistency, weak effect, absence of dose-response relationship). Additionally, it has not been demonstrated that the magnitude and duration of changes in platelet function or blood pressure observed in short-term studies will persist during long-term consumption of omega-3 fatty acids. Finally, the potential that omega-3 fatty acids may further increase the risk of CHD, through increases in LDL cholesterol or apoB among diabetics and hyperlipidemics, and the potential that omega-3 fatty acids may worsen control of blood glucose in diabetics, are significant safety concerns.

In conclusion, the totality of scientific evidence does not support the claim that omega-3 fatty acids reduce the risk of CHD.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(1) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

VI. Comments

Interested persons may, on or before January 27, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VII. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VIII. References

The following references have been placed on display in the Dockets Management Branch (address above) and may be seen by interested persons between 9 a.m. and 4 p.m., Monday through Friday.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR Part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371)

2. Section 101.71(f) is amended by adding new paragraph (f) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(f) Omega-3 fatty acids and coronary heart disease (insert cite and date of publication in the **Federal Register** of the final rule).

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

TABLE 1.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: SURVEYS, CROSS-SECTIONAL, AND CORRELATIONAL STUDIES

Reference	Design	Subjects	Duration	Base diet	Method	Comments	Findings
Bang et al. 1980 Advances in Nutrition Research 3:1.	Three expeditions: Dietary and blood lipids surveys. Comparison of CHD mortality rates and blood lipids between Greenlanders and Danes.	Cross-sectional studies including dietary survey. Blood lipids for 130 people, CHD rates based on hospital records.	3 short expeditions.	Greenlanders consumed 13.7 g omega-3 fatty acids/d and 5.4 g omega-6 fatty acids/d. Danes consumed 2.8 g omega-3 fatty acids/d and 10.0 omega-6 fatty acids/d.	Correlational	Other major risk factors for CHD including smoking, exercise, were not controlled. Sample size was small. Good hypothesis generating studies.	CHD rates and blood cholesterol were lower among Greenlanders in Greenland, who had high consumption of omega-3 fatty acid in marine foods, than among Greenlanders who migrated to Denmark, and who had lower omega-3 fatty acid consumption.
Crombie et al. 1987 European Heart Journal 8:560.	Cross-sectional	WHO mortality data and organization for economic cooperation and development statistics (Commodity).	Short-term	Per capita food consumption statistics.	Correlation between food consumption statistics and mortality rates from CHD in 15 nations.	Major CHD risk factors, spoilage, export of foods, genetic differences.	Some nations with high fish consumption had high rates of CHD mortality and some nations with low fish consumption had low CHD mortality rates.
Curb and Reed 1985 New England Journal of Medicine 313:821.	Prospective study	7,615 healthy Japanese men.	12 years	Reported fish consumption (24 hour recall).	Adjusted for major risk factors associated with CHD.	Letter to the editor	No significant trend for CHD and fish consumption.
Dolecek and Grandits 1991 World Reviews of Nutrition and Dietetics 66:205.	Prospective study with periodic dietary surveys.	6,258 men	9 years	24 hour recall of dietary intake.	Adjusted for major risk factors associated with CHD.	One of few studies to evaluate omega-3 fatty acid intake. Individuals with a history of CHD excluded from this study.	Mortality due to CHD inversely proportional to 20:5, 22:5 and 22:6 omega-3 fatty acids. Dose response effect reported.
Hirai et al. 1980 Lancet ii:1132.	Cross-sectional data used to correlate diet with CHD mortality rates in two villages with different fish consumption patterns.	42 healthy subjects from both fishing and farming communities in Chiba, Japan.	Short-term	Normal diet	Estimated fish, omega-3 fatty acid intake related to platelet aggregation, blood viscosity.	Hypothesis generating study; need cohort studies.	Inverse relationship between fish intake and rate of CHD mortality in the community.
Hunter et al. 1988 American Journal Preventive Medicine 4:5.	Nutritional survey data for fish consumption and CHD mortality data Canadian Atlantic provinces and Prairies.	Per capita average intakes of fish.	Short-term	Normal diet	Correlation of diet with CHD mortality rates.	Data do not relate to individuals, not adjusted for major risk factors for CHD. Need cohort data on food intake/CHD mortality.	Comparison did not indicate a measurable difference in CHD mortality rates despite greater fish consumption in Atlantic Provinces.
Iso et al. 1989 Internal Journal of Epidemiology 18:374.	Diet, clinical survey data correlated with CHD mortality rates. Cross-sectional design. Habitual fish intake questionnaire.	136 men total 34–55 years old: rural Japanese, urban Japanese, Japanese Americans, Caucasian Americans.	Short-term	Normal diet	8–12 hour fasting blood samples for blood lipids. Systolic and diastolic blood pressure.	Good survey techniques. Need cohort data on CHD mortality. This is primarily a hypothesis generating study.	Progressive decline in fish consumption from rural Japan to urban Japan, Japanese Americans and Caucasian Americans. There was an inverse correlation between CHD rates and fish consumption in these populations. Serum omega-3 fatty acids correlated most strongly with dark meat fish intake.
Kagawa et al. 1982 Journal Nutritional Sciences and Vitaminology 28:441.	Cross-sectional study	77 elderly persons on Kohame Island.	Short-term	Normal diet	Correlation	This is primarily a hypothesis generating study.	Higher serum levels of eicosapentaenoic acid and high density lipoprotein, lower salt intake and blood pressure in Islanders than mainland Japanese. Mortality due to hypertension and chronic heart disease lower than mainland Japan.

TABLE 1.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: SURVEYS, CROSS-SECTIONAL, AND CORRELATIONAL STUDIES—Continued

Reference	Design	Subjects	Duration	Base diet	Method	Comments	Findings
Kromhout et al. 1985 New England Journal of Medicine 312:1205.	Prospective study dietary questionnaire.	852 healthy men in Zutphen, Holland.	20 years	None	Adjusted or major CHD risk factors.	Inverse relationship between fish consumption and CHD mortality.	First study to report dose response. Noted lean fish, low in omega-3 fatty acids, had some protective effect against CHD.
Kromhout 1989 Journal Internal Medicine (suppl) 225:	Prospective study (number of subjects not given in paper). Review article presenting brief summary of previously unpublished information.	16 cohorts in 7 country study. Categorization of fish intake as group rather than as individuals.	15 years	Questionnaire at entry to survey level of fish consumption quintiles from <10 g/day to 200 g/day.	Correlation	Author suggested that CHD mortality not primarily dependent on level of fish consumption. Other behaviors including level of saturated fat in the diet are important. Need cohort data, unable to determine fish consumption in individuals with CHD mortality from this analysis.	Low mortality <20 deaths due to CHD per 1000 reported in all quintiles of fish intake. One cohort reported 60 g/day average intake and had ≤120 deaths per 1000 due to CHD. Controlling these factors, fish consumption at a low level may be of importance in the prevention of CHD.
Norell et al. 1985 British Medical Journal 293:426.	Prospective	10,966 Swedes born between 1886–1925.	14 year followup.	Mail questionnaire	Adjusted for age, smoking, weight, sex, marital status, geography. Excluded people with history of hypertension, heart disease.	The author suggested the study supported a protective effect of fish consumption for CHD mortality. The data for this conclusion were weak.	The trend for CHD mortality versus fish consumption was barely significant at the 90% confidence level. The Chi square trend was not significant.
Shekelle et al. 1985 New England Journal of Medicine 313:820.	Prospective dietary questionnaire.	1931 middle aged men	25 years	Normal diet	Adjusted for major risk factors associated with CHD.	Letter to the editor	Inverse trend for risk of death and fish consumption.
Simonsen et al. 1987 Acta Medica Scandinavica 222:237.	Correlation of diet and serum lipids with CHD mortality rates in these communities.	14 males each from farming and fishing community.	Short-term	Normal diet	Correlation	Smoking, sample size, medical records.	No differences in CHD rates in the two communities despite 2.5 fold greater fish consumption in the coastal group.
Vollset et al. 1985 New England Journal Medicine 313:820.	Prospective study	11,000 healthy, middle aged men.	14 years	Questionnaire on diet, fish consumption.	Adjusted for major risk factors associated with CHD.	Letter to the editor	No relationship between fish consumption and CHD except in men under 45 years old.

Abbreviations used: CHD, coronary heart disease; d, days.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Abbey et al. 1990 *Arteriosclerosis* 10:85.	Randomized, double-blind, 3 oils.	6 weeks	3.4 g EPA plus DHA (MaxEPA) v safflower, linseed oils.	11 normotensive mildly hypercholesterolemic males.	NS Chol, HDL, IDL; ↑ LDL; ↓ TGs, VLDL TG and chol, apoB, apoA-I, apoA-II; ↑ ratio of apoA-1/apoA-II.	Concurrent linoleic acid (omega-6) and linolenic acid (omega-3) control groups allow conclusions about omega-3 fatty acid specific effects. Dietary intake was controlled, compliance was monitored by plasma fatty acids. Comparisons v baseline values, following 3-week safflower oil run-in ↓ HDL on linseed oil only. See Kestin et al. 1990
Agren et al. 1990 *Thrombosis Research* 57:565.	Randomized, dose response.	12 weeks	0.25, 0.5, 0.6 and 1.1 g EPA + DHA from freshwater fish.	100 healthy male students.	↓ platelet aggregation to collagen, ADP in two highest fish consumption groups; ↓ TXB, in high amount, longest time group; NS bleeding.	Effects on 1.5 fish meals/weeks (0.5 g EPA plus DHA) with 12-week duration of exposure. Moderate amount of freshwater fish intake can modified platelet function. Concurrent 0.4 fish meal/week control group was present. Dropouts not explained; N=13, 14, or 15 in Table 2. Design doesn't allow conclusions about omega-3 fatty acid specific effects.
Azar et al. 1989 *Kidney International* 36 (suppl 27):S239.	Non-blinded, uncontrolled.	1 month	6 g MaxEPA/d	7 male and 6 female hemodialysis patients	NS Chol, apoA; ↓ TGs, apoB, and apoB/apoA ratio.	Hyperlipidemia of hemodialysis patients received 6 g/d of MaxEPA for 1 mo had beneficial effect. The investigator suggested that long-term multicenter studies are needed to confirm the efficacy and tolerance of FO. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Bach et al. 1989 *Annals of Nutrition Metabolism* 33:359.	Randomized double-blind placebo-controlled trial.	5 weeks	1.3 or 2.5 g EPA plus DHA from salmon oil/d v Miglyol 812.	30 healthy adults	NS Chol, LDL, HDL, TGs; ↓ BP, plasma viscosity, RBC rigidity, platelet aggregation.	The control oil (Miglyol 812) consists of TG of primarily octanoic acid and decanoic acid. No fatty acid composition of the control and the test diet was given. The compliance of the diet was not monitored.
Bagdade et al. 1990 *Diabetes* 39:426.	Non-blinded uncontrolled.	3 months	6 g EPA plus DHA, SuperEPA.	8 normolipidemic insulin-dependent diabetic women.	↓ TGs; ↑ Chol, HDL_2, apoA; NS LDL, apoB, HDL_3.	IDDM and NIDDM may respond to omega-3 fatty acids differently. No deterioration of diabetes control. Long-term benefits/toxicity not established. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Blonk et al. 1990 *American Journal Clinical Nutrition* 52:120.	Randomized, dose-response.	12 weeks	1.5, 3, 6 g EPA plus DHA ethyl esters/d.	45 normotriglyceridemic males.	↓ TGs, HDL_3; ↑ HDL_2, HDL_2: HDL_3; NS Chol, VLDL, LDL, total HDL; NS BP, bleeding time, RBC deformability, leukocyte killing.	Normal diets, with < 1 fish meal/week. Includes a 12-week washout, showing return to baseline for most variables. Compliance indicated by plasma phospholipids. Most of the observed changes occurred on the lowest dose.
Bonaa et al. 1990 *New England Journal Medicine* 322:795.	Randomized non-blinded, placebo controlled.	10 weeks	5.1 g EPA plus DHA as ethyl ester/d v corn oil.	157 hypertensive healthy, age 34 to 60.	NS Chol, HDL; ↓ BP linear with change in plasma EPA plus DHA; NS bleeding, fibrinogen.	FO decreased BP varies in different demographic and biochemical subgroups. In this study, 32% of the subjects did not decrease BP, despite an increased intake of EPA.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Borkman et al. 1989 *Diabetes* 38:1969.	Randomized, double-blind, placebo controlled.	3 weeks each.	10 g MaxEPA/d or 10 g safflower oil, with 3-week washout between.	10 non-insulin dependent diabetics.	NS Chol, LDL, HDL; ↓ TGs for hypertriglyceridemics only; NS c-peptide, fasting insulin, insulin sensitivity.	Controlled (diabetic) diet; ↑ fasting glucose comparable on both oils.
Bowles et al. 1991 *Angiology* ZZ:187.	Non-blinded uncontrolled.	6 months	2.8 g EPA in FO/d	120 vessels in 105 patients undergoing angioplasty.	NS v historic rates of restenosis.	Numerous shortcomings, including inclusion, exclusion criteria, unblinded uncontrolled, poor compliance.
Brown et al. 1990 *American Journal Clinical Nutrition* 52:825.	Randomized crossover.	6 weeks	5 g MaxEPA/d or lean fish (0.2 g EPA) plus 5 g MaxEPA.	12 healthy males	↓ TGs, VLDL; NS Chol, LDL, HDL_2, HDL_3.	Uncontrolled weekend evening meals, otherwise diet was controlled. Compliance was measured by the level of EPA in RBC The calorie intake of the control group (2968 Kcal) was 10% more that the FO (2633 Kcal) group.
Brown and Roberts 1991 *Arteriosclerosis and Thrombosis.*	Matched, single-blind, placebo controlled.	6 weeks	5 g FO v olive oil	11 healthy subjects on FO, 14 controls.	NS Chol; ↓ TGs on FO, HDL on olive oil.	Eructation revealed group to all FO subjects, but none of controls. ↓ post prandial lipemia in FO subjects. FO not characterized. Compliance by RBC fatty acids. Drop-outs accounted.
Burr et al. 1989 *The Lancet* ii:757.	Randomized, parallel, multicenter.	2 years	Fish advice (or MaxEPA at 0.9 g EPA plus DHA/d) v fat advice v fiber advice.	2033 men post heart attack.	↓ total deaths in fish advice v other groups, attributed to CHD death; NS second MI.	This is the only study to date which assessed effect of omega-3 fatty acids on CHD per se. Design doesn't allow conclusions about omega-3 fatty acid-specific effects, because effects of fish are not distinguished from effects of omega-3 fatty acids.
Childs et al. 1990 *American Journal of Clinical Nutrition* 52:632.	Non-blinded multiple crossover.	3 weeks	4 diets w 36% fat with EPA plus DHA as: 0.2%, butter; 6.7%, pollack; 9.4%, tuna; 6.2%, salmon blend.	8 normolipidemic males.	↓ TGs, VLDL, Chol, apoA-I and apoA-II on all fish diets, LDL on all but the pollack diet; HDL_2 ↓ on pollack, ↑ on salmon; HDL_3 on pollack, tuna.	Daily energy intake varied (2550–3618 kcal/d) among individuals. Saturated fat diet was used as positive control, no concurrent polyunsaturated fat control. The differential effects of pollack v other fish may be due to its higher ratio of EPA:DHA.
Clark et al. 1989 *Kidney International* 36:653.	Non-blinded uncontrolled.	5 weeks	6 g or 18 g MaxEPA/d.	12 subjects with systemic lupus erythematosus.	↓ TGs, VLDL; ↑ HDL, ↑ PGI_3; NS Chol PGI_2; ↓ platelet aggregation, blood viscosity, RBC flexibility; NS platelet serotonin, serotonin release.	All patients were receiving prednisone at doses ranging from 10 mg on alternate days to 20 mg daily. The results did not indicate an improvement in clinical outcome for patients with lupus nephritis.
Cobiac et al. 1991 *American Journal of Clinical Nutrition* 53:1210.	Matched, parallel design.	5 weeks	4.5 g EPA plus DHA from salmon plus sardines in sild oil v MaxEPA v palm, safflower olive oil mix.	25 mildly hypertensive men.	NS Chol, LDL, apoB, apoA-I, apoA-II, BP; ↓ TGs, VLDL; ↑ HDL on both fish and FO ↓ fibrinogen, TXB, ↑ bleeding on fish only.	3 week run-in on controlled diet including liquid supplement. Stratified by BP, TGs, Chol to matched groups; fish, FO or control (basal) diets. Fish diet EPA:DHA was 1:2, MaxEPA is 2:1. The BP effects were comparable in the 3 treatments. Bleeding, fibrinogen and thrromboxane changes occurred only on the fish diet, suggest they are EPA-specific effects.
Croset et al. 1990 *Thrombosis Research* 57:1.	Randomized, double-blind, placebo controlled trial.	2 months	100 mg EPA/d as purified TG plus tocopherol v vitamin E.	8 healthy elderly subjects, 8 controls.	NS Chol, TGs; ↓ platelet aggregation; NS arachidonic acid metabolites; ↑ tocopherol in platelets; NS fibrinolytic activity; ↓ systolic BP.	Decrease in platelet aggregation occurred on this very low dose (100 mg/d), despite no change in platelet or plasma EPA concentration Purified EPA containing TG as unique EPA source.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Dart et al. 1989 *Atherosclerosis* 80:119.	Double-blind, placebo controlled crossover.	2 months	20 mL MaxEPA v olive oil.	14 male and 7 female hypercholesterolemic subjects.	NS Chol; ↓ TGs, VLDL; for males ↑ LDL and HDL, for females NS LDL, HDL.	Sex differences in HDL response appears real Body weight gain on placebo in both men and women
DeCaterina et al. 1990 *Circulation* 82:428.	Non-blinded uncontrolled.	28 days	3 g EPA plus 1 g DHA/d (PGE technology, MA).	13 males 2 females with coronary artery disease.	↓ TGs; NS Chol; ↑ PGI_2; ↓ TXB_2; platelet aggregation ↑ bleeding.	No placebo-treated concurrent control group Assays of tissues from supplemented subjects indicate direct and indirect effects of omega-3 fatty acids on production of platelet function regulators
Deck and Radack 1989 *Archives of Internal Medicine* 149:1857.	Randomized double-blind placebo controlled crossover.	8 weeks	4.6 g EPA plus DHA/d source not specified v olive oil.	8 hypertriglyceridemics.	↓ TGs; ↑ apoB, HDL; NS LDL.	Small sample size may limit the ability to detect statistically significant changes in LDL cholesterol
Dehmer et al. 1988 *New England Journal of Medicine* 319:733.	Randomized non-blinded.	1 week prior to angioplasty for 6 months.	5.4 g EPA plus DHA/d (MaxEPA—).	82 male candidates for angioplasty.	↓ restenosis rates	Concurrent use aspirin (325 mg/p/d) and dipyridamole (225 mg/p/d) in the control and test groups
DeLany et al. 1990 *American Journal of Clinical Nutrition* 52:477–85.	Non-blinded, matched by serum cholesterol.	5 weeks	3 diets; basal; 5; or 20 g FO substituted for margarine (Sanomega).	15 healthy male college students.	20 g FO ↓ TGs; NS Chol, HDL, apoA–I, apoB on both FO diets.	The trial was conducted in healthy males consuming a constant controlled diet. Implementation of controlled diet alone decreased serum TG. A further reduction of serum TG was observed in 20 g FO
Demke et al. 1988 *Atherosclerosis* 70:73.	Randomized, double-blind placebo controlled.	28 days	5 g MaxEPA v safflower oil placebo.	31 hypercholesterolemic subjects.	↑ Chol, LDL, HDL, HDL_3; NS TG, bleeding, TXB_2; no changes in placebo.	The results of the experiment question the benefit of FO supplement to the hypercholesterolemic patient It is one of the few studies reporting ingestion of oil supplement has adverse effects; indigestion, diarrhea, headache abdominal cramps, etc Dietary intake was not controlled.
Emeis et al. 1989 *Blood* 74:233.	Stratified, randomized.	6 weeks	Fish paste (1.7 g EPA plus 3 g DHA) v meat paste.	37 normal healthy males in fish group, 39 in meat group.	NS TPA, fibrinogen, c-reactive protein, insulin, plasminogen activity; ↑ PAI–1 activity.	Design doesn't allow conclusions about omega-3 fatty acid-specific effects. 2-week run-in on the meat diet. Compliance monitored by urinary lithium. ↑ PAI is a risk factor for reinfarction
Endres et al. 1989 *New England Journal of Medicine* 320:265.	Non-blinded uncontrolled.	6 weeks	18 g MaxEPA	9 healthy adults	↓ interleukin 1, tumor necrosis factor.	Initial study group consisted of 6 subjects, three more persons entered the study six months later Since the results were similar the data was pooled. No concurrent control. No dietary control and the mean calorie varied from 2000 to 3000 kcal/d. The FO effect on the synthesis of IL–1b continued 10-week-after omega-3 fatty acids supplementation.
Ernst 1989 *Journal of Internal Medicine Supplament* 225:129.	Randomized, double blind, placebo controlled.	6 weeks, 2 weeks each of 0.6 g EPA, 1.2 g EPA and 1.8 g EPA sequentially.	Neither the FO or the placebo were characterized.	20 healthy men	Reduced blood viscosity at 4 and 6 weeks.	Initial data demonstrating comparability of the treatment and control groups not shown. Other dietary controls not used, and values for the placebo group were lower at 4 and 6 weeks, but NS.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Failor et al. 1988 *Metabolism* 37:1021.	Non-blinded crossover, parallel control group.	3 weeks each w 3-week washout.	Saturated fat v safflower v salmon (and salmon oil).	4 familial combined hyperlipidemics, 4 normal controls.	↓ TG, apoA-1 in normals Familiial combined hyperproteinemia ↓ TGs.	Good experimental design. Dietary intake 3was recorded and compliance was monitored by RBC omega-3 fatty acids measurement. Small n may be the reason some differences were not found.
Fasching et al. 1991 *Diabetes* 40:583.	Non-blinded randomized, crossover to no supplement.	2 weeks each with 3-week washout.	30 mL FO/d EPAX 5000, Fabrikker, Oslo,6.3 g EPA + DHA.	8 subjects with impaired glucose tolerance.	↓ TGs, Chol, LDL, apoB; NS HDL, apoA-I; NS insulin, blood glucose.	1 kg gain (NS) in 2 weeks! Suboptimal control; Doesn't separate effects of omega-3 fatty acids from other oil components/cals.
Fisher et al. 1990 *American Journal of Clinical Nutrition* 51:804.	Non-blinded uncontrolled.	6 weeks.....	6 g EPA plus DHA/d, (30 mL cod liver oil).	9 normal subjects.....	↓ monocyte free radical production.	Dietary intake was not controlled. Design doesn't allow conclusions about omega-3 fatty acid-specific effects. The potential mechanisms of foam cell formation and its relationship with omega-3 fatty acids were discussed.
Flaten et al. 1990 *American Journal of Clinical Nutrition* 52:300.	Non-blinded randomized.	6 weeks.....	14 g FO (7.7 g EPA plus DHA)/d (Fabrikkar, Norway) v olive oil.	64 healthy males	↓ TGs, NS Chol; ↓ HDL, HDL_2; NS glucose; NS BP; 12% ↓ fibrinogen; NS gamma glutamyl transferase, monocyte LDL receptor activity.	Olive oil was the concurrent oil control group. Compliance was checked by RBC total omega-3 fatty acids composition. Calorie and major nutrient intake were comparable for the control and test group.
Friday et al. 1989 *Diabetes Care* 12:276.	Non-blinded uncontrolled.	8 weeks.....	8 g EPA plus DHA methyl esters/d (RES-Q1000).	8 non-insulin-independent diabetics.	↓ Chol, TGs, VLDL; NS LDL, HDL insulin; ↑ glucose.	No fatty acid composition was given on the Marine-lipid concentrate (RES-Q 1000, a methyl ester of EPA and DHA). Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Friday et al. 1991 *Arteriosclerosis and Thrombosis* 11:47.	Randomized, non-blinded, placebo-controlled multiple treatment trial.	3 weeks each with 3-week washouts.	12 g EPA plus DHA/d (salmon oil) v safflower oil.	5 familial hypercholesterolemics, 5 normal controls.	Comparable results for FH and normals, ↓ TGs, Chol, LDL, HDL v butter diet.	Precisely matched diets, small numbers but large changes in lipids. The n-3 content is quite high.
Fumeron et al. 1991 *American Journal of Clinical Nutrition* 54:118.	Randomized, butter-controlled.	3 weeks each.	6 g MaxEPA/d	36 normal, young, healthy males.	↓ TGs, VLDL-TG; NS Chol, apoB, apoA-I, total HDL, but ↑ HDL_2, apoE, LDL; ↓ platelet aggregation, ↓ PAI; PAI correlated to LDL.	Among the few studies showing ↑ HDL in normals (v butter). The ↑ PAI activity and LDL may offset ↓ platelet aggregation and ↑ HDL_2 regarding net CHD risk.
Glauber et al. 1988 *Annuals of Internal Medicine* 108:663.	Non-blinded uncontrolled.	4 weeks.....	18 g MaxEPA/d	6 males insulin-dependent diabetics.	↑ fasting glucose; ↓ glucose tolerance, fasting insulin, insulin response.	Deterioration of NIDDM patients' diabetic state by FO supplement but no evidence of adverse effect by fish. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Grigg et al. 1989 *Journal of American College Cardiology* 13:665.	Randomized, double-blind placebo-controlled.	4 months.....	3.0 g EPA plus DHA/d from MaxEPA v 50% olive oil, 50% corn oil.	108 subjects undergoing angioplasties.	↓ TGs, NS chol; NS in restenosis rate.	Restenosis evaluated by angiography.
Haglund et al. 1990 *Journal of Internal Medicine* 227:347.	Non-blinded uncontrolled, partial crossover.	3 to 4 weeks or 6 months.	15 or 30 mL ESKIMO-3 (Cardinova, Sweden) soybean oil placebo.	33 subjects either healthy or with coronary artery disease.	↓ TGs, Chol; ↑ HDL; ↓ BP, fibrinogen in high dose group; NS bleeding.	Data for normal and CHD patients are pooled. Similarly, tables compare results for each treatment to pooled initial values for all subjects.
Hardarson et al. 1989 *Journal of Internal Medicine* 226:33.	Non-blinded crossover intervention.	6 weeks.....	20 mL cod liver oil/d.	18 males 33-70 yrs...	NS arrythmia	Subjects were an average of 8 days after onset of symptoms. Various drugs were taken by the patients. Dietary intake wes not controlled.
Harris et al. 1988a *Journal of Lipid Research* 29:1451.	Multiple, sequential, non-blinded intervention.	4 weeks and 3 weeks.	24 g or 28 g EPA plus DHA/d from salmon oil Max EPA respectively.	7 and 8 normal subjects.	↓ TGs, VLDL; ↓ LDL v saturated fat diet, but NS v vegetable oil diet; NS HDL.	No wash out period between each test periods. High amount of omega-3 fatty acids.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Harris et al. 1988b *Annals of Internal Medicine* 109:465	Single-blind, placebo controlled	6 weeks	12 mL SuperEPA/d v safflower oil.	11 hypertriglyceridemics, 7 with hypercholesterolemia.	↓ TGs; ↑ LDL, apoB; NS HDL.	Plasma lipoprotein changes should be monitored and long-term effects should be evaluated.
Harris et al. 1988c *American Journal of Clinical Nutrition* 48:992.	Non-blinded uncontrolled, crossover	6 weeks each.	18 g MaxEPA or same amount of EPA and DHA from SuperEPA.	8 male type IV hyperlipidemics.	↑ TGs; NS Chol, ↑ LDL, apoB.	Methyl ester of EPA and DHA causes the same effects as TG-EPA and TG-DHA. This is a test for more concentrate omega-3 fatty acids supplement.
Harris et al. 1990 *American Journal of Clinical Nutrition* 51:399.	Non-blinded uncontrolled, dose response	6 weeks	15, 25 or 40 mL MaxEPA/d.	10 hypertriglyceridemic subjects.	↓ TGs on each, little additional effect at high doses, ↓ VLDL; ↓ Chol but no effect of high doses; ↑ LDL, HDL on higher 2 doses.	High doses confound effects of increased calories. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Hostmark et al. 1988 *British Medical Journal* 297:180.	Randomized double-blind placebo-controlled supplement.	6 weeks plus 6 weeks.	14 g FO/d; 6.5 g EPA + DHA (Apothekernes Labs AS, Norway) v olive oil	64 males ages 35–40.	↓ fibrinogen 13% at 3, 6 weeks.	The reduction in fibrinogen was less at 6 weeks than at 3 weeks. Longer-term studies are needed for assessment of effects of chronic consumption of omega-3 fatty acids.
Hughes et al. 1990 *Atherosclerosis* 84:229.	Randomized, double-blind, placebo-controlled two way crossover.	30 days each, with 30-day washouts.	5 g EPA plus DHA/d (Promega), wheat germ oil control.	13 normal and 15 hypertensive males.	↑ Chol, LDL, apoB in hypertensives only; NS TG, BP, serum androgens, plasma glucose, insulin, platelet aggregation.	The hypertensives had ↑ apoB and ↓ HDL and ↓ androgens v normals at baseline. Reductions in TGs and VLDL were nearly 50% in normals and 40% in hypertensives, but did not reach statistical significance due to large variations.
Inagaki and Harris 1990 *Atherosclerosis* 82:237.	Non-randomized uncontrolled.	4 weeks	6 g EPA plus DHA/d (SuperEPA).	6 hypertriglyceridemics.	↓ TGs, VLDL, apoC; NS, LDL, apoA, apoE; ↑ HDL, apoB.	Useful regarding mechanism of changes in lipoprotein levels, separated TG from Chol and apoproteins.
Jensen et al. 1989 *New England Journal of Medicine* 321:1572.	Randomized, double-blind placebo-controlled crossover.	8 weeks	4.6 g EPA plus DHA/d from a water soluble cod liver oil preparation v olive oil.	14 males, 4 females insulin-dependent diabetics.	NS Chol, HDL; ↑ LDL; ↓ VLDL, TGs; ↓ BP;.	Concurrent olive oil control group was present Dietary intake was not controlled. Eight weeks washout period was long enough to restore the parameters tested to the pre supplementary level. No change in insulin or blood glucose.
Kasim et al. 1988 *Journal of Clinical Endocrinology Metabolism* 67:1	Non-blinded longitudinal.	8 weeks	1.6 g EPA plus 1.1 g DHA/d (MaxEPA).	22 insulin-independent diabetics w/o hyperlipidemia.	NS Chol, LDL, HDL; ↑ apoB; ↓ BP.	All patients received hypoglycemic agents. Compliance was monitored by questionnaires and counting the FO capsules. No plasma fatty acids composition was analyzed.
Kestin et al. 1990 *American Journal of Clinical Nutrition* 51:1028	Randomized, double-blind, 3 oils.	6 weeks	3.4 g EPA plus DHA (maxEPA), v safflower, linseed oils.	11 normotensive mildly hypercholesterolemic males.	NS Chol, HDL; ↑ LDL; ↓ TGs, VLDL.	Concurrent linoleic acid (omega-6) and linolenic acid (omega-3) control groups were present. Dietary intake was controlled, compliance was monitored by plasma fatty acids. Comparisons v baseline values, following 3 week safflower oil run-in ↓ HDL on linseed oil only. See Abbey et al. 1990.
Knapp and FitzGerald 1989 *New England Journal of Medicine* 320:1037.	Randomized, non-blinded.	4 weeks	10 or 50 mL MaxEPA v safflower oil of a mixed vegetable oil.	8 hypertensive males in each of 4 groups.	↓ BP on high dose only	No total calorie/d was given but one of the dose level used in the study was quite large (50 mL/d).

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Lehtonen et al. 1989 *Gerontology* 35:311.	Non-blinded, comparison to isocaloric diet.	3 weeks	70 to 80 mL MaxEPA/d.	17 healthy geriatric patients.	↓ Chol, VLDL, LDL, TG, apoA, HDL; NS apoB.	The fat content of the isocaloric control period is not given. This is a very large amount of FO. The majority of the patients discontinued the study due to unpleasant taste of the supplement oil.
Lempert et al. 1988 *American Journal of Kidney Diseases* 11:170.	Non-blinded, uncontrolled.	4 weeks and 20 weeks post-supplementation.	25 mL MaxEPA/d	11 stable dialysis patients, hypercholesterolemic, hypertriglyceridemic.	↓ TG, HDL; ↑ LDL; NS bleeding, platelet aggregation.	↓ HDL found 20 weeks after discontinuation, but little other data regarding treatment/condition during the washout. The nature of the disease and concurrent dialysis in this population make it impossible to extrapolate to the general population.
Levine et al. 1989 *Archives of Internal Medicine* 149:1113.	Non-blinded uncontrolled.	6 weeks	20 mL cod liver oil	10 hyperlipidemics	↑ Chol, LDL; NS HDL, TGs; ↑ platelet survival; NS platelet aggregation.	All the patients had long-standing history of hyperlipidemia. No concurrent oil control group. This study is one of the few studies that found plasma TG did not change after omega-3 fatty acids ingestion (20 mL/d).
Levinson et al. 1990 *American Journal of Hypertension* 3:754.	Randomized double-blind placebo-controlled parallel.	6 weeks	50 mL MaxEPA v palm oil, corn oil mix.	8 hypertensives	↓ TGs; NS Chol, HDL, LDL apoA and apoB; ↑ bleeding; NS platelet aggregation; ↓ Bp.	One patient receiving FO withdrew because of GI discomfort. Because of adverse effects, the daily dose of oil was reduced by 20% and 25% in two patients in the FO group, and by 20% in one patient in the vegetable oil group.
Li and Steiner 1990 *Blood* 76:938.	Non-blinded parallel	25 days	6 g EPA from MaxEPA.	8 normal adults	↓ platelet aggregation, adhesiveness.	Elegant study showing an effect on platelet adhesiveness. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Lox 1990a *General Pharmacology* 21:241.	Non-blinded uncontrolled.	30 days	0.9 g EPA plus DHA/d (MaxEPA).	9 healthy males	↓ Chol, LDL; NS TGs; ↑ HDL; ↑ bleeding; NS platelet aggregation.	Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Lox 1990b *General Pharmacology* 21:295.	Non-blinded uncontrolled.	30 days	0.9 g EPA plus DHA/d (MaxEPA).	43 healthy females, with or without oral contraceptive use, 13 menopausal females.	↓ Chol, ↑ LDL in non-oral contraceptive users; ↓ TGs in oral contraceptive users.	The difference between oral contraceptive users and non-oral contraceptive users may be important.
Margolin et al. 1991 *American Journal of Clinical Nutrition* 53:562.	Randomized, double-blind crossover.	8 weeks	9 g FO (RES-Q1000) v corn oil.	46 elderly hypertensive subjects.	↓ TGs; ↑ LDL; NS Chol, HDL; ↓ BP.	Inclusion BP was systolic >160 or diastolic >90. Excellent design with 3 week wash out between the 8 week treatments.
Mehta et al. 1988a *American Journal of Medicine* 84:45.	Randomized, double-blind placebo-controlled crossover.	4 weeks	3.2 g EPA 2.2 g DHA/d (MaxEPA) v lecithin.	8 males w CHD 52-73 yrs.	↓ TGs; NS Chol, HDL, LDL; ↓ BP, ↓ neutrophil aggregation, chemotaxis.	Placebo not characterized in this paper, identified from companion paper (see Mehta 1988, American Heart Journal). There was large variation of TG level in the placebo group.
Meht a et al. 1988b *American Heart Journal* 116:1201.	Randomized, double-blind placebo-controlled crossover.	4 weeks	3.2 g EPA 2.2 g DHA/d (MaxEPA) v lecithin.	8 males w CHD 52-73 yrs.	↓ PAI; NS TPA	Various parameters were compared between CAD patient and normal subjects. Lecithin was the concurrent control. Dietary intake was not controlled.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Miller et al. 1988 *Clinica Chimica Acta* 178:251.	Multicenter, randomized double-blind placebo-controlled.	3 months	10 g MaxEPA/d v olive oil.	48 hypertriglyceridemics.	↓ TGs; NS Chol, LDL, HDL	This is a multicenter 3 mo study. In the summary section the investigator reported minor GI disturbance in both groups but in the discussion section the author stated that 10 g MaxEPA/d was well tolerated. Compliance was not monitored.
Milner et al. 1989 *American Journal of Cardiology* 64:294.	Randomized	6 months	4.5 g EPA plus DHA/d (MaxEPA) v no supplement.	84 post-angioplasty patients.	↓ restenosis by symptoms, NS by angiography.	All patients received aspirin and calcium blockers American Heart Association phase III diet. Design doesn't allow conclusions about omega-3 fatty acid-specific effects. Concomitant use of other medications, reduction in smoking. Reocclusions not assessed by angiography.
Mölgaard et al. 1990 *Atherosclerosis* 81:1.	Non-blinded, placebo control.	16 weeks	15 g MaxEPA/d v olive oil.	9 type III hyperlipoproteinemics.	↓ Chol, TG, VLDL, apoB; NS LDL, HDL, apoA-I.	The European Atherosclerosis Society diet was recommended to the patients. No compliance was monitored. Concurrent olive oil control group.
Mori et al. 1988 *Clinical Experimental Pharmacology Physiology* 15:333.	Non-blinded uncontrolled.	3 weeks	15 g MaxEPA/d	10 insulin-dependent male diabetics.	↑ Chol, LDL, HDL; ↓ TGs	Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Mori et al. 1989 *Metabolism* 38:404.	Non-blinded, parallel control.	3 weeks	15 g MaxEPA/d v same in non-diabetics.	10 insulin-dependent male diabetics, 10 normal controls.	↑ Chol, LDL, HDL, HDL_2 ↓ TGs among diabetics; NS Chol, LDL, HDL, HDL_2 TGs among normals; Chol, LDL and TG still different 6 weeks after discontinuation.	Compliance by platelet phospholipids fatty acids and pill count. Usual diet, activity were to be maintained.
Nozaki et al. 1991 *American Journal of Clinical Nutrition* 53:638.	Non-blinded uncontrolled.	24 days	20 g Promega/d	12 male hypertriglyceridemics.	↓ TGs, VLDL; ↑ LDL; NS HDL.	No alcohol and isocaloric controlled diet was used in the protocol. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Radack et al. 1989 *Annals of Internal Medicine* 111:757.	Randomized double-blind placebo-controlled supplement.	20 weeks	1.1 or 2.2 g EPA plus DHA/d (source not specified) v olive oil.	25 hyperlipidemic, disease free.	↓ fibrinogen	Excellent design. Compliance was assessed by plasma fatty acid analysis.
Radack et al. 1990a *Journal of American College Nutrition.*	Randomized, double-blind crossover.	8 weeks each 4-week washout, 6-week run-in.	4.6 g EPA plus DHA, olive oil during washout, corn oil control.	8 hyperlipoproteinemics types IIb or IV.	↓ fibrinogen comparably on FO and corn oil; NS TPA, PAI, bleeding.	Excellent design; although the n was small, the mean values do not suggest differences missed due to small sample, nor is any difference between corn oil and FO suggested.
Radack et al. 1990b *American Journal of Clinical Nutrition* 51:599.	Randomized, double-blind placebo-controlled.	20 weeks	2.2 or 1.1 g FO/d from McNeil, 41% as n-3 fatty acids v olive oil.	10, 7 and 8 hypertriglyceridemics, respectively.	↑ LDL, ↓ HDL_2 on 2.2 g/d group, ↑ apoB on both doses of FO.	Excellent design includes 6 week run in, AMA diet, 92% compliance, appropriate subjects for claims.
Reis et al. 1989 *The Lancet* ii:177.	Randomized, double-blind placebo-controlled.	6 months	6 g EPA plus DHA/d (SuperEPA or Promega).	204 patients for coronary angicplasty.	NS effect on restenosis	In a randomly selected subset of 42 patients (42/186), plasma PL was analyzed. Higher GI side-effect was significantly higher in FO group (48%) than placebo group. Placebo not characterized.
Reis et al. 1990 *American Journal of Cardiology* 66:1171.	Randomized, double-blind placebo-controlled.	6 months	6 g EPA plus DHA/d (SuperEPA or Promega) v olive oil.	89 patients for coronary angioplasty.	↓ TGs; ↑ LDL in Promega group and hypertriglyceridemic subjects of Super-EPA group.	Only subset of patients had LDL separated by ultracentrifugation. Most of LDL chol levels were calculated rather than measured.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Rillaerts et al. 1989 *Diabetes* 38:1412.	Non-blinded, uncontrolled.	10 weeks.....	2.7 g EPA plus DHA/d (MaxEPA).	12 stable insulin-dependent diabetics.	↓ TGs, VLDL; ↑ HDL; NS LDL during washout ↑ TGs, VLDL.	Dietary intake was controlled, exchanging sunflower, corn or safflower oil with omega-3 fatty acids. Calorie intake varied from 1800 to 2200 kcal, depend on individual needs. Approximately 5.6 g omega-6 fatty acids/d was exchanged with 2.7 g omega-3 fatty acids/d.
Schectman et al. 1988 *Diabetes* 37:1567.	Single-blind crossover.	1 month.....	4.0 or 7.5 g EPA plus DHA (MaxEPA).	13 non-insulin dependent diabetics v safflower oil.	↓ TGs, VLDL, NS Chol, LDL, HDL; ↑ apoB; ↑ fasting glucose, ↓ glucose tolerance.	Subjects were on their usual diet (uncontrolled). Compliance was obtained by capsule counting. Increase LDL chol and apoB were not dependent on amount of omega-3 fatty acids.
Schectman et al. 1989a *Arteriosclerosis* 9:345.	Single-blind crossover.	1 month.....	4.0 g/d EPA plus DHA (MaxEPA) for 1 month, 1-month washout, followed by 7.5 g/d for 1 month v safflower oil.	18 hypertriglyceridemic subjects.	↓ TGs; NS Chol, HDL, apoA–I on both treatments; NS on control.	Significant body weight gain on each treatment. Saturated fat was held constant.
Schectman et al. 1989b *Annals of Internal Medicine* 110:346.	Non-blinded uncontrolled.	6 months.....	10 g EPA plus DHA/d months 1 to 3; 4 g/d months 4 to 6 (Omega-500).	16 hypertriglyceridemics (5 also hypercholesterolemic); 6 noninsulin-dependent diabetics.	Initially ↓ TGs, but less each month, by 6 months only ↓ 11%; worse glucose tolerance, ↑ glycosolated hemoglobin in diabetics; ↑ HDL on high dose.	Dietary intake was not controlled. GI side effects were considered and reported. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Schmidt et al. 1988a *Artery* 15:316.	Non-blinded randomized after placebo.	12 weeks.....	4.5 g EPA plus DHA/d v vegetable oil.	14 patients with angina.	NS plasminogen, PAI; ↑ fibrinolysis.	Concurrent vegetable oil control was used. No fatty acid composition of control and test oil was given. Uncontrolled use of omega-3 fatty acids supplementation in patients with stable angina pectoris was cautioned by the investigator.
Schmidt et al. 1988b *Scandinavian Journal of Clinical and Laboratory Investigations*, Suppl.	Randomized, double-blind, placebo controlled.	12 weeks.....	4.8 g EPA plus DHA/d (MaxEPA) v vegetable oil.	36 patients with angina.	NS antithrombin III, protein C.	4-week run-in on vegetable oil control.
Schmidt et al. 1989a *Thrombosis and Haemostasis* 62:797.	Non-blinded uncontrolled.	6 weeks.....	6 g n-3 (3.3 EPA, 1.8 DHA) (Jahre, Norway).	17 hyperlipidemics (9 type IIa, 8 type IV.	↓ TGs; NS Chol, LDL, HDL; ↑ apoB, ↓ apoA–I; ↑ protein C in type IIa, ↓ type IV;.	No concurrent oil control group, uncontrolled dietary intake and large amount of test oil. Dietary compliance was not monitored and GI side effect was not reported. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Schmidt et al. 1989b *Journal of Internal Medicine* 225 (Suppl 1):201.	Non-blinded uncontrolled.	6 weeks.....	4 g EPA plus DHA/d (Jahre, Norway).	10 insulin-dependent diabetics.	NS fibrinogen, TPA, PAI, platelet aggregation; ↑ neutrophil, NS monocyte chemotaxis.	Very few changes in this population; the chemotaxis results are different than for normals. The meaning of changed neutrophil chemotaxis is unclear. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Schmidt et al. 1989c *Atherosclerosis*.	Non-blinded uncontrolled.	6 weeks.....	5.3 g cod liver oil/d....	12 normal, healthy males.	↓ neutrophil, monoctye migration toward autologous serum or chemical attractant.	Usual diets throughout. The lack of a control oil prevents firm conclusion about the specificity of the effect as due to omega-3 fatty acids.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Schmidt et al. 1991 *Arteriosclerosis and Thrombosis* 11:429.	Randomized, non-blinded dose-response.	6 weeks	6 g or 1.3, 4 or 9 g n-3 fatty acids (Fabrikker, Oslo).	17 hyperlipidemics and 10 healthy men.	↓ monocyte chemotaxis in all, ↓ neutrophil in type IIa and in normals, not type IV on 1.3 g/d.	Virtually all the effect is with the lowest dose. The authors interpret this to mean the effect was probably not due to polyunsaturated fatty acids, but a polyunsaturated fatty acid control would have allowed a stronger conclusion.
Skeaff and Holub 1988 *Thrombosis Research* 51:105.	Non-blinded v washout.	6 weeks	20 mL MaxEPA/d	8 normal males	↓ platelet aggregation	A methodology and protocol for biochemical mechanism of action of omega-3 fatty acids on platelet function. Design doesn't allow conclusions about omega-3 fatty acid-specific effects.
Silverman et al. 1991 *American Journal of Clinical Nutrition* 53:1165.	Non-blinded, crossover.	2 individual meals.	6.16 and 5.15 g EPA plus DHA from FO (Promega) or tuna, respectively.	10 normal, healthy males.	↓ platelet aggregation to one of four agonists; NS bleeding, membrane omega-3 fatty acids.	The study was undertaken primarily to measure absorption of omega-3 fatty acids from FO v fish EPA absorption from fish was about 3 fold greater than from FO, but there was no difference in DHA absorption rate.
Simons et al. 1990 *Australia New Zealand Journal of Medicine* 20:689.	Randomized double-blind placebo-controlled crossover.	12 weeks	2 or 4 g EPA plus DHA/d HIMEGA (ethyl esters) v olive oil.	13 hypertriglyceridemics and 9 hypercholesterolemics.	↓ TGs; HDL, and ($p < 0.06$) Chol; NS LDL, apoA-1, apoB.	Himega is ethyl ester preparation of FO fatty acids The study shows comparable results for the new and traditional FO.
Simonsen et al. 1988 *Acta Medica Scandinavica* 223:491.	Non-blinded, uncontrolled.	3 weeks	20 mL cod liver oil, about 5 g EPA plus DHA.	2 groups of 15 normal healthy males.	NS Chol, bleeding, TXA_2 ↑ HDL in the population with low fish consumption.	There was an alternate oil control.
Smith et al. 1989 *Thrombosis Research* 53:467.	Non-blinded, uncontrolled.	4 weeks	3.4 g EPA plus DHA as ethyl esters (K85, Norsk Hydro).	35 male and 5 female survivors of myocardial infarction.	↓ TGs; NS HDL, blood glucose, PAI; ↑ Chol, LDL, bleeding, fibrinogen.	Points out interaction of omega-3 fatty acids with anticoagulants.
Solomon et al. 1990 *Current Medical Research Opinion* 12:1.	Randomized double-blind placebo-controlled parallel longitudinal.	3 months	2.8 g EPA, 2 g DHA (MaxEPA) v olive oil.	10 stable angina patients.	NS angina	Concurrent olive oil control was used. The subject number (5/group) was too small. Subjects kept their usual diet and life-style. Compliance was assessed by RBC–PL fatty acid analysis. No side effects were reported.
Stacpoole et al. 1989 *Metabolism* 38:946.	Non-blinded uncontrolled, two doses.	6 months, 3 months on 2 diets.	1.1, 2.3, or 4.5 g EPA plus DHA/ 1000 Kcal (MaxEPA).	21 hyperlipoproteinemics 6 diabetics, 6 normals.	In diabetics ↓ TGs; ↑ LDL; NS Chol, HDL; TG and LDL changes show dose-response; Glycemic control worse in 4 insulin-dependent diabetics; In controls ↓ TG, VLDL; NS Chol.	Two kinds (MaxEPA or SuperEPA) of omega-3 fatty acids test materials were used. Compliance was monitored by monthly visiting the clinic and evaluated by a physician and dietitian rather than plasma fatty acids composition American Heart Association phase III diet was used as basal diet.
Steiner et al. 1989 *Journal of Hypertension* 7 (suppl 3):S73.	Randomized, placebo-controlled crossover, followed by non-blinded, uncontrolled phase.	8 weeks blind, 4 weeks open.	1.6 g EPA plus DHA blind v salad oil, 3.2 g EPA plus DHA non-blind.	28 hypertensives, including 10 with hypertriglyceridemia or hypercholesterolemia.	↓ BP for self-recorded and casual clinic-recorded; NS prostacyclin, thromboxane.	Considerable systematic difference between self-reported and clinic-reported BP data suggests significant patient bias, detectable by fish-smell belching. Quantitative data not presented, making comparison with other BP studies difficult.
Subbaiah et al. 1989 *Atherosclerosis* 79:157.	Non-blinded uncontrolled.	30 days	7.5 g EPA plus DHA/d as SuperEPA.	14 hypercholesterolemics w/o hypertriglyceridemics.	↓ TGs, VLDL, LDL; ↑ HDL	Patients on American Heart Association phase I diet for at least 3 mo before entering the study and continue the same diet during the test period.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Sweny et al. 1989 *Nephrology Dialysis Transplantation* 4:1070.	Non-blinded uncontrolled.	6 months	60 mg EPA plus DHA/kg (MaxEPA).	14 adult transplant recipients.	↓ TGs, NS Chol	No concurrent oil control group, uncontrolled dietary intake except dietary protein intake was kept constant. Compliance was not monitored and GI side effect was not reported. Antihypertensive and immunosuppressive drugs were administered.
Takimoto et al. 1989 *Thrombosis Research* 54:573.	Non-blinded uncontrolled, partial crossover.	30 days	20 mL MaxVita 5.6 g EPA 2.6 g DHA.	14 normal healthy subjects, 4 were hypercholesterolemic and hyperlipidemic.	↓ Tgs, HDL; NS Chol	There was no side effect or GI disturbance was reported when 20 mL control or test oil was taken in a single dose. Wheat germ oil containing alpha linolenic acid was used as control oil.
Urakaze et al. 1989 *Nephron* 53:102.	Non-blinded uncontrolled, controlled for ciclosporin.	6 months	1.5 g EPA 0.7 g DHA/d (source not specified).	14 renal allograft patients.	↑ RBC filterability, prevented ↑ in platelet aggregation in controls.	Non specified sardine oil concentrate was used. Food intake was not monitored during the study but EPA content in RBC was measured for compliance. Antihypertensive and immunosuppressive drugs were administered.
Vacek et al. 1989 *Biomedicine and Pharmacotherapeutics* 43:375.	Double-blind placebo-controlled crossover.	6 weeks	9 g EPA plus DHA from (MaxEPA) v 1:1 palm: cottonseed oil.	8 CHD patients	↓ TGs; NS Chol, LDL, HDL; NS angine.	The control was a mixture of palm and cottonseek oils. No fatty acid composition was given of this control oil. Dietary intake was not controlled.
Valdini et al. 1990 *Journal of Family Practice* 30:55.	Randomized, double-blind, placebo-controlled crossover.	12 weeks each.	1.8 g EPA plus DHA/d (MaxEPA) v olive oil.	25 hypercholesterolemics.	↓ TGs; NS Chol, LDL, HDL	Usual diets, small but practical dose; some patients were on lipid altering medication concurrently.
van Houwelingen et al. 1990 *American Journal of Clinical Nutrition* 51:393.	Multicenter, matched controls by TGs and blood pressure.	6 weeks	mackerel (4.7 g EPA + DHA) or meat paste.	84 healthy males	NS Chol, LDL; ↓ TGs at 3 and 6 weeks; at 6 weeks ↑ apoB v meat paste; NS v initial on meat paste.	Excellent design, includes 2 week run in; doesn't distinguish fish from n-3 fatty acids, large amt of n-3s.
Vessby and Boberg 1990 *Journal of Internal Medicine* 228:165.	Randomized double-blind placebo controlled crossover.	8 weeks	10 g MaxEPA v olive oil.	14 non-insulin dependent diabetics.	both oils ↓ VLDL, Chol, apoA-II; MaxEPA also ↓ TGs, BP, but NS between treatments; HbA_{1c}, glucose disappearance ↑ on MaxEPA, ↓ on olive oil.	Indicates potential adverse effect on glucose by omega-3 fatty acids.
Wahlqvist et al. 1989 *The Lancet* ii:944.	Non-blinded uncontrolled.	7 day diet records.	100 g fish/week	31 healthy 22 non-insulin-dependent diabetics.	↑ arterial compliance in fish group; ↓ posterior tibial artery resistance in healthy subjects.	Very small amount of fish (rather than FO supplement) was used in this study. Fish eaters were defined as those who ate one serving (100 g) or more of fish in a week. No total and/or a range of omega-3 fatty acids was given in the study.
Weintraub et al. 1988 *Journal of Clinical Investigation* 82:1884.	Non-blinded uncontrolled.	25 days	3 diets; saturated fat; safflower oil; FO at 30% of fat.	8 healthy normolipidemic males.	↓ TGs, Chol more by FO than safflower; ↓ VLDL, LDL, HDL comparable v saturated fat diet except apoA ↓ on FO v saturated fat.	The fat content (42%) of the diet was too high but the study design using two controls, saturated fat and omega-6 fatty acids was good.
Wilt et al. 1989 *Annals of Internal Medicine* 111:900.	Randomized, double-blind placebo-controlled crossover.	12 weeks each with 4-week washout.	20 g MaxEPA v safflower oil.	38 males w hypercholesterolemia.	↓ TGs; ↑ LDL; NS Chol, HDL, apoA, apoB.	Patients were on American Heart Association step one low cholesterol, low sat fat diet and large amount of FO (20 g/p/d) was used. No GI side effect was reported. Compliance was monitored by blinded pill count and questionnaire rather than plasma lipid analysis.

TABLE 2.—OMEGA-3 FATTY ACIDS AND CORONARY HEART DISEASE: CLINICAL STUDIES—Continued

Reference	Design	Duration	Amount	Subjects	Findings	Comments
Zucker et al. 1988 *Artherosclerosis* 73:13.	Randomized, crossover.	6 weeks.....	3.2 g EPA 2.2 g DHA (MaxEPA) v safflower oil.	9 normal, 16 hyperlipoproteinemics.	↓ TGs, VLDL; ↑ LDL in type IV hyperlipoproteinemics; NS Chol, TG, LDL, HDL among normals.	Safflower oil was used as control oil. The study design was double blind but many of the subjects reported identifying the FO by its characteristic aftertaste. This is one of the very few article reported FO aftertaste in a double blind study.

Abbreviations used: NS, not statistically significantly different; Chol, cholesterol; VLDL, very low-density lipoprtein cholesterol; LDL, low-density lipoprotein cholesterol; HDL, high-density lipoprotein cholesterol, TGs, triglycerides; apoA, apoprotein A (a protein in high-density lipoprtoein); apoB; apoprotein B (a protein in low-density lipoprotein); apoE, apoprotein E (a protein in many lipoproteins, most notably VLDL and HDL; CHD, coronary heart disease; FO, fish oil; TXB, thromboxane; TPA, tissue plasminogen activator; PAI, plasminogen activator inhibitor; v, versus; /d per day.

[Docket No. 91N-0094]

RIN 0905-AB67

Food Labeling: Health Claims; Calcium and Osteoporosis

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to authorize the use on food labels and in labeling of health claims relating to the association between calcium and osteoporosis. FDA has reviewed the available scientific data under the provisions of the Nutrition Labeling and Education Act of 1990. Based on its review, FDA has tentatively concluded that there is significant scientific agreement among qualified experts that this data supports that calcium intake has a significant impact on bone health. The agency proposes that for a product to be eligible to bear such a claim, one serving of the product must contain a minimum of 20 percent of the Recommended Daily Intake (RDI) for calcium or 180 milligrams (mg) in an assimilable form.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Mona S. Calvo, Center for Food Safety and Applied Nutrition (HFF-265), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-485-9564.

SUPPLEMENTARY INFORMATION:

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the Nutrition Labeling and Education Act of 1990 (Pub L. 101-535) (the 1990 amendments), which amend the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary) to issue regulations authorizing nutrient content or health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under section 403(r)(1)(B) of the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this issue of the **Federal Register** is a proposed rule to establish general requirements for health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs or other nutritional substances (referred to generally as "substances") to a disease or health-related condition on food labels and in labeling. In this companion document, FDA has tentatively determined that such claims would be justified only for substances in dietary supplements as well as in conventional foods if the agency determines based on the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) that there is significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (section 3(b)(1)(a)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)) that, within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act (21 U.S.C. 343(r)), and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including calcium and osteoporosis, meet the requirements of the act. In this document, the agency will consider whether a label or labeling claim on food or food products, including conventional foods and dietary supplements, on the relationship between calcium and osteoporosis would be justified under the standard proposed in the companion document entitled "Food Labeling: General Requirements for Health Claims for Food."

FDA has followed the general concepts and criteria proposed in the companion document in considering whether to propose to authorize the use on the labels and labeling of food of health claims for calcium and osteoporosis. In the companion document, FDA has proposed that, in evaluating whether support exists for a health claim, it will consider the levels and safety of a nutrient within the context of its use in the daily diet. Before a health claim for a particular nutrient will be authorized, it is necessary that the nutrient be safe and lawful for use in food at the level found to have an effect on a disease or health condition.

The topic of calcium and osteoporosis involves a substance which has recognized uses both as a component of food and of drugs. The agency has looked at all data relevant to this topic whether the data involved tests at dietary levels or at therapeutic levels. The agency thought this necessary to

ensure the completeness of its review. However, the agency emphasizes that this proposal is only about whether a claim has been justified for calcium and food. A component of food must be safe in the context of the daily diet. On the other hand, drugs may be used even if they present questions of safety to the general population, and even to the population being treated, on the basis that there is a benefit from its use that outweighs the potential risk.

B. Definition and Disease Prevalence, Morbidity, Mortality, and Health Costs

Osteoporosis is a disease characterized by low bone mass, where the internal structure of the bone has been eroded to the extent that even slight trauma will cause the bone to fracture easily (Ref. 7). An estimated 75 million people are afflicted with osteoporosis in the United States, Europe, and Japan (Ref. 7). These estimates include one in three women over 65 years and more than half the elderly men and women over 75 years.

Osteoporosis causes more than 1.3 million fractures per year in the United States, typically involving the spine, wrist, hip and ribs (Ref. 109). Because life expectancy in the United States will soon average in the eighties, osteoporosis is expected to affect an even larger proportion of our population (Ref. 20). By age 80, approximately 40 percent of all women will have sustained a wedge-type fracture of the spine, a common source of pain, disability, and deformity, resulting in progressive loss of height with age (Ref. 109).

Fractures of the hip, however, have the greatest health and economic impact. In 1985, approximately 250,000 hip fractures occurred in the United States, primarily in persons over age 45 (Refs. 20 and 101). An estimated 12 to 20 percent of the hip fracture victims die within the year following the fracture (Ref. 83). Among those that do survive, a significant proportion never regain their prefracture independence and require varying degrees of nursing and often permanent custodial care (Ref. 7).

Estimates of the annual financial costs of osteoporosis in the United States, based primarily on the cost of hospitalization and acute and long-term care services were $6.1 billion dollars in 1984 (Ref. 5) and are currently thought to exceed $10 billion dollars (Ref. 8).

C. Risk Factors and Populations at Risk

The most important risk factors for osteoporosis and associated bone fractures are age, gender, race (Caucasian or Asian), and hormonal status (Refs. 1, 2, 3, 5, 7, 10, 83, and 109). For women, hormonal changes associated with menopause (natural or premature cessation of the menstrual cycle) places them at increased risk (Ref. 118). In addition, evidence exists identifying low dietary calcium, cigarette smoking, and alcohol intake as factors in the development of osteoporosis (Refs. 2, 8, and 109). In general, factors that impair maximum bone formation early in life and those that underlie excess postmenopausal and age-associated bone loss later in life will predispose persons to osteoporosis.

D. Calcium's Nutrient and Physiologic Function

The human body contains approximately 1,000 grams (g) of calcium, 99 percent of which is found in the skeleton and a small but very important 1 percent is found in the plasma and soft tissues (Ref. 21). Calcium is an essential nutrient. In terms of its physiological function, calcium is probably one of the most critical minerals in the body. Within bone, calcium provides structure and support. The bone's exchangeable calcium pool allows for calcium storage that can be readily released in times of need. When this pool is exhausted, bone can be resorbed, that is, physically broken down to release needed calcium (Ref. 100). Within plasma and cells, calcium functions in bone mineralization, blood clotting, membrane stability and permeability, nerve conduction, muscle contraction, cellular secretion, regulation of ion transport, enzymatic activity, and cell growth and differentiation (Refs. 21 and 100). Plasma calcium levels are maintained within a very narrow range through the interaction of three hormones whose actions raise or lower the calcium levels appropriately in order to maintain proper physiologic function (Ref. 100).

While bone can serve as a temporary source of calcium during acute physiologic need, the body is dependent on dietary intake as the ultimate source of calcium to replete the skeletal reserves (Ref. 67). When increased demand for calcium results in excessive resorption of calcium from bone, the structural support function of bone is compromised, and the bone breaks easily (Refs. 21 and 30).

Because of its essential function in the maintenance of plasma calcium within such narrow limits, bone is constantly turning over and remodeling and thus remains a dynamic tissue throughout life. The process of bone remodeling consists of the tightly coupled actions of bone resorption and bone formation. It is thought that through changes in bone remodeling activity, factors such as dietary calcium, exercise and hormonal activity modulate the rate of bone loss or gain (Refs. 34 and 64).

The need for calcium throughout life varies with bone remodeling activity and is reflected in the dietary guidelines for calcium intake, which suggest highest intake during adolescence and early adult life when the greatest net growth of bone occurs (Ref. 3). Many experts argue that because of the increase in the bone resorption component of the remodeling activity that occurs at menopause in women, there is also a need for greater calcium intake at this stage of life (Refs. 23 and 67).

E. Importance of Peak Bone Mass and Its Relation to Calcium

Peak bone mass, the total quantity of bone present at skeletal maturity, may have the greatest bearing on whether or not a person is at risk of developing osteoporosis later in life. Most bone experts support the idea that the best way to reduce the risk of osteoporosis is to maximize the amount of bone formed at skeletal maturity which occurs by approximately age 35 (Refs. 2, 10, 16, 64, and 91). Experts agree that two factors, adequate calcium intake and physical activity, are critical to maximizing the amount of bone formed at skeletal maturity (Refs. 67, 91, 109, and 118). It is also widely held that if calcium intake is not adequate during childhood, adolescence, and early adulthood, full skeletal potential may not be attained (Refs. 16, 37 and 64).

Throughout life, bone is constantly changing and remodeling, but the components of bone remodeling, that is the rates of bone resorption and formation, differ at different stages of the life cycle. At puberty, bone formation occurs at an accelerated rate which results in an increase in both the length and density (mass) of bone (Ref. 118). While little to no further growth in length is experienced after the pubescent growth spurt, bone continues to grow in width and in mass adding approximately 10 percent or more mass over the next 10 to 15 years (Refs. 63 and 118). This later phase is known as the period of consolidation and continues until about 35 years of age, at which time a person is considered to be at peak bone mass or skeletal maturity (Refs. 10 and 118).

At midlife, between the ages of about 35 to 45, bone continues to remodel, but bone mass is maintained without change (balanced rate of resorption and formation). Thereafter, bone is lost at a constant rate of 0.3 to 0.5 percent per

year in both men and women (greater rate of bone resorption) (Ref. 20). Prior to and after menopause, women lose bone at a faster rate (2 to 5 percent per year) than men, but eventually return (between about 60 and 70 years of age) to the same rate of bone loss as men (Ref. 20). During the menopause, a decrease in the female hormone estrogen is the factor underlying this rapid rate of bone loss (Refs. 20, 90, and 118).

The postulated mechanism underlying the relationship of adequate calcium intake and optimal peak bone mass to the reduced risk of osteoporosis relates to the assumption that since all persons lose bone with age, those with higher bone mass at maturity take longer to reach the critically reduced mass at which fractures occur with minimal trauma (Ref. 20). Genetic factors probably have the greatest influence on setting the upper limit of an individual's peak bone mass (Ref. 64). One explanation why men have a lower incidence of osteoporosis than women is that men are genetically programmed to have a higher peak bone mass (Ref. 74).

Racial differences observed in the incidence of osteoporosis are also thought to be related to differences in genetically determined upper limits of bone mass. For example, Caucasian women, particularly those of northern European ancestry, experience the highest incidence of osteoporosis related bone fracture, while American women of African heritage have greater bone density and significantly lower (approximately 50 percent) fracture rates (Refs. 28, 4, 118, and 136). Experts suggest that the greater initial bone density (peak bone mass) observed in African Americans explains why they have fewer osteoporotic fractures than Caucasians and Asians (Ref. 28, 41, 89, and 118). Nevertheless, weight bearing exercise and diet can also influence the maximal amount of bone achieved, and unlike genetic factors, diet and exercise can be easily manipulated (Refs. 10, 78, 102, and 109).

F. Role of Calcium After Peak Bone Mass

Bone density later in life depends on both the amount of bone made during growth (peak bone mass) and the subsequent rate of bone loss after maturity. The impact of dietary calcium on bone loss that occurs between ages 35 to 45 or after peak bone mass is achieved but before menopause, is unclear, because limited data are available characterizing the rate of bone loss that occurs. Maintenance of an adequate calcium intake during the onset of menopause at about 45 to 50 years of age is important and may help to slow the rapid loss of bone at this time (Refs. 47 and 102). However, because the rapid rate of bone loss that occurs early in menopause is largely the result of the hormonal changes associated with the onset of menopause, a high dietary calcium intake alone will not effectively slow the rate of loss during this period of early hormone withdrawal in women (Refs. 7, 52, 109, and 120). Failure of men to experience this period of accelerated bone loss resulting from hormonal withdrawal is another explanation for the sex difference observed in the incidence of osteoporosis (Refs. 20 and 118).

G. Summary of Mechanism of Action of Calcium

Current scientific thought suggests that there are two mechanisms through which calcium intake may influence bone remodeling and ultimately, the risk of osteoporosis and related bone fracture. The first mechanism involves maximizing the amount of bone that is formed at skeletal maturity and the second involves slowing the rate of bone loss with age. Both mechanisms would allow an individual to maintain a higher bone mass later in life, thereby reaching the critical fracture threshold much later in life.

H. Regulatory History

1. Calcium

Calcium-containing food ingredients are used in food for a number of functional effects. In preparing this proposal, the agency identified those ingredients currently in use and their functions, conditions of use, and limits on the level for which they can be added to food (Ref. 33). For the uses of these ingredients in food to be lawful, they must be either generally recognized as safe (GRAS), or affirmed as GRAS by FDA, listed in the food additive regulations, or subject to a prior sanction. Of the 36 or more calcium-containing ingredients identified by the agency as currently in use, only the following 10 compounds have been demonstrated to FDA's satisfaction to be safe and lawful for use in a dietary supplement, or as a nutrient supplement by FDA: calcium carbonate, calcium citrate, calcium glycerophosphate, calcium oxide, calcium pantothenate, calcium phosphate, calcium pyrophosphate, calcium chloride, calcium lactate, and calcium sulfate.

FDA also allows the addition of calcium-containing compounds to certain foods for the purpose of fortification, under standards of identity. Examples of the foods in which calcium fortification (in mg per pound (mg/lb)) is allowed, and the permitted levels of fortification in mg per pound (mg/lb), include: 136.115 *Enriched bread,* permits the addition of 600 mg/lb; 137.260 *Enriched flour,* may contain 960 mg/lb; 137.260 *Enriched corn meal,* may contain up to 750 mg/lb; 137.350 *Enriched rice,* may contain up to 1,000 mg/lb; 139.115 *Enriched macaroni,* 139.155 *Enriched vegetable noodle product,* and 139.165 *Enriched noodle products,* may contain up to 625 mg/lb respectively; 139.120 *Milk macaroni,* calcium-containing milk solids content not less than 3.8 percent of the weight of the finished product; 139.121 *Nonfat milk macaroni products,* finished product contains up to 25 percent calcium-containing, nonfat milk solids; 163.130 *Milk chocolate;* 163.135 *Buttermilk chocolate;* 163.140 *Skim milk chocolate;* and 163.145 *Mixed dairy product chocolates,* contain not less than 3.66 percent and up to 12 percent by weight calcium-containing milk solids.

2. Health Claims

In the **Federal Register** of August 4, 1987 (52 FR 28843), FDA published a proposal to amend the food labeling regulations to codify and clarify the agency's policy on the appropriate use of health claims on food labeling. The comments received on this proposal strongly opposed the use of the health claims. In the **Federal Register** of August 8, 1989 (54 FR 32610), FDA published an advance notice of proposed rulemaking that asked for public comment on how to reasonably permit the use of health claims on food labels that link food components to reduction of risk of chronic disease. In the **Federal Register** of February 13, 1990 (55 FR 5176), FDA withdrew the 1987 proposal and reproposed a regulation outlining how the agency would allow health claims. Calcium and osteoporosis were among the specific diet and disease relationships mentioned in these documents. However, on November 8, 1990, as stated above, Congress passed the 1990 amendments. This action is being taken in response to those provisions.

I. Evidence Considered in Reaching the Decision

The agency has reviewed all relevant scientific evidence on calcium and osteoporosis. This evidence included several recent Federal government reports: "The Surgeon General's Report on Nutrition and Health" (Ref. 1); the National Institutes of Health's (NIH) "Osteoporosis Report of the 1984

Consensus Development Conference on Osteoporosis" (Ref. 6); the NIH 1984 and 1986 "Osteoporosis—Cause, Treatment, Prevention" (Ref. 5); FDA "Proceedings of the National Conference on Women's Health Series—Special Topic Conference on Osteoporosis" (Ref. 10); the Department of Health and Human Service's (DHHS) "Healthy People 2000: National Health Promotion and Disease Prevention Objectives" (Ref. 11); the 1990 International Conference sponsored in part by NIH, "Consensus Development Conference: Prophylaxis and Treatment of Osteoporosis" (Ref. 7); and the DHHS "Osteoporosis: Research, Education, and Health Promotion" (Ref. 8).

Other authoritative documents used included: the National Academy of Science's (NAS) "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 2); the NAS "Recommended Dietary Allowances" (Ref. 3); the World Health Organization's (WHO) "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 9); the Life Science's Research Organization (LSRO) "Calcium and Osteoporosis Report" (Ref. 13); and the NAS "Nutrition During Pregnancy Report" (Ref. 12).

The agency considered the conclusions reached by these documents in light of the findings of human studies and new review articles in the scientific literature published subsequent to these documents. To assure that its review of relevant evidence was complete, FDA requested in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas identified in the 1990 amendments. The topic of calcium and osteoporosis was among the 10 subjects on which the agency requested information.

J. Comments in Response to FDA Request for Data and Information

In response to FDA's March 28, 1991 request for information other than that available in the authoritative documents cited in the **Federal Register**, the agency received comments from 17 sources. These sources included seven manufacturers of calcium supplements or calcium containing food products, three products or commodity interest groups, two consumer-public health interest groups, two academic institutions, two private citizens, and representatives of the Canadian government. These comments are described briefly here and will be considered, as appropriate, throughout the text of this document.

The majority of the comments supported a health claim proposal relative to calcium and osteoporosis, with only two comments, from a private citizen and from the Canadian government, opposing. A comment from a consumer advocate group urged FDA to be cautious and consider the consumer first and foremost when making its decision. Comments from an academic institution and from supplement manufacturers provided information purporting to demonstrate the effectiveness of a particular type of calcium supplement or food additive (fortificant) because of claimed superior bioavailability. The majority of the comments provided references or reviews of the calcium and osteoporosis relationship all of which were taken into consideration in preparing the science review.

II. Science Review

A. Federal Government and Other Reports

FDA identified seven documents in the **Federal Register** of March 28, 1991, that reviewed or made recommendations relative to the calcium-osteoporosis health relationship (Refs. 1 through 6, and 10). In addition, FDA considered the published conclusions of several recent government-sponsored conferences and reports and authoritative reviews (Refs. 7, 8, 9, 11, 12 and 13).

Comparing the conclusions from the first consensus conference on osteoporosis sponsored by NIH in 1984 (Refs. 5 and 6) to the most recent NIH-sponsored consensus conference held in October 1990 (Ref. 7), there is an evolution in thought concerning the importance of calcium intake to osteoporosis.

Changes in the recommended levels of calcium intake, and also changes in target population emphasis have in large part mirrored important clinical and epidemiological findings over the last decade. Initial emphasis was on a higher calcium intake for adults, with particular focus on postmenopausal women (Refs. 5 and 6). The 1984 NIH report suggested that all adults should consume more than the 1980 Recommended Daily Allowance (RDA) of 800 mg of calcium: "Adult women and probably adult men should have a total daily intake of 1,000 mg of calcium and women past menopause, not on estrogen therapy, need 1,500 mg daily" (Ref. 5).

NIH republished this document in 1986 (Ref. 5) with the following caveat: "It has not yet been proven by convincing scientific evidence that a high calcium intake will prevent osteoporosis." This qualification reflected the results of studies that failed to show that calcium intakes above the RDA or high calcium intake slowed bone loss in postmenopausal women (Refs. 109, 119 and 120).

The current focus presented at the 1990 "Consensus Development Conference: Prophylaxis and Treatment of Osteoporosis" shifts the emphasis on calcium intakes from older to younger individuals who are still actively laying down bone and recognizes that dietary calcium intakes below 1,000 mg per day of dietary calcium are adequate for adults (Ref. 7). The panel concluded that adequate calcium intake at all stages of life was a prerequisite for normal bone growth and attainment of peak bone mass. However, it also concluded that a high calcium intake is not as effective as a combination of adequate dietary calcium and estrogen therapy in blunting the accelerated bone loss during menopause. The panel also recognized that inadequate calcium intake is a risk factor for osteoprosis, citing a minimum intake of 800 mg calcium per day for all adults, and that "higher amounts are required in childhood, adolescence, pregnancy, lactation, and old age."

While the authoritative documents may present varying guidelines for adequate calcium intake, ranging from 800 to 1,500 mg per day for adults, they are unanimous in their recommendation that preventive efforts focus on maximizing peak bone mass (Refs. 1 through 3, 5, 6, 8 through 13). All of these documents emphasize that calcium intake is only one factor in this multifactorial disease, and that the exact nature of the association between calcium and osteoporosis is still unclear. The documents also agree that low calcium intake is a risk factor in the development of osteoporosis and may contribute to a lower peak bone mass or accelerate the rate of bone loss with aging (Refs. 1 through 3, 5, 6, 8 through 13). In addition, all these documents emphasize that during the interval of rapid bone loss that occurs early in menopause, both an adequate dietary intake in calcium and estrogen therapy are required and recognize the need for men and women to maintain adequate calcium intake later in life (Refs. 1 through 3, 5, 6, 8, through 13).

The 1987 FDA conference recognized that calcium is a threshold nutrient, i.e., deleterious effects may occur below a certain, unknown level of intake (Ref. 10). The NAS report on "Diet and Health: Implications for Reducing Chronic Disease Risk" emphasized, however, that potential benefits of calcium intakes above the RDA's to

prevent osteoporosis are not well documented (Ref. 2).

The recommendations for a particular level of dietary calcium intake are a key point of difference among the documents that set guidelines (Refs. 2, 3, 5, 7, and 11). "Recommended Dietary Allowances," published by NAS recommended an extra allowance of calcium to permit full mineral deposition through age 24, rather than through age 18, as in the 1980 edition of the calcium RDA (Ref. 3). The NAS made this change "to ensure a calcium intake that allows the development of each individual's genetically programmed peak bone mass during the formative years" (Refs. 2 and 3). Earlier recommendations of 1,000 to 1,500 mg calcium per day for peri- and postmenopausal women (Ref. 5) did not prevail, and the 1989 RDA for all adults of more than 25 years of age remained at 800 mg per day. This level for adults was recommended in the 1990 consensus conference, with higher, unstated levels for childhood, adolescence, pregnancy, lactation and old age (Ref. 7).

In summary, these documents show general agreement that, despite the lack of conclusive evidence, the data are sufficiently compelling to suggest that maintaining an adequate calcium intake during adolescent and early adult life may help to maximize peak bone mass and ultimately to reduce the risk of osteoporosis. Adequate calcium intake during the peri- and postmenopausal period in women and in elderly men is important, but alone, high calcium intakes will not prevent the accelerated rate of bone loss which normally occurs in peri- and early post menopause.

B. Recent Scientific Review of the Literature

1. Evidence Reviewed

A number of important studies have been published since the publication of the major authoritative and government documents described in the previous section. A thorough review of the literature from 1988 to March of 1991 revealed a number of review, commentary, and research papers dealing with various aspects of this subject. The criteria that the agency used to select studies required them to:

(1) Present primary, clinical data carried out in normal, healthy, nonpregnant, or nonlactating adolescents or adults;

(2) Be available in English;

(3) Include direct measures of bone status such as bone mineral density; and

(4) Include a measure or estimate of calcium intake or level of calcium supplementation.

The first criterion selected is consistent with the goals of the health claim in that it will be applied to a healthy normal population and is not to be a therapeutic claim. The second criterion is for convenience and was compelled by the timeframes imposed by the 1990 amendments. The third is consistent with the goal of the health claim in that it represents a direct measure of the health status of bone. The fourth criterion represents measurement of the nutrient for which evidence is sought to link adequate intake to the reduced risk of osteoporotic bone fracture.

FDA found that some of the papers identified in the literature search were not pertinent because they were carried out in subjects that were either not considered normal for their sex and age as a result of recent bone fractures or due to the diagnosis of osteoporosis or some other endocrine or dietary disorder (Refs. 14, 39, 40, 43, 56, 57, 84, 85, and 126). FDA did not consider others because subjects were inappropriately young (infants) (Refs. 81, 112 and 117), or the study failed to include a direct measure of bone status or calcium intake (Refs. 38, 62 and 135).

Furthermore, animal studies were not included in this review because "there is no completely satisfactory animal model of age-related or postmenopausal osteoporosis" (Ref. 2). While the extrapolation of animal studies to the human condition may not be appropriate, the results of studies in all animal models repeatedly show that low calcium intake causes reduced bone mass and osteoporosis (Refs. 46, 76, 77, and 127).

2. Criteria Used in Evaluating Studies

The criteria used in evaluating human epidemiological and clinical studies included:

(1) Reliability and accuracy of the methods used in food intake analysis and in assessing subjects, calcium intake for the day of study, lifetime, or their habitual intake, that is, the usual amount of calcium consumed;

(2) Choice of control subjects (e.g., age, sex, and race matched or matched for years since menopause);

(3) Representativeness of subjects;

(4) Control of confounding factors, particularly the level of activity or physical exercise must be controlled;

(5) The sensitivity of the endpoints measured, particularly with reference to the type of bone measured (cortical bone versus cancellous bone) or the bone site measured, (the rate of bone loss differs between types of bone and bone sites);

(6) Presence of recall bias and interviewer bias; and

(7) Degree of compliance and how compliance was assessed.

FDA evaluated the weaknesses and strengths of individual studies (see "Assessment" column of the Table). It then assessed the strength of the overall combined evidence (e.g., clinical intervention studies and epidemiologic studies) taking into account the strength of the association, the consistency of findings, specificity of the association, evidence for a biological mechanism, and presence or absence of a dose-response relationship. FDA's conclusions reflect the strength, consistency, and preponderance of data.

3. Evaluation of Evidence

FDA's evaluation of the totality of the recent human studies meeting the criteria outlined above is presented in Table 1. In addition, FDA considered a number of recent thorough reviews of this subject written by well-recognized experts which are not included in the Table (Refs. 16, 18, 20, 21, 22, 23, 26, 45, 49, 67, 69, 92, 103, 104, and 133).

To update and evaluate the impact of new findings on the earlier conclusions established by the authoritative and consensus documents, FDA sought to answer three questions:

First, do any of the studies present evidence documenting the role of calcium in achieving peak bone mass? The most frequently cited study supporting the importance of adequate calcium intake to the attainment of peak bone mass studied bone status and rates of hip fracture (cross-sectionally or at one point in time) in two areas of rural Yugoslavia (Ref. 96). The two communities were similar in several factors that could influence bone health and fracture rates (similar age, racial profiles, and levels of physical activity), but differed significantly in their usual calcium intake (about 400 versus 1,000 mg per day). Bone mass was significantly greater in both men and women by the age of 30 in the community with the higher calcium intake. More importantly, the incidence of hip fracture was significantly lower in the high calcium intake community with the higher peak bone mass. Experts concluded from this study that high life-long calcium intakes did not prevent bone loss since differences in bone mass as a function of age were constant in both groups, but it did increase peak cortical bone mass and significantly reduced the incidence of hip fracture later in life.

All the recent studies that examined subjects over a wide range of ages either

cross-sectionally (at one point in time) or longitudinally (several points over time) contributed some evidence relating to peak bone mass (Refs. 18, 25, 48, 60, 78, 82, 94, 97, 98, 99, 111, 123, and 125). Matkovic et al., (Ref. 97) demonstrated a trend toward an increase in bone density measured in two different skeletal sites in young teenagers who consumed higher levels of calcium over a period of 2 years relative to an age-matched control group. The controls consumed their usual, self-determined, or what is termed "habitual" calcium intake. However, the difference in bone mineral density between the high and low calcium groups was not statistically significant. This failure to show statistical significance could have been attributable to the small number of subjects studied (28 total). In another clinical trial, Baran et al., (Ref. 25) demonstrated no change in bone loss in women (30 to 42 years old) consuming 1,300 to 1,500 mg of calcium per day over 3 years, as compared to a control group that did not consume added dairy products and that showed a significant 2.9 percent loss of bone.

In a large supplementation study in women 35 to 65 years of age, Smith et al., (Ref. 123) demonstrated that daily supplementation of 1,500 mg calcium per day over 4 years in premenopausal women significantly reduced the loss of bone mineral relative to controls. Several cross-sectional studies in premenopausal women showed significantly higher bone density in women consuming higher calcium intakes (Refs. 60, 78, 94, and 111), yet others have failed to demonstrate a significant positive correlation between bone density and calcium intake (Refs. 19, 48, 86, 98, 99, and 125). In one study in men (Ref. 82), calcium intake was found to be an excellent predictor of bone density of the spine.

A critical concern in evaluating the effectiveness of dietary calcium intakes on bone density is that calcium intakes at the time of interview do not always correlate well with bone density measures that reflect a lifetime of a variety of influences. This lack of correlation between intake and bone density is particularly true for postmenopausal women (Refs. 94 and 124). However, in two studies where lifetime or historical calcium intake (intake estimated at age 20) was determined, there was strong positive correlation between high lifetime calcium (>500 mg per day) intake and bone mineral density of the mid and distal radius (Ref. 60) and the lumbar spine (Ref. 111). Cauley et al. (1988) showed that postmenopausal women who reported high lifetime intakes of calcium had significantly greater bone density than those who reported lower lifetime intakes (Ref. 36). Reliability of calcium intake estimates, either current, habitual, or lifetime estimates, is also a concern because these data are usually the weakest factor in these studies.

While the results of the more recent studies do not provide definitive evidence linking high calcium intake to achievement of maximum peak bone mass, they do provide evidence demonstrating a trend for increased bone mass in a carefully controlled, clinical trial (Ref. 97), and evidence of a strong positive correlation to bone density when lifetime calcium intakes were estimated (Refs. 36, 60 and 111). Moreover, the results of some of these studies demonstrate that a high calcium intake is beneficial in reducing the rate of bone loss in premenopausal women shortly after peak bone mass is achieved (Refs. 25, 78, and 111). A large intervention trial that utilized subjects over a wide range of ages showed a positive correlation between calcium intake and bone mass (Ref. 123). However, the results did not indicate whether this occurred through a maximization of peak bone mass or through a slowing effect on the rate of bone loss after skeletal maturity. Thus, the recent data, although not definitive, are sufficiently compelling to support the link between adequate calcium intake and achievement of peak bone mass.

The second question asked in reviewing these studies is whether added calcium or high calcium intake reduces the risk of fracture, or slows the rate of bone loss in younger or older subjects. Variation in results from the older studies underscores the lack of conclusive evidence that high calcium intake delays the development of osteoporosis. As stated in the NAS report on "Diet and Health Report: Implications for Reducing Chronic Disease Risk" (Ref. 2):

> Many published reports have shown either no relationship or only a modest relationship between dietary calcium and cortical bone mass, * * * evidence that calcium supplementation prevents trabecular bone loss associated with menopause is at best weak. There is strong evidence that calcium supplementation has a modest influence in preventing cortical bone loss, but * * * evidence relating calcium supplementation to fracture prevalence is scanty.

The lack of consistency in results in these older studies is the result in part of the various confounders that are also, regrettably, present in some of the more recent studies. Higher calcium intakes were shown to slow the rate of loss in premenopausal women consuming more dairy foods (Ref. 25) and in those consuming calcium supplements (Ref. 123). In postmenopausal women, calcium supplementation had no effect on spinal bone loss early in their menopause, but for women late in their menopause, the rate of bone loss was significantly reduced with calcium supplementation if initial habitual calcium intakes were lower than 400 mg per day (Ref. 47). This finding presents strong evidence supporting what others have shown—that spinal bone (predominantly cancellous bone at this site) loss in early postmenopause is less responsive to calcium supplementation than cortical bone of the hip or radius (Ref. 120). Stevenson et al., (Ref. 124) also found that dietary intake of calcium did not influence the rate of bone loss after 12 months of supplementation in women studied during the first 5 years of menopause.

In a large study examining women 35 to 65 years of age, calcium supplementation of postmenopausal women was shown to counteract a large portion of the annual bone loss that is attributable to menopause (Ref. 123). Others found that the rate of bone loss after 9 months of calcium supplementation (about 1,700 mg per day) in postmenopausal women was lower than in untreated controls, but the difference did not reach statistical significance (Ref. 113). In this study, when comparisons were made only between women within 10 years of the onset of menopause, there was a significant reduction in the rate of bone loss with calcium supplementation from dairy products. Others showed no relation between habitual calcium intake in postmenopausal women and bone mineral density of the radius in a cross-sectional study (Ref. 128) or of the radius, femoral neck or spine in a longitudinal study (Ref. 131). Habitual calcium intake exceeding 800 mg per day was not effective in preventing cortical bone loss in early menopause (Ref. 132).

It is apparent that a large part of the inconsistency observed in studies involving postmenopausal women may be the result of the overwhelming influence of the hormonal change early in menopause versus that of late menopause. With the exception of Polley et al., (Ref. 113), these findings suggest that subjects studied in early menopause are less responsive to increased calcium intake, but that women in late menopause are responsive. These findings suggest the

possibility that adaptational influences come into play later in menopause.

Another factor that may contribute to the inconsistency of study results is the differential response of the various skeletal sites measured. Fujita, et al., (Ref. 55) showed an increase in forearm bone density (primarily cortical bone at this site), but no change in spinal bone (mostly cancellous bone at this site), with calcium supplementation of subjects greater than 70 years of age (late menopause) for 2 years. Holbrook et al., (Ref. 72) found that the age-adjusted risk of hip fracture was associated with low estimates of dietary calcium intake in a large population of men and women aged 50 to 79 at the start of the 14-year study.

The results of the recent clinical trial of Nelson et al., (Ref. 102) underscores this point concerning the differential responses between cortical and cancellous bone to increased calcium intake. In this study, results showed a 1.1 percent loss of bone density in the femoral neck (cortical bone) in postmenopausal women consuming a moderate calcium intake, and a significant 2 percent gain in femoral neck bone density in women consuming a high calcium intake. However, calcium intake had no measurable effect on bone mineral density of the spine (cancellous bone) in this 12-month study.

Thus, as reported for earlier studies, inconsistencies also exist in the results of recent studies examining the effect of calcium intake on slowing the rate of bone loss. However, recognition of the facts that bone sites respond differently to high calcium intake, and that their responsiveness to calcium varies with time after menopause, requires that any evaluation of these studies place less weight on those that found no effect of calcium on spinal bone density in early menopause because of what is thought to be the overriding effect of estrogen withdrawal. Given the current understanding, evidence becomes more compelling in support of the hypothesis that adequate calcium intake slows the rate of bone loss in general in perimenopausal women (Refs. 25, 78, 111, and 123) and in predominantly cortical bone sites in women late in menopause (Refs. 36, 47, 55, 102, and 113).

The third question considered was whether or not any of the studies showed a threshold effect for the level of calcium intake associated with changes in bone mass. The concept that calcium is a threshold nutrient was discussed in the FDA sponsored conference on osteoporosis in 1987 (Ref. 10). Concern focused on the lower threshold suggesting that low dietary calcium is a permissive element rather than a causative element in the development of osteoporosis (Ref. 65). Only recently have the upper limits of the effect of calcium intake been explored.

Kanders et al. (Ref. 78), in their cross-sectional study, showed that bone mineral density of the spine did not increase with calcium intakes above 600 to 1,000 mg per day, which implies an upper limit of calcium intake on optimizing peak bone mass in premenopausal women. Halioua and Anderson (Ref. 60) observed similar results at levels above 800 mg of calcium per day in postmenopausal women. These studies support the concept of an upper level of calcium intake beyond which no benefit to bone status can be observed.

The more important aspect of the threshold concept is the lower level, the level of calcium intake below which bone health is impaired. The findings of Dawson Hughes et al. (Ref. 47), suggest that for women in their late menopause this level is probably around 400 mg per day. This question clearly needs further research and careful definition.

Another important consideration is the speculation presented by Kanders and her coauthors (Ref. 78) concerning their findings that bone mineral density of the spine can be influenced by both physical activity and optimal calcium nutrition during the period of consolidation in young adult women. The authors speculate that if their findings of an increase in spinal bone mass were applied longitudinally (over time), one may be able to delay the development of osteoporosis and related bone fractures for an estimated 10 years (Ref. 78).

To summarize these new findings, some aspects of the relationship between calcium and osteoporosis remain unclear, but with the growing understanding of how other factors confound these results, it is becoming increasingly evident that calcium intake has a significant impact on bone health. Study results must be interpreted in light of new findings concerning the sensitivity of specific bone sites to diet, the limitations of the effect of diet during early menopause, and the inherent weaknesses of measuring or estimating habitual, current, lifetime or historical calcium intake, the independent variables in the recent studies reviewed here. This issue of accurate determinations of calcium intake is discussed at length in the LSRO report on "Calcium and Osteoporosis" (Ref. 13), where the authors emphasized that the weakest point in determining the relationship between calcium intake and changes in bone mass rests with the inadequacies of determining this independent variable, notably an accurate and reliable estimate of calcium intake. It is now apparent that calcium's effect on retarding bone loss in postmenopausal women may be influenced by habitual calcium intake, where persons with lower habitual intakes show the greatest response (Ref. 47). Thus, recent findings were generally consistent and strengthened the conclusions and guidelines set forth in the government and authoritative documents.

III. Decision to Accept Health Claim

A. Public Health Context

Osteoporosis is a major health concern of the elderly, particularly women, since 25 to 30 percent of all postmenopausal women are affected (Ref. 18). The etiology of this disease is multifactorial with sex and race being the strongest influences (Ref. 118). Low calcium intake has been identified as a risk factor, although controversy exists concerning the extent of its effect (Refs. 65, 79, and 80). Many experts argue that a lifetime low calcium intake, that is at levels below the level of obligatory loss (calcium that the body must lose every day in fecal secretions and urine), which is usually 150 to 300 mg per day but which some have defined as 300 to 400 mg per day, may result in low peak bone mass and above average loss of bone mass in adults (Refs. 8 and 87).

B. Dietary Calcium Intake

National food intake surveys (Refs. 35, 54, and 105) provide evidence identifying calcium from dietary sources as a problem nutrient in a subpopulation at risk for osteoporosis, namely women between 11 through 35 years of age. These surveys show that men have a greater intake of calcium than women largely as the result of greater total caloric consumption by men rather than as a result of differences in types of foods consumed. These surveys suggest that as early as 9 years of age, mean calcium intake for women is well below the RDA and remains low from early to late adulthood. These dietary data alone, however, are insufficient to establish calcium status of women 9 years and older with low dietary calcium intakes.

C. Sources of Calcium

For the general population, diet is the primary source of calcium (Ref. 63). However, for some individuals, calcium in vitamin/mineral supplements or contained in drinking water or in certain chronically used medicines are

significant sources of their total daily calcium intake (Ref. 63). Calcium is not uniformly distributed in the food supply. Milk and milk products are among the richest sources of calcium and have been shown in recent surveys to contribute approximately 40 percent of the total dietary calcium ingested by adult men and women and nearly 65 percent of the daily calcium in children (Ref. 54).

D. Guidelines for Calcium Intake

The National Academy of Sciences set the RDA for men and women 19 years of age and older at 800 mg per day in 1980. However, acknowledging that greater calcium intake is needed during the period of consolidation to maximize peak bone mass, NAS redefined the adult age range to include men and women 25 years and older in the 1989 revision (Ref. 3). Because of differences in physiologic need, it set the RDA for adolescents 11 to 24 years of age at 1,200 mg per day; for children (1 to 10 years) at 800 mg per day; at 540 mg for infants (0.5 to 1 years); and at 360 mg per day for neonates (Ref. 3). By definition, the RDA for any nutrient contains a large margin of safety, representing adequacy for 95 percent of the healthy normal population (Ref. 3).

E. Safety of Calcium Guidelines

Calcium toxicity is not generally recognized as a problem in the United States population because normal healthy people have intrinsic control mechanisms that prevent excessive serum levels (Refs. 22, 63, and 73). The main control occurs at the level of absorption because calcium absorption becomes less efficient as calcium intake increases. The usual side-effects that are the hallmark of calcium toxicity include hypercalcemia (elevation of calcium in the blood) which has neurologic and neuromuscular effects, excessive calcium loss in urine, formation of kidney stones, and deposition of this mineral in soft tissue.

In 1979, an expert panel reviewed the data on the safety and effectiveness of various vitamin and mineral products and concluded that "calcium intakes ranging from 1,000 to 2,500 mg daily do not result in hypercalcemia in normal individuals" (Ref. 53). Calcium toxicity is, however, a concern for individuals who for some physiologic reason hyperabsorb calcium from the gut or from filtered urine. Most common among these individuals are those with a family history of kidney stones. For the normal healthy population, the guidelines for calcium intake (RDA) are considered well within the limits of safety.

F. Rationale Leading to the Decision to Accept Health Claim

FDA has proposed no specific provisions pertaining to the agency's assessment of conformance with the standard. Instead FDA envisions that to satisfy the scientific standard, a health claim must be supported by a sound body of scientific evidence that establishes the relationship between a dietary component and a particular disease or health related condition. The data must persuade FDA that the proposed claim is valid, and that the benefits featured in the claim pertain to the general U.S. population or to a significant segment of the U.S. population. Thus, the body of scientific data must be strong. A few unconfirmed studies, preliminary or incompletely documented data, or significantly contradictory findings do not constitute a sound body of evidence.

The standard requires that significant agreement exist among qualified experts that the claim is valid. "Qualified experts" include individuals whose training and experience have produced a general or specific scientific expertise in the diet/health topic being considered for a specific claim. FDA is not proposing to define "significant agreement" among experts because each situation may differ with the nature of the health benefit. The agency believes that any specific definition of such agreement might prove arbitrary when viewed in the light of the multiplicity of potential health benefits and the widely variable nature of expertise required to evaluate the significance of these benefits. Instead, FDA intends to use the discretion granted it by the 1990 amendments to assess the degree of agreement on a case-by-case basis. Nevertheless, FDA will take the full range of opinions among qualified scientific experts on a specific claim into account in determining whether significant agreement exists.

FDA does not prescribe a specific set, type, or number of studies as being sufficient to support a health claim for the procedure to assess conformance with the scientific standard. The agency will consider all relevant data on a topic, including clinical studies (human studies conducted in a controlled clinical setting), epidemiological data (data from uncontrolled human populations), and animal studies. However, the type, quality, and relevance of a study from which data are derived have an important bearing on how much weight is placed upon the data. Because of the many unknowns about the direct effect of a dietary substance on health or disease relative to the effects of other environmental and genetic variables, and given the limitations on the ability to accurately quantify dietary intake for some substances, indirect approaches are usually required to assess the scientific weight of a set of data.

The overriding principle will be to determine whether there are consistent results from different types of well-conducted human studies by different investigators in different populations. The strengths and weaknesses of each individual study will be evaluated. When experiments with animal models are appropriate, consistency of results between human and animal studies will also be considered. Such results will be interpreted in the light of any available evidence on the biological mechanism of the substance-disease relationship, evidence of a dose-response relationship, and similarity of the test substance with the nutrient or food component of interest. The significance of the disease from a U.S. public health standpoint will be also evaluated. In sum, FDA intends that its judgments concerning the overall quality of available data, the appropriateness of the study design, the consistency across different types of studies and laboratories, and the conclusions derived from the total body of evidence will be based on the generally recognized scientific procedures and principles that are most appropriate to the issues being addressed.

FDA has reviewed the conclusions in the Federal government and other documents (Refs. 1 through 13) and in recent review articles on calcium intake and osteoporosis (Refs. 16, 18, 20, 21, 22, 23, 26, 45, 49, 67, 69, 92, 103, 104, and 133). It also examined the totality of pertinent human studies published since the NAS report on "Diet and Health: Implications for Reducing Chronic Disease Risk" (Refs. 18, 25, 36, 47, 48, 55, 72, 78, 82, 86, 94, 97, 98, 99, 102, 111, 113, 123, 124, 125, 128, 131, and 132). In addition, the agency considered all comments received in response to the notice of request for scientific data in the **Federal Register** of March 28, 1991, on the link between calcium intake and osteoporosis. Based on the overwhelming concurrence among the experts in this area, FDA proposes to allow a health claim on the label of products that meet the regulatory specifications set forth in proposed § 101.72. The health claim will relay the message that an adequate intake of calcium throughout life may delay the development of osteoporosis and ultimately reduce the risk of bone fracture in some individuals later in life.

The tentative decision to allow the proposed claim is based on significant agreement among experts in the field concerning three important conclusions. First, experts conclude that maintenance of adequate calcium intake during all stages of life is important to normal bone health and to optimal peak bone mass, and that optimizing bone mass at skeletal maturity (at about 35 years of age) may help to delay the onset or reduce the risk of osteoporosis and related bone fracture. To produce definitive evidence directly linking calcium intake to optimized bone mass and ultimately to reduced risk of osteoporosis and the delayed onset of bone fracture would require a 50- to 60-year-long study. However, there is overwhelming agreement among experts and among the authoritative documents reviewing this subject that adequate calcium intakes are important in optimizing bone health and therefore in reducing the risk of osteoporosis. With a higher peak bone mass, individuals have a lower risk of reaching the critical fracture threshold. Review of recent data did not refute this conclusion; it strengthened it, demonstrating a trend toward increased bone mass with higher calcium intake.

Secondly, for older adults, experts have concluded that maintenance of adequate dietary calcium is crucial to slowing the rate of bone loss, notably during the first decade following menopause. However, for the postmenopausal women, calcium alone will not significantly slow the rapid rate of bone loss that occurs shortly after menopause. The recent literature also supports this conclusion with rigorously controlled intervention studies or studies with more accurate measures of estimated calcium intake. These recent studies demonstrate the bone loss-slowing effects of calcium on bone sites known to be responsive to this nutrient and in women late in menopause, when the overriding effect of estrogen withdrawal does not mask the beneficial effect of adequate dietary calcium.

Thirdly, bone experts have concluded that the recommended calcium intake levels are safe and there is a growing recognition that RDA guidelines are adequate and can be reached within the context of the total daily diet. Current evidence supports the concept that a threshold nutrient intake level exists for calcium, below which bone health is jeopardized, and the concept of an upper limit of intake, above which bone derives no further benefit (Refs. 10, 47, 64, 78).

Maintaining an adequate calcium intake is a concern in certain segments of the United States population. Estimates of daily calcium intake for men and women determined in the most recent nationwide surveys show that for men, mean calcium intake closely approximates the guideline for intake throughout their life span (Refs. 35 and 105). However, both surveys show that the average calcium intake for women falls well below the 1980 RDA guideline and remains below the RDA with increasing age. This low calcium intake in conjunction with high rates of osteoporosis in the elderly, female, U.S. population is of greatest concern in adolescent and young adult women, an age group with the highest calcium requirement and who comprise the population at greatest risk of developing osteoporosis (Refs. 2 and 3). Others at risk of osteoporosis because of low calcium intake include those individuals, notably women and elderly men, whose calcium intakes may be less than the amount of calcium that is naturally required to be lost each day in urine or in gastrointestinal secretions or sweat (Ref. 8). No individual should consume less calcium than they naturally lose in a day which is normally about 200 mg or in the range of 150 to 300 mg, but may range between 300 to 400 mg per day (Refs. 3, 8, 66, and 88). A decision to allow a health claim would help the public to meet one of the dietary goals established in the federally sponsored "Healthy People 2,000: National Health Promotion and Disease Prevention Objectives" (Ref. 11), since the labels will facilitate the recognition of calcium-rich products.

The newer evidence is supportive of, and does not contradict the scientific consensus reached earlier. However, from the findings of the documents and studies cited above, the role of calcium in reducing the risk of osteoporosis is most relevant for those subpopulations at greatest risk because of sex, race, or family history.

IV. Description and Rationale for Components of Health Claim

A. Relationship Between Calcium and Osteoporosis

Based on the totality of the evidence and significant scientific agreement among experts qualified by training and experience to evaluate such claims, FDA has tentatively determined that there is adequate scientific evidence that consumption of an adequate calcium intake throughout life may optimize peak bone mass during adolescence and early adulthood and help to slow the rate of bone loss later in life. By maximizing the amount of bone present in old age through higher peak mass and subsequent slower rate of loss, one may reduce the risk of osteoporosis and related bone fractures.

In proposed § 101.72(a), FDA describes the relationship between calcium and osteoporosis. Experts have identified low or inadequate calcium intakes as one of many risk factors in the development of osteoporosis (Refs. 21, 63, 95, and 118). Inadequate calcium intake is thought to contribute to low peak bone mass (Ref. 10). Peak bone mass is the total quantity of bone present at skeletal maturity which experts believe has the greatest bearing on whether a person will be at risk of developing osteoporosis and related bone fractures later in life (Refs. 21, 64 and 118). The rate of bone loss after skeletal maturity also influences the amount to bone present at old age and also influences an individual's risk of developing osteoporosis (Refs. 21 and 118).

Experts conclude that an adequate calcium intake maintained throughout life, particularly during adolescence and early adulthood, will help to achieve one's genetically programmed upper limit of bone density (Refs. 2, 3 and 64). The rationale linking adequate calcium intake and optimal peak bone mass to the reduced risk of osteoporotic fracture relates to the fact that all individuals lose bone as they age. However, those individuals with more bone present at maturity take longer to reach the critical reduction in bone mass at which bone fractures with little trauma (Ref. 20).

Bone density later in life depends on both the amount of bone made during growth (peak bone mass) and the subsequent rate of bone loss after maturity. Maintenance of an adequate calcium intake later in life has been shown to be important in reducing the rate of bone loss particularly in the elderly (Refs. 63 and 118) and in women during the first decade following menopause (Refs. 47, 63, 67, 102 and 118).

In proposed § 101.72(d)(3), FDA requires that the health claim state the mechanism of optimizing peak bone mass during adolescence and early adulthood and the mechanism of helping to slow the rate of bone loss at menopause in women and in the elderly by adequate consumption of calcium. These mechanisms link calcium intake to the disease state of osteoporosis. In the label statement, FDA proposes to allow the concept of achieving peak bone mass to be conveyed to the public with a simpler phrase such as "build and maintain good bone health."

B. Significance of Calcium

In proposed § 101.72(b), FDA is describing the significance of calcium in affecting osteoporosis. The agency has tentatively identified those factors that describe the multifactorial nature of osteoporosis and has identified those risk factors that identify subpopulations of individuals who would most benefit from a lifelong, adequate calcium consumption. In proposed §§ 101.72(b) and 101.72(d)(2), FDA tentatively proposes to require specific identification of those individuals within the general population at greatest risk of developing osteoporosis and for whom the proposed health claim would have greatest benefit. These individuals include Caucasian and possibly Asian women and adolescent girls between 11 and 35 years of age, men and women with family histories of osteoporosis, menopausal women (who may be identified as middle-aged women in the label statement), and elderly men and women.

Proposed § 101.72(d)(2) also tentatively requires that the health claim not convey the misconception that the risk of osteoporosis is equally applicable across the general United States population. Many individuals in the U.S. population are at much lower risk for the development of osteoporosis than the target populations described above. This fact was presented to the public as early as 1984, when NIH identified those individuals at greatest risk of osteoporosis in their publication, "Osteoporosis: Cause, Treatment, Prevention" (Ref. 5). Being Caucasian was cited as the third greatest risk factor following being a woman and early menopause (Ref. 5). The document further stated that "white women are at higher risk than black women and white men are at higher risk than black men and oriental women are also thought to be at greater risk for the disease, but there is not enough data to confirm this" (Ref. 5).

African Americans have a significantly lower incidence of osteoporosis-related bone fracture than Caucasian Americans (Refs. 28, 41, 118, and 136). This lower incidence of osteoporosis in African Americans is attributed to a significantly higher peak bone mass than Caucasian Americans (Ref. 28). Asian Americans are reported to have lower bone mineral content of the radius than age-matched Caucasians (Refs. 21 and 134). However, recent findings show that hip fracture rates among Asian Americans are approximately half that of Caucasians (Ref. 121). Data on time trends in the incidence of hip fractures are available for Caucasians and to a limited extent Asian populations (Ref. 136). These data indicate an increase in the incidence of hip fractures in Asian women and men. Information on the bone density and fracture incidence among Hispanics in America is limited but reported to be lower than Caucasians (Ref. 136).

The vast majority of studies examining calcium intake and bone status exclusively use Caucasian subjects (Ref. 13), largely because the incidence of the disease is higher in Caucasians. In addition, surveys indicate that other races such as African Americans have a much lower calcium intake purportedly because of their inability to digest the milk sugar, lactose (lactose intolerance) (Refs. 50, 51 and 63). In light of the facts that African Americans have genetically higher peak bone mass, significantly lower incidence of osteoporosis-related bone fracture, lower calcium intakes, and significantly higher incidence of lactose intolerance, they are at much lower risk of developing osteoporosis and presumably would not benefit by increasing their calcium intake. Moreover, with milk and milk-related products contributing the greatest portion of dietary calcium to daily calcium intake (Ref. 54), trying to consume because of dietary calcium may result in greater incidence of discomfort due to lactose intolerance. A similar statement could be made for other racial groups such as Hispanic Americans, although far less data is available concerning the incidence of osteoporosis-related bone loss in this population, but they have been identified as having low calcium intakes and lactose intolerance (Refs. 51, 63 and 137).

FDA does not want to mislead those individuals within the population for whom there is no apparent benefit to bone health from consuming relatively higher levels of calcium over a lifetime. However, this is a difficult concept to present on a label claim without confusing the general population. Thus, the agency solicits comment on alternative ways of presenting this information and tentatively proposes in § 101.72(d)(2) that the claim shall not convey the misconception that the risk of osteoporosis is equally applicable to the general United States population, and that the subpopulation clearly at greatest risk is identified. This subpopulation includes Caucasian females but may also include Asian females. The agency has proposed that the subject of appropriate population targeting for the calcium and osteoporosis health claim, and how to most clearly present this information to the public, as an objective of the focus groups assembled to examine the impact and interpretation of the new labeling.

Men have greater peak bone mass than women across all races, and in addition men do not undergo the rapid rate of bone loss that women experience at the onset of menopause (Refs. 74 and 136). These factors contribute to men having a significantly greater bone mass in later years than women. These differences in the rate of loss of bone and in the total bone mass at maturity help to explain the significantly lower incidence of osteoporosis in men compared to women (Refs. 20 and 118)

Calcium intake is not the only recognized risk factor in the development of osteoporosis. Other factors include a person's sex, race, hormonal status, family history, body stature, level of exercise, general diet, and specific life style choices, such as smoking and excess alcohol consumption. Experts have identified those individuals at greatest risk of developing osteoporosis as being older, Caucasian or Asian, female and menopausal (natural or premature), thin and slight in stature with a relatively sedentary lifestyle (Refs. 10, 83, 109 and 118). Cigarette smoking and high alcohol intake also increases individual risk for the development of osteoporosis (Refs. 64 and 83).

In proposed § 101.72(d)(1), FDA tentatively proposes to require that the claim make clear that calcium is not the only recognized risk factor in the multifactorial bone disease, osteoporosis, by identifying specific other risk factors including sex, race, family history, and the need for adequate exercise and a well-balanced diet. Because osteoporosis is multifactorial, FDA believes that it is not possible to quantitate the amount of reduced risk of osteoporosis that results from adequate calcium intake throughout life. Therefore, FDA is proposing in § 101.72(d)(4) to require that a claim not quantative the degree of reduced risk.

In proposed § 101.72(d)(5), FDA is providing that a claim shall state that a total dietary intake of calcium of greater than 200 percent of the RDI (1,800 mg) has no known additional benefit. This provision reflects the findings discussed above that calcium intakes of 800 to 1,000 mg of calcium a day appear to be the upper level of calcium intake beyond which no benefit to bone status has been observed (Refs. 60 and 78). The agency has tentatively set this level at 1,800 mg a day to reflect that higher

amounts of calcium are needed in old age (Ref. 7).

C. Proposed Qualifying Levels of Calcium

In proposed § 101.72(c)(2), FDA is proposing to identify the calcium content levels needed to qualify for a health claim. In the companion document on general requirements for health claims, published elsewhere in this issue of the **Federal Register**, FDA has tentatively concluded that for nutrients for which increases in intake are associated with a desirable health outcome, FDA's proposed criterion for a "high" amount of a nutrient shall be the basis for determining the minimum amount of the nutrient that must be in a food for the food to be eligible to bear a health claim. This criterion is described in the proposal on nutrient content claims, published elsewhere in this issue of the **Federal Register.** For calcium, a product must contain a minimum of 20 percent of the proposed RDI for calcium (see companion document on Mandatory Nutrition Labeling published elsewhere in this issue of the **Federal Register**) or 180 mg of calcium per reference amount customarily consumed and per labeled serving to meet this criterion. This amount may either be naturally occurring in foods or may be added to a food or a supplement.

In proposed § 101.72(c)(1), FDA is requiring that a product satisfy all the requirements of § 101.44. Among these requirements is that if a calcium-containing ingredient is added to a food or supplement, the use of that ingredient must be demonstrated by the proponent of the claim to be safe and lawful under the applicable food safety provisions of the act. This showing can be made in a number of ways, including a showing that the use of the substance is:

(1) GRAS as listed in 21 CFR part 182, or in accord with the general principles stated in 21 CFR 170.30, provided that the use of the ingredient remains at individual consumption levels consistent with its use prior to January 1, 1958; or

(2) Affirmed as GRAS in 21 CFR part 184, approved for use as a food additive, or subject to a sanction or approval granted by FDA or the U.S. Department of Agriculture (USDA) prior to September 6, 1958.

In addition, FDA is proposing in § 101.72(c)(3) that the calcium content of the product, either added or natural, be assimilable as required in the calcium and iron enrichment of cereal-grain products (21 CFR part 137). Benefits of calcium intake from foods and supplements can only be obtained if the calcium is available for metabolic use by the body. There is strong evidence that dietary intake of protein, fiber, phosphorus, and certain naturally occurring and added substances such as oxalate, phytate, and fiber interfere with calcium absorption or metabolism (Refs. 15, 63, 69, and 71).

FDA is concerned about the bioavailability (ability to assimilate) of the calcium contained in products that make a health claim. It would be misleading to put a health claim for a substance on a food if consumption of that food will not provide the substance. Spinach illustrates the concern that products contain bioavailable calcium. While spinach is rich in calcium, it is not an appropriate candidate for a health claim on its label because of its established poor calcium bioavailability (Ref. 70). FDA recognizes the difficulty of assessing mineral bioavailability in humans where inter-individual variation is a significant confounding factor. For this reason, FDA requests comments on how calcium bioavailability can be assessed without bias in products under review for health claim eligibility. More specifically, the agency requests comments that would flag other foods or food components that are good sources of calcium but have poor bioavailability. These solicited comments should also consider products that are processed in such a way that the processing alters the bioavailability. For example, yeast enzymatic cleavage of phytase during the leavening of bread alters calcium bioavailability (Ref. 15). The agency also requests comments on how to address the issue of bioavailability for calcium supplements (Refs. 66, 69, 108 and 122).

D. Proposed Disqualifying Components of Products

Calcium bioavailability means both absorption and tissue utilization of calcium. Therefore, the presence of food or supplement components that cause increased urinary or fecal excretion, or impair the utilization of calcium by bone, would disqualify a product for a calcium-osteoporosis claim. Thus, FDA is proposing in § 101.72(c)(4) to disqualify calcium supplements from a health claim if they fail to meet the United States Pharmacopeia standards for disintegration (Refs. 122, 129 and 130) and dissolution (Refs. 122, 129 and 130). These products should not contain any substance, such as a salt of orotic acid, that is known to be harmful and to have adverse effects on calcium metabolism or on nutrient status (Refs. 42, 61 and 75).

High levels of dietary phosphorus and protein significantly adversely affect the metabolism and obligatory loss of calcium, respectively (Refs. 2, 3 and 17). The agency, however, is not proposing to disqualify high protein products from bearing a calcium claim. Like calcium, protein is not ubiquitously distributed in our food supply and is richest in specific food sources (Refs. 27 and 110). Some of these protein rich foods, such as milk or milk products, contribute more than half the calcium and protein intake of some individuals, notably children. Thus, relatively few foods are sources of calcium and protein, forcing consumers to be selective to meet the nutritional needs for both calcium and protein. It would be misleading to disqualify a product that is both rich in calcium and protein based on the protein's effect on urinary excretion of calcium without knowledge of what contribution this product made to the consumer's total protein intake.

While only a few foods are rich in calcium and protein, nearly all foods contain phosphorus as either a natural component or as an ingredient added during processing (Refs. 17, 31 and 58). Thus, unlike for calcium, consumers do not have to be selective to meet their daily phosphorus needs. In contrast to the low calcium intakes that have been reported for the majority of American women, phosphorus consumption is high for both men and women (Ref. 31). National nutrition surveys indicate that the diets of teenagers and young adults are relatively high in phosphorus and low in calcium (mean daily intake of 500 to 600 mg per day of calcium and greater than 1,000 mg per day of phosphorus) (Ref. 105).

According to NRC's 1989 report "Recommended Daily Allowances," the desired calcium to phosphorus ratio of the United States diet is 1:1, but the ratio of actual food consumption patterns differs with age (Ref. 3). Infant consumption patterns produce a ratio of 2.3:1 for human milk, that decreases with age to 1:1.8 for adults but may be as low as 1:4 for individuals with low intake of dairy foods or green vegetables (Ref. 3). Protein rich foods such as milk, meat, poultry, fish, cheese, and cereal grains contribute the majority of phosphorus in the American diet, but highly processed and convenience foods can contribute 20 to 30 percent of the daily phosphorus as food additives (Ref. 58). Evidence shows that phosphorus intake may be underestimated as much as 15 to 20 percent, because the phosphorus supplied by numerous food additives in processed foods are not always accounted for in tables of food composition (Ref. 106).

FDA is proposing that high levels of phosphorus (naturally occurring or added) in conventional foods or supplements that result in calcium to

phosphorus ratios lower than 1:1 will disqualify the product from bearing a calcium/osteoporosis health claim. FDA's tentative decision to identify phosphorus as a disqualifying nutrient is based on the ubiquitous distribution of this mineral in the food supply, the low ratio of calcium to phosphorus that typifies current intake patterns, and current evidence demonstrating that high levels of dietary phosphorus coupled with low dietary calcium adversely influence hormonal factors that regulate calcium and bone metabolism (Refs. 17, 21, 29, 32, 46, 93, 114, and 116). Recent studies in humans show that high intakes of phosphorus compared to calcium typically observed in the United States diet will produce changes in serum calcium and bone regulating hormones that may adversely affect peak bone mass (Refs. 17, 21, 31, 32, 114, 115 and 116). This evidence is supported by findings from a variety of animal models demonstrating that diets high in phosphorus and relatively low in calcium result in changes in calcium regulating hormones that adversely affect bone formation and stimulate bone resorption, and ultimately bone loss (Ref. 46).

To qualify for the health claim, FDA tentatively proposes in § 101.72(c)(5) that a product should not contain more phosphorus than calcium on a weight per weight basis. For those products that contain just 20 percent of the proposed RDI for calcium (about 180 mg of calcium), the product must contain no more than 20 percent of the RDI for phosphorus (about 180 mg) in a single serving or recommended daily supplement intake to be eligible to bear a health claim. This level is consistent with the 1:1 ratio of calcium to phosphorus set by the RDA for calcium and phosphorus (Ref. 3) and previous nutritional quality guidelines promulgated by FDA. This proposed disqualifying level of phosphorus is consistent with the nutritional guidelines set forth in § 104.47(d)(4): "When technologically practicable, product components and ingredients shall be selected to obtain the desirable calcium to phosphorus ratio of 1:1."

Other nutrients, such as sodium, also have adverse effects on calcium metabolism when high dietary levels are consumed (Refs. 59 and 135). However, sodium and other nutrients in high levels may disqualify a product from the claim because of their association with diseases other than osteoporosis. FDA has proposed disqualifying levels for fat, saturated fat, cholesterol, and sodium in proposed § 101.14. In proposed § 101.72(c)(1), as stated above, FDA proposes that all requirements for health claims as defined in proposed § 101.14 must be met for a product to bear a claim relating calcium intake to osteoporosis. Disqualifying nutrient levels are discussed in the proposal on general principles for health claims published elsewhere in this issue of the **Federal Register.**

Given the proposed conditions and requirements for a product to bear a health claim relating calcium intake to reduced risk of osteoporosis discussed above, some typical foods that would qualify for this claim include servings of: lowfat yogurt, 1 and 2 percent fat milk, skim milk, cultured buttermilk, 2 percent lowfat chocolate milk and tofu (Ref. 44). As discussed in the preamble to the proposal on general principles for health claims, FDA finds no basis to provide an exception to the disqualifying levels to permit a calcium and osteoporosis claim on whole milk.

To assist manufacturers in formulating a health claim, FDA is providing a model message in the proposed regulation.

V. Appendix to the Preamble—Consumer Summary on Dietary Calcium and Osteoporosis

The following appendix is a proposed consumer summary on dietary calcium and osteoporosis. FDA solicits comments on this document as explained in the proposal on general requirements for health claims published elsewhere in this isue of the **Federal Register.**

Appendix—Consumer Summary on Dietary Calcium and Osteoporosis

Dietary Calcium and Osteoporosis

Under the provisions of the recent Nutrition Labeling and Education Act, manufacturers may put clear information on the food label about the relationship between a nutrient, such as calcium, and a disease or health-related condition. To prevent consumers from being misled, the Food and Drug Administration (FDA) allows only truthful label statements about diet and health relationships that are firmly supported by current scientific evidence. There is agreement that the evidence is strong enough to allow a health claim about the relationship between dietary calcium and osteoporosis.

Many consumers have said that health claims on food labels could be useful to them in making improvements in their diets. However, label space is often limited. Therefore, this pamphlet provides information about the diet and health claims that supplements what you may see on food labels.

In addition to dietary calcium and osteoporosis, FDA is allowing health claims about the relationship between sodium and hypertension, saturated fat and cholesterol and cardiovascular disease, fat and cancer, and _____. For information about these other diet and health relationships, write to: [TO BE INSERTED].

What is Osteoporosis?

Osteoporosis is a disease condition in which reduced bone mass causes the bones to fracture easily. The disease occurs in both sexes but is more common among older women.

Why is There Concern About Osteoporosis?

Osteoporosis is a public health concern because from 15 to 20 million Americans are affected. Osteoporosis reduces the mobility and quality of life of the people affected. The disease is responsible for about 50,000 deaths annually, and substantial health care costs are associated with it.

One-third of women 65 years and older have spinal vertebrae fractures, the most common break associated with osteoporosis. Vertebral fractures are often undetected, and few women identify the height loss that results as due to osteoporosis. Many elderly men and women suffer hip fractures as a result of osteoporosis, which few people associate with this disease.

Osteoporosis contributes to some 1.3 million bone fractures per year in persons 45 years and older. Spinal fractures are painful, but hip fractures may have more serious effects and usually result in hospitalization.

What is the Cause of Osteoporosis?

Osteoporosis is a complex disease, and why it develops in some people is not entirely understood at this time. The factors that make a person most at risk for developing the disease are increased age and being a female (particularly when loss of the hormone estrogen occurs) of the Caucasian or Asian race. However, several lifestyle factors over which people have greater control are also believed to be associated with a decreased risk of its development. These include consuming an adequate amount of dietary calcium and getting enough exercise, especially during the bone-forming years; eating a balanced diet; not smoking cigarettes; and either not drinking alcohol or doing so in moderation.

The exact nature of the association between calcium and osteoporosis is under active research. Scientific experts

agree that consuming an adequate amount of calcium in your diet throughout life is important to bone health.

The maximum amount of bone that a person can build is determined by heredity. Bone continues to be added to the skeleton until about 35 years of age, at which time skeletal maturity occurs. Scientists agree that adequate dietary calcium during the bone-forming years is important to building an optimal amount of bone (called "peak" bone mass). Building optimal bone mass through a balanced diet, including adequate calcium, until skeletal maturity occurs may help to delay the onset of or limit the chance of developing osteoporosis later in life.

Bone experts also agree that, for adults in midlife or older years, maintaining adequate dietary calcium is crucial to slowing down the rate of bone loss that naturally occurs at that time. Getting enough dietary calcium is especially important during the first decade following menopause. However, for women at the onset of menopause, dietary calcium alone will not sufficiently slow the rate of bone loss, which is especially rapid early in menopause. At menopause, estrogen replacement therapy is the most effective means to reduce the rate of bone loss, and the risk for fractures.

Low calcium intakes are of greatest concern in adolescent and young women who have high calcium requirements. Young women who do not meet their calcium need during these age periods are most at risk of developing osteoporosis later in life. Postmenopausal women and elderly men also are at special risk of developing osteoporosis.

Do Most People Get Enough Calcium in What They Eat?

Because of concern that some people are consuming too little calcium, the U.S. Public Health Service has set a national health goal for people to eat food sources of calcium regularly. People from 12 to 25 years of age are encouraged to eat 3 or more servings a day of foods that are sources of calcium. This advice is appropriate for pregnant and lactating women because of their higher calcium needs. All adults 25 years and older are encouraged to consume 2 or more servings of calcium-rich foods daily.

How Do You Learn Which Foods Are Sources of Calcium

A good way to learn about food sources of calcium is to read nutrition labels. Most foods now have nutrition information on their labels.

The amount of calcium in a serving of food is listed on the nutrition label as a percentage of the Reference Daily Intake (RDI). The RDI for calcium is 900 milligrams (mg) for adults and children over 4 years of age. The RDI is not an amount recommended for you personally. It is a general reference number to help you determine how the amount of calcium in a serving of food relates to an average amount for a day.

More specific information for individuals comes from the National Academy of Sciences which recommends amounts of calcium for several age groups. For infants and children younger than 11 years, the recommended daily amounts range from 400 to 800 mg. The recommended daily amount of calcium for ages 11 through 24 years for both sexes, when maximum bone growth occurs, is 1,200 mg. The recommended daily amount for 25 years and older is 800 mg. For pregnant or lactating women, 1,200 mg of calcium a day is recommended. These recommended amounts can be reached easily by choosing foods each day that are good sources of calcium.

The richest sources of calcium are milk and other dairy products, which provide much of the calcium in U.S. diets. Some people cannot or only poorly digest the sugar (lactose) in milk, and are said to have "lactose intolerance." Most people with lactose intolerance, however, are able to consume small amounts of milk and other products containing lactose without distress. Also low-lactose and reduced-lactose dairy products are available.

Some foods containing relatively small amounts of calcium but that are eaten frequently during the day, for example, bread, are also good sources of calcium. Other nonfood sources, such as drinking water and some medications, such as antacids containing calcium carbonate, may also contribute to the level of calcium that you consume.

What Do Label Claims About Calcium Mean?

Besides the amount of calcium on the nutrition label, you may see claims about calcium in other places on the package of some products. There are two kinds of these label claims—content claims and health claims.

Content claims are those made about the *amount of calcium* the food contains. For example, a label may say "high in calcium" or "source of calcium." FDA allows a food that contains 20 percent or more of the RDI per serving to be labeled as a "high" in calcium, while a food containing from 10 percent to 20 percent of the RDI per serving can be labeled as a "source" of calcium.

Some foods that are high in or sources of calcium may contain one or more nutrients that increase the risk of a diet-related disease. For example, a high sodium intake is linked to high blood pressure in some people. To alert consumers, a claim about calcium content cannot be made on the label of such foods without indicating the presence of the other nutrient. A label might say, for example, "High in calcium; see nutrition label for information about sodium and other nutrients."

Health claims are those made about the relationship between calcium and osteoporosis. A health claim can be made only on foods that contain 20 percent or more of the RDI of calcium per serving and do not contain another nutrient (or nutrients) that increase the risk of a diet-related disease or health condition. Here are some examples of the kinds of foods on which you may see such claims: low fat milk, skim milk including dry skim milk, buttermilk made from skim milk, chocolate drinks and yogurt made from skim or low fat milk, reduced-calorie chocolate and cocoa dairy drink mixes, orange breakfast drinks, and tofu.

What About Dietary Supplements of Calcium?

The first important approach to getting enough calcium is to choose a healthful diet that has food sources of calcium. If for some reason (such as food intolerance or an increased calcium need during pregnancy or lactation), it's difficult to eat foods with enough calcium, a supplement to the diet may be appropriate. Supplements that exceed the recommended levels are unnecessary, however, and provide no further benefit to bone health. For further guidance, a personal physician or dietitian may be consulted.

Other Risk Factors for Osteoporosis

In addition to eating food sources of calcium regularly, improving some other habits may help to reduce the risk of osteoporosis. Regularly performing moderate weight-bearing exercise, such as walking, can help to increase bone mass during the bone-forming years. In addition, choosing not to smoke and limiting alcoholic beverages are healthful ways to reduce your chances of developing the disease.

Older people benefit from regular exercise that strengthens their muscles and helps lessen the danger of falls that may result in broken bones. A safe environment, such as removal of scatter

rugs, is also important for elderly people.

Facts to Keep in Mind

- It's the total combination of foods that you eat regularly—both the kinds and the amounts—that's important in terms of good nutrition. Eating a particular food or foods isn't a magic key that will assure that you have a more healthful diet.
- Eating a healthful diet, in itself, doesn't guarantee good health. However, a healthful diet is an important part of a healthy lifestyle that includes, for example, regular physical exercise, not smoking, not drinking alcoholic beverages in excess, and not abusing drugs.
- In addition to what you eat, many factors may be related to your own chance of developing a particular disease, for example, your heredity, your environment, and the health care that you get. Our knowledge about most diet-health relationships is incomplete and will improve as scientific knowledge increases. However, enough is known today about some of these relationships to encourage changes in dietary practices believed to be beneficial.

VII. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VIII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

IX. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

X. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of the Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.72 is added to subpart E to read as follows:

§ 101.72 Health claims: calcium and osteoporosis.

(a) *Relationship between calcium and osteoporosis.* An inadequate calcium intake contributes to low peak bone mass and has been identified as one numerous many risk factors in the development of osteoporosis. Peak bone mass is the total quantity of bone present at maturity that experts believe has the greatest bearing on whether or not a person will be at risk of developing osteoporosis and related bone fractures later in life. Another factor that influences total bone mass and susceptibility to osteoporosis is the rate of bone loss after skeletal maturity. An adequate intake of calcium is thought to exert a positive effect during adolescence and early adulthood in optimizing the amount of bone that is laid down. However, the upper limit of peak bone mass is genetically determined. The mechanism through which an adequate calcium intake and optimal peak bone mass are thought to reduce the risk of osteoporosis relates to the fact that all persons lose bone with age, hence those with higher bone mass at maturity take longer to reach the critically reduced mass at which bones can fracture easily. The rate of bone loss after skeletal maturity also influences the amount of bone present at old age and can influence an individual's risk of developing osteoporosis. Maintenance of an adequate intake of calcium later in life is thought to be important in reducing the rate of bone loss particularly in the elderly and in women during the first decade following menopause.

(b) *Significance of calcium.* Calcium intake is not the only recognized risk factor in the development of osteoporosis multifactorial bone disease. Other factors including a person's sex, race, hormonal status, family history, body stature, level of exercise, general diet, and specific life style choices such as smoking and excess alcohol consumption affect the risk of osteoporosis.

(1) Heredity and being female are two key factors identifying those individuals at risk for the development of osteoporosis. Hereditary factors include race, notably Caucasian and possibly Asians are characterized by lower peak bone mass at maturity, and have a significantly higher incidence of bone fracture with increasing age, than African Americans.

(2) Maintenance of an adequate intake of calcium throughout life is particularly important for a subpopulation of individuals at greatest risk of developing osteoporosis and for whom adequate dietary calcium intake may have the most important beneficial effects on bone health. This target subpopulation includes adolescent and young adult Caucasian and possibly Asian American women. In addition, those individuals with known family histories of osteoporosis are also at greater risk of developing this bone disease later in life.

(c) *Health claim conditions.* A food label or labeling may contain a health claim stating that consumption of an adequate calcium intake throughout life helps to optimize peak bone mass during adolescence and early adulthood and to slow the rate of bone loss later in life and, by maximizing the amount of bone present in later years through these mechanisms, may reduce the risk of osteoporosis and related bone fracture provided that the following conditions are met by the product:

(1) All requirements for health claims as defined in § 101.14 are met;

(2) A serving of food or a total daily recommended supplement intake meets or exceeds the requirements for a "high" level of calcium as described in § 101.54;

(3) The calcium content of the product is assimilable;

(4) Dietary supplements shall meet the United States Pharmacopeia standards for disintegration and dissolution; and

(5) A serving or total daily recommended supplement intake does not contain more phosphorus than calcium on a weight per weight basis.

(d) *Health claim requirements.* Health claims relating adequate calcium intake to the possible reduction in the risk of osteoporosis may be used on the label and in the labeling provided that such statements comply with the following requirements:

(1) The claim shall make clear that adequate calcium intake throughout life is not the only recognized risk factor in this multifactorial bone disease by listing the specific factors, including a persons's sex, race, age, and family history, that place them at risk of developing osteoporosis and stating that an adequate level of exercise and a well-balanced diet are also needed;

(2) The claim shall not convey the misconception that the risk of osteoporosis is equally applicable to the general United States population. The claim shall clearly identify the populations at particular risk for the development of osteoporosis. These include white (or the term "Caucasian") women and may include Asian women in their bone forming years (approximately 11 to 35 years of age or the phrase "during teen or early adult years" may be used). These may also include menopausal (or the term "middle-aged") women, persons with a family history of the disease, and elderly (or the term "older") men and women;

(3) The health claim shall state that adequate calcium intake throughout life is linked to reduced risk of osteoporosis through the mechanism of optimizing peak bone mass during adolescence and early adulthood. The phrase "build and maintain good bone health" may be used to convey the concept of optimizing peak bone mass. When reference is made to persons with a family history of the disease, menopausal women, and elderly men and women, the claim may also state that adequate calcium intake is linked to reduced risk of osteoporosis through the mechanism of slowing the rate of bone loss;

(4) The claim shall not quantitate the degree of reduced risk of osteoporosis that may result from maintaining an adequate calcium intake throughout life; and

(5) The health claim shall state that a total dietary intake greater than 200 percent of the recommended daily intake (1,800 milligrams (mg) of calcium) has no further known benefit to bone health.

Sample Health Claim

Osteoporosis affects older persons, especially middle-aged, white women and those whose families tend to have fragile bones in later years. A lifetime of regular exercise and eating a healthful diet that includes enough calcium, expecially during teen and early adult years, builds and maintains good bone health; and may reduce the risk of osteoporosis later in life. Adequate calcium intake is important, but intakes above about 1,800 mg are not likely to provide any additional benefit.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following table will not appear in the annual Code of Federal Regulations.

BILLING CODE 4160-01-M

TABLE 1

Calcium and Osteoporosis: Effects of Calcium on Bone Status

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Angus R. M., et al., 1988 (Ref. 18)	Cross-sectional study To determine influence of diet on bone mass in proximal femur, intake of 14 nutrients measured, and bone mineral density quantitated by dual photon absorptiometry (DPA) Bone mineral density also measured in spine and bone mineral content in forearm by single photon absorptiometry	159 White women, aged 23 to 75 years Volunteers, Australia Study Participants asked to record their food and fluid intake for 4 consecutive days by weighing all items on a portable digital scale	None	None	Mean calcium intakes for premenopausal and postmenopausal women were 759 and 717 mg/day, respectively	Usual dietary habits Mean calcium intake calculated from 4-day weighed food record	None	This was a study of multiple nutrients	No significant correlation was found between current calcium intake and bone mass at any site	Results suggested that bone mass is influenced by dietary factors other than calcium Appropriate use of multiple logistic regression
Baran, et al., 1990 (Ref. 25)	Randomized prospective clinical trial Measured: bone density of the lumbar spine by dual photon absorption Blood chemistries measured every 4 weeks included lipid profiles and parathyroid hormone	59 started (37 finished) women (30 to 42 years old premenopausal Control n = 22, Average increase in calcium intake = 610 mg/day	3 years (36 months)	Dairy foods	500 to 600 mg/day as dairy foods	3-day dietary histories repeated Instruction on calcium intake of dairy foods Compliance confirmed with 24-hour urine calcium measure Urged to use low fat dairy products Habitual calcium intake:? Control = 892 mg/day treatment = 962 mg/day increased to 1300 to 1500 mg/day	All groups were age and weight matched with no difference in habitual calcium intake or initial bone densities Direct questions and HDL-Cholesterol profiles showed no group differences in exercise patterns, thus it was no considered a confounder	None	No change in vertebral bone density over 3-year duration in women consuming the dairy supplemented diet, but the untreated controls showed a significant decline (-2.9%) that differed from the treated group at 30 and 36 months No changes in any parameter of lipid profile or calcium homeostasis other than a significant increase in urinary calcium excretion was observed in the treated group	Unlike earlier studies, this is the first to confirm calcium intakes Suggests that dietary modification via supplementation with dairy products during the period of consolidation could retard vertebral bone loss and decreased the incidence of osteoporosis A very important study, despite high attrition rate of 37%

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Cauley, J. A., et al., 1988 (Ref. 36)	Purpose: To examine the interactions between normal levels and calcium with cortical bone Researchers combined factors for the development of peak skeletal mass (milk consumption during childhood and adolescence) with factors that may be related to the maintenance (serum hormone levels and dietary intakes of calcium) of bone integrity after menopause Hormones studied: Estrone Testosterone Androstenedione Calcium intake in childhood, adolescence, and adulthood was assessed retrospectively from responses to questions concerning frequency of milk consumption at various stages of life	174 postmenopausal women (healthy) All participants were in a 3-year randomized clinical trial designed to evaluate of walking in postmenopausal bone loss	3 years	Habitual and life time calcium intake	None	Calcium intake by food frequency method: 25th percentile: 407 mg/day 50th percentile: 684 mg/day 75th percentile: 942 mg/day Mean daily calcium intake 768 mg/day	None of the participants was receiving estrogen therapy at baseline	Bone measures were assessed with a computed tomographic scanner in the dominant radius at a site three tenths of the distance from the wrist to the elbow approximately one month after the annual clinic visit Current calcium intake was estimated at year 1 and year 3 by a food frequency questionnaire in which women recorded the frequency of consumption of various foods known to be common sources of calcium At year 1, calcium intake was also assessed by 3-day food records that were documented by nutritionist and coded according to the USDA handbook	Little relationship found between androgen hormones and radial bone density Estrone levels were independently related to radial bone density Examination of the relationship of calcium intake to bone revealed a protective effect solely in women who reported high "lifetime" calcium intakes Considering calcium and estrone together revealed an additive relationship between the 2 factors, in that women with high estrone and high calcium levels had significantly greater bone density than women with less calcium and or estrone	Results suggest that a lifetime of adequate calcium intake coupled with adequate levels of serum estrogens could maximize bone density after menopause

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Dawson, Hughes, et al., 1990 (Ref. 44)	Intervention placebo: Controlled Double blind Randomized Measured: Bone mineral density of spine and femoral neck by DPA Biochemical markers of calcium homeostasis	301 healthy postmenopausal women Early postmenopausal n = 67 average = 54.5 years year pm = 3.2 Sub-Groups High Calcium, n = 124 Low Calcium, n = 112 Late postmenopausal n = 169 average = 59.9 years	24 months	Placebo micro crystalline cellulose calcium carbonate Calcium citratemalate (CCM) Depending on habitual calcium intake, women were randomized to 3 treatments Thus, 6 treatment groups total	500 mg/day 500 mg elemental calcium 500 mg elemental calcium all tablets	Assessed by questionnaire initially and every 6 months By design half selected had habitual calcium intakes of: (1) < 400 mg/day (2) 400 to 650 mg/day	None	Effectiveness of calcium supplementation was affected by years since menopause Therefore data analyzed separately for: (1) Menopause in last 5 or fewer years (accelerated rate of a bone loss) (2) Menopause more than 5 years ago Time of day of supplementing (before bedtime) may have produce different effects between calcium carbonate and CCM, since calcium carbonate is absorbed better when consumed with a meal	Women in early menopause lost bone from spine and this rapid rate of loss was not affected by calcium supplementation (500 mg calcium) from any source Women in late menopause, the rate of bone loss was less rapid in those with higher habitual calcium intakes and there were no differences in bone density among treatment groups at any site All late postmenopausal women had significant bone loss from the spine, except those with a lower habitual calcium intake who received CCM For those on a low dietary calcium diet, CCM significantly decreased the rate of bone mineral loss from the spine, femoral neck, and radius Calcium carbonate decreased bone loss only at femoral neck and radius.	Study presents strong evidence that bone loss in early postmenopausal is unresponsive to calcium supplementation Women in late menopause, whose habitual calcium intake is less than 400 mg may reduce their bone loss by increasing their calcium intake to 800 mg/day

Table 1 continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Desai, S., et al., 1987 (Ref. 48)	Cross-sectional Measured: Bone mineral density by DPA of the lumbar vertebrae Estimates of calcium intake made from 3-day diet histories via computer software package	60 normal premenopausal 30 to 40 years of age Average age = 35	None	Habitual calcium intake assessed from 3-day diet history Average = 868 mg/day Range: 278 to 2064 mg calcium/day	None	None	Subjects had no other factors known to alter calcium or bone metabolism	None	Bone density at any site did not correlate with calcium intake, age or calorie intake	Dietary data from a 3-day record is not sufficient estimate of habitual calcium intake No measurement of physical activity which may have been an important confounder in this age group
Fujita, T., et al., 1990 (Ref. 55)	Clinical trial: Non placebo Controlled Not blinded Not randomized Japanese study Measured: Radial bone mineral density by single photon absorptiometry and spinal trabecular bone density by quantitative computed tomography	12 test subjects Asian female > 70 year age, normal except for osteopenia expected for age 20 controls age matched All subjects in geriatric hospital All subjects in late menopause	24 months	Oyster shell electrolysate (OSE)	900 g of calcium as OSE	Hospital diet consumed by all subjects Contained about 600 mg/day calcium	No record control of physical activity	Differences in physical activity may have confounded the results It remains unclear	Radial bone mineral density increased significantly in subjects consuming the OSE calcium and decreased significantly in the untreated controls No change in spinal bone density in either calcium treated or untreated controls Concluded that in late menopause had positive response of cortical but not cancellous bone to calcium supplementation	Study flawed by large percentage of attrition attributed to their age (>70)

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Halioua, et al., 1989 (Ref. 60)	Cross-sectional Measured: bone mineral content and bone mineral density of the nondominant arm at the distal and mid (2/3) radius by single-photon absorptiometry	181 premenopausal women aged 20 to 50 mean age, 3 to 5 years All Caucasian	None	Habitual diet Calcium intakes for current, past, and lifetime classified as; Low, (L500 mg/day) Intermediate (>500 mg and <800 mg/day) High (>800 mg/day)	Diet assessment included current, past and lifetime calcium intake Used a quantitative food frequency questionnaire based on a 1 week intake Validated on a subset of 20 women on a 3-day dietary intake record (r = 0.52 Between the 3 methods) Similar quantitative food frequency questionnaire used to determine past and both current and past intakes were used to estimate lifetime calcium intake Appears to be a carefully conducted procedure conducted by a trained professional		Physical activity assessment, used a questionnaire to establish: Current activity Past activity Lifetime activity with each classified as: sedentary, moderate or active	All menopausal women, or women with abnormal menstrual cycle excluded	An intermediate or high lifetime calcium intake was associated with significantly higher bone mineral density and content at both distal and midradius when data was adjusted for physical activity Similar findings were observed when data was adjusted for calcium intake Thus, lifetime high calcium, and active level of exercise was associated with highest radial bone density	Any estimate of past or lifetime calcium intake is inherently weak, but effort was made to validate against current intake estimate Findings suggest that both adequate calcium intake and regular exercise during adolescence enhance peak bone mass

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Holbrook T., et al., 1988 (Ref. 72)	Prospective cohort	957 white upper middle class subjects, aged 50 to 79 years (416 men, 531 women) sub-sample of cohort of 6,155 including all hyperlipidem (a 15% random sample)	14 years	Dietary calcium usual intake estimated from 24-hour diet recall taken in 1973 to 1975 and quantified in 1985	Range of estimated calcium intake: not given	Use 24-hour recall, weak method for estimate of calcium intake	Alcohol, age, obesity, sex, smoking, exercise, estrogen replacement	None	Hip fractures were usually proportional to calcium intake in both sexes therefore positive effect associated with calcium 33 hip fractures (male 15 and female 18) mean calcium intake: mg/day Men with fracture = 305.9 Men without fracture = 384.9 Females with fracture = 319.8 Females without fracture = 401.3	Weakest point of study was method of estimating calcium intake from 24-hour recall, particularly since the data were collected 10 years prior to analysis Study was weakened by small sample size Unresolved issue as to whether calcium effect is preventive after 50 years of age or is the therapeutic end result of habitual higher calcium intake, thus affecting peak bone mass

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Kanders, B., et al., 1988 (Ref. 78)	Non randomized Cross-sectional Measured: Bone mineral mass by SPA 1/3 radius site Bone mineral density of the lumbar spine by DPA Physical activity measurement via Minnesota Leisure Time Activity Questionnaire Daily walking by a 7-day pedometer recording Nutritional assessment by 24-hour dietary recall with food models and a prospective 6-day record to yield a weighted 1-day intake All women were within 20% of ideal body weight	60 women eumenorrheic, healthy normal age 25 to 34 years old	None	Lifestyle variation with regard to habitual calcium intake	None	Mean calcium: 871 mg/day Range: 286 to 2,128 Only one subject avoided dairy products 17 were taking calcium supplement users for 3 years	Exercise monitored: Energy Expended: Average Kcal/day = 960 Range: 286 to 2,128 Examined statistically as: <970 kcal/day >970 kcal/day	None	Highly significant correlation between bone mineral density of the lumbar spine and overall level of physical activity Radial bone density showed no correlation to physical activity and only a modest relations to calcium intake which was statistically significant Statistical comparison made after the group was divided at the RDA for calcium of 800 mg/day both vertebral and radial mineral were significantly greater in those with high calcium intake The mean spinal bone mineral density was highly significantly different between women with the highest calcium intake and physical activity level, relative to those who were relatively inactive and on a lower calcium intake. -Bone mineral density of the spine did not increase with calcium intakes above 800 - 1000 mg/day, implying a calcium threshold effect.	General conclusion that Bone mineral density of the spine can be influenced by both mechanical stress of physical activity and optimal calcium nutrition during the period of skeletal maturation (consolidation) Data implied an optimal calcium intake between 800 to 1000 mg of calcium

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Kelly, P. J., et al., 1990 (Ref. 82)	Cross-sectional Measured: Bone mineral density of radius by single photon absorptiometry and lumbar spine and hip by DPA to assess relation between bone mineral density and: Dietary calcium intake Anthropometric features Age Serum sex hormone level	48 normal men (age 21 to 79, median 44)	None	Dietary calcium assessed from questionnaire validated against 4-day dietary record	Range: 0.3 to 1.7 g/day (from figure 1)	Not specified	None	None	Dietary calcium intake was significant predictor of bone mineral density of axial bones, explaining 24% and 42% of the variance at the lumbar spine and femoral neck, respectively This effect was independent of weight In contrast with the axial skeleton, bone mineral density at each forearm site was predicted by weight and an index of free testosterone but not dietary calcium intake	Strengths: Appropriate application of stepwise logistic regression Limitations: Specific diet of study participants not described Level of physical exertion not discussed, may present as confounder
Lacey, M., et al., 1991 (Ref. 86)	Cross-sectional Measured: Mid-radial bone mineral content and bone density by single photon densitometry	178 Japanese women living in Japan 89 premenopausal women (35 to 40 years) 89 postmenopausal women (55 to 60 years)	None	Habitual dietary intake	None	Habitual diet assessment carried out on 3-day food diary interpreted by American interviewer using Japanese computerized nutrient data base A quantitated food frequency questionnaire was used to assess calcium intake between 14 to 22 years of age	None	Physical activity Medical history and anthropometric measurements were taken to determine influence on bone status	Current calcium intake was not associated with bone indices on either pre- or postmenopausal women Vegetable intake and current milk intake were positively correlated with mid-radial indices An important finding since both are calcium rich foods	Assessment of past calcium intake in these very elderly ladies was confounded by probate food restrictions imposed during WWII when many of these women would have faced food restriction

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Lutz, J., et al., 1990 (Ref. 94)	Cross-sectional Measured: Bone mineral content of the lumbar spine and right proximal femur (femoral neck and trochanter) by dual-photon absorptiometry	37 with mother-daughter pairs aged 52 + 7 years and 25 + 4 years Mothers premenopausal n = 20 postmenopausal n = 17	None	3-day dietary intakes assessed dietary contribution notably calcium Mean calcium intakes: mother = 1102 mg/day daughters = 818 mg/day 13 mother had <800 mg/day 7 daughters had <800 mg/day	None	None	Supplemental calcium intake by mothers (n = 21) averaged 580 mg/day by daughters (n = 13) averaged 340 mg/day This may have confounded the study Another confounder may be the heterogeneity of the subjects with respect to their age and menopausal status Exclusion criteria in selecting pairs included estrogen use or other factors that would affect bone	23 mothers and 19 daughters were taking vitamin/mineral supplements	Total calcium intake was significantly correlated with 3 bone mineral density sites for the daughters, but not for the mothers	3-day dietary records are not sufficient to get an accurate estimate of calcium intake Study may be flawed by over interpretation of the findings concerning calcium intake The method used was not competent to estimate habitual calcium intake
Matkovic, et al., 1990 (Ref. 97)	Calcium intervention Longitudinal trial Measured: Calcium balance Radiogrammetry of the hand Single photon absorptiometry of distal radius DPA of the lumbar spine	30 adolescent females healthy 14 years old at onset eumenorrheic 18 of these participated in the balance study	2 year	Habitual dietary calcium or-- Supplemental calcium from either milk or calcium carbonate	Subjects stratified into 2 groups: Control n = 9 <850 mg calcium/day initially with a continued average intake of 750 mg calcium/day Calcium supplemented Milk group n = 10 <10,900 ml of milk/day Calcium carbonate group n = 12 took 4, 250 mg calcium tablets/day average calcium/day = 1640 mg Stratification was based on prestudy calcium intake	Determined from 3-day food record initially and at 6, 12, 18 and 24 weeks	None	For statistical analysis the high calcium groups were pooled since baseline values, bone mass, nutrition etc. were the same	While trend toward an increase in bone density in those girls consuming the higher calcium intake was observed over 2 years in the distal forearm and spine, this difference did not reach statistical significance Both groups showed a significant increase in bone mass and more significantly bone density Girls retained 200 to 500 mg calcium/day suggesting that inadequate calcium intake may translate into inadequate retention and a reduction in peak bone mass	No adjustment was made for physical activity differences between the two groups which may have a confounding effect Very difficult study design to follow--too convoluted Due to the small "n" in this study of 9 for the control and 20 for the calcium supplement group a type II error is possible

Table 1--continued

Mazess, R., et al., 1991 (Ref. 98)	Longitudinal observation over a 2-year period Dual-photon absorptiometry of lumbar spine and Single-photon absorptiometry of the standard one-third radius and distal radius sites	200 to 300 White premenopausal women aged 20 to 39 All were ambulatory and free of current or previous chronic disease or medications known to affect bone	2 years	Normal diet, content assessed from several; 24-hour reporting periods over the two years using precoded Nutrient Adequacy Reporting System	Dietary calcium intake 909 + 351 mg/day	Normal diet	No specific treatments	Study of effects of age, dietary intake, physical activity, smoking and birth-control pills on bone mineral density	There was no association of calcium intake with bone mineral density or changes in bone mineral density Current calcium intake was not a significant influence on bone and mineral density in this age group No apparent additive interaction of activity and calcium intake on bone mineral density Body weight was a better predictor of bone mineral density than was any other factor No association of bone mineral density or bone mineral density changes with calcium	Appropriate analysis of data using linear and multiple regression Calcium intake and methods were weak, used less reliable method of 24-hour recall

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
McCulloch R., et al., 1990 (Ref. 99)	Cross-sectional Random selection Measured: Cancellous bone density of the os calcis using computed tomography	101 healthy normal females 20 to 35 years old	None	Childhood milk consumption Current dietary calcium intake Avocational Physical activity Various Lifestyle variables, e.g., smoking Range of Current Calcium Intake: 150 to 1560 mg/day	None	Dietary information determined from a questionnaire as was assessment of childhood physical activity Questionnaire was readministered 10 weeks later and discrepancies resolved Current levels of physical activity and calcium intake also evaluated by a 2-week and 1-week recall check test Limited explanation given for this check test	Exclusion criteria included: menstrual disfunction, kidney disease, etc.	None	There was a nonsignificant correlation between calcium intake and bone density of the os calcis There was no significant difference in bone density of the os calcis of subjects grouped according to self classifications high, moderate or low childhood milk consumers	Questionable competency of the dietary calcium intake validation estimate--not offered Diet and calcium intake analysis, a very weak point of this study

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Nelson, M., et al., 1991 (Ref. 102)	Prospective clinical trial, Double-blind, placebo controlled, Randomized for dietary, variable, Assigned according to preference to exercise training or sedentary Measured: Trabecular bone density of Lumbar spine (L1-L3) by computed tomography (QCT) Femoral-neck (nondominant) and Lumbar spine (L2-L4) bone mineral density by DPA Bone mineral density of the shaft of the nondominant radius (1/3 distance) by single photon absorptiometry Total body calcium by delayed gamma neutron-activation Various measurements of muscle strength, aerobic capacity and body fluid analysis for hormones electrolytes.	36 postmenopausal Caucasian women All > 2 y postmenopause Average = 10.8 year Average age = 60.2 All < 130% ideal body weight	12 months	Milk with high calcium content 831 mg calcium/day Moderate calcium milk drink-placebo artificial milk 41 mg calcium/day	None	Usual diet, instructed all subjects to consume 800 mg calcium/day through inclusion of 4 servings of dairy products per day	Exercise which included walking 1 mile per day 4 times/week for 52 weeks or Sedentary no scheduled routine exercise but were allowed weekend recreation 4 Groups designated as: Exercise, moderate dietary calcium n = 9 Sedentary, moderate dietary calcium n = 9 Sedentary, high dietary calcium n = 9	Possible differences in dietary content of Vitamin D, protein and phosphorus Groups differed initially only by parity: Exercise group = 4.3 Sedentary = 2.4.	Bone mineral density of the spine, measured by QAT decreased 7% in sedentary group and increased in exercise group by 0.5% (p = 0.028) but calcium intake had no significant effect Femoral neck bone mineral density measured by DPA decreased 1.1% in moderate calcium group and increased 2% in high calcium group (p = 0.014) and no significant effect of exercise No change in hormone or urinary metabolism observed with any treatment	Well controlled and well designed study examining more than usual endpoints Important finding was that due to varying proportion and rates of bone turnover of cancellous and cortical bone at various skeletal sites, exercise and dietary calcium may preferentially modify bone mineral at these different sites Findings confirm previous studies showing calcium to effect cortical bone but not cancellous bone Limit power of study since each group contained only 9 subjects

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Picard, D., et al., 1988 (Ref. 111)	Cross-sectional Observational Measured: Bone mineral content of the spine by DPA and of the forearm by single photon absorptiometry	183 women, aged 40 to 50 average age = 43.8 years all normal healthy with regular menses	None	Range of historical intake: High > 1000 mg/day n = 38 Medium 500 to 1000 mg/day n = 75 Low < 500 mg/day n = 70	Historic and habitual calcium intake: Average calcium intake at age 20 = 576 mg/day	Diet history taken to determine intake at age 20 3-day food recall to verify calcium intake	Estimates of caffeine, alcohol intake, cigarette smoking, exercise, estrogen use, and parity were also made	Homogeneous population of French Canadian women, geographic and racial differences were minimized	Significant positive correlations were noted between the bone mass measurement at the spine and forearm and weight, height and calcium intake at age 20 Significant differences were observed between the low and high calcium intake groups for the mean adjusted bone mineral content at both sites Concluded: Chronic calcium intake has a significant effect on lumbar bone mass indices in premenopausal women	Study did not indicate whether the effect of calcium intake was on the formation of maximal peak bone mass or on slowing the rate of bone loss at midlife Has all the predicted limitations inherent to a cross-sectional study examining historical dietary intake

Table 1--continued

Reference (author, date)	Study Design	Number and Description of Subjects	Duration of Study	Source and Identity of Test Material	Dosage of Test Material Used	Base Diet	Additional Treatments	Other Factors Affecting Interpretation of Data	Results	Comments
Polley, K. J., et al., 1987 (Ref 113)	Prospective intervention with consecutive and concurrent controls Random assignment to treatment Measured forearm mineral content by single photon absorptiometry	Postmenopausal women <65 years old 3 treatment groups 210 completed 52 strict controls, 122 not able to take supplements, 136 treated	Initial 9-month control period 9-months of the treatment (total duration 18 months)	Group 1: Reduced sodium Group 2: Increased dairy foods 1250 mg/day Group 3: diet + 1000 mg calcium as sandolcal total diet content: 1700 mg Untreated controls None	Group 1: None Group 2: 450 mg calcium, dairy Group 3: 1000 mg effervescent tablets of calcium gluconate, lactate and carbonate Untreated controls None	Group 1: 709 mg calcium Group 2: 711 mg calcium Group 3: 714 mg calcium Average for treated 711 mg calcium Untreated controls 717 mg calcium	Group 2: Subdivided into dairy products + salt restriction Dairy products only	Diet Sodium Content Group 1: 1827 mg/day Group 2: Restricted 1803 mg/day 2103 Group 3: (+ calcium) 2422 mg/day	Bone mineral content No significant differences in forearm mineral content for any treatment or subgroup, initially Rate of Bone Loss The difference between pretreatment and after 9-months of calcium was significantly reduced Calcium treated women had a greater reduction in the rate of bone loss, but it was not statistically different from the untreated strict controls Comparison of women within 10 year of menopause showed a significantly different (reduced) rate of bone loss in both the calcium supplement and dairy product only group, relative to untreated control.	Poor or questionable compliance, especially in control group Confusing design with too many variables Unexplained significant reduction in rate of bone loss in strict controls between period 1 and 2 Questionable inclusion of noncompliant subjects in control groups

Table 1--continued

Stevenson J. C., et al., 1989 (Ref. 125)	Cross-sectional study of bone density measurements of vertebral and proximal femur using DPA Possible predictors and risk factors for bone density were assessed in study participants	284 White healthy women-volunteers ages 21 to 68 Included 112 premenopausal women	Cross-sectional study	Dietary calcium intake assessed	Dietary calcium estimated mean calcium intake for premenopausal women was 598 g/day, while for postmenopausal women it was 619 g/day	An estimate of dietary calcium intake was derived form the current consumption of diary products	None	None of study participants was taking any drugs known to influence bone or calcium metabolism	Peak adult bone density had been attained soon after the end of linear skeletal growth Thereafter, there was some decline with age in the proximal, femur, but the major fall in bone density in all sites was related to the menopause Other factors decreasing bone density, and thus increasing risk for osteoporosis (low body weight, alcohol and cigarette consumption, nulliparity, lack of previous use of oral contraceptives, and lack of regular exercise) seemed to be important None, however could predict satisfactorily women at future risk for osteoporosis.	Values obtained for bone density were similar to those obtained from equivalent studies performed in women in the United States In agreement with others, no evidence obtained of skeletal consolidation in the third or fourth decade Weak assessment of dietary calcium intake; no validation

[Docket No. 91N-0096]

RIN 0905-AB67

Food Labeling: Health Claims and Label Statements; Lipids and Cardiovascular Disease

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to authorize the use on foods and food labeling of health claims relating to the association between reduction in dietary intake of lipids (particularly saturated fats and cholesterol), decreased blood cholesterol, and decreased risk of cardiovascular disease, particularly coronary heart disease. The agency reviewed this topic under provisions of the Nutrition Labeling and Education Act of 1990. The agency's conclusion is based on its review of the available scientific literature and on its review of conclusions and recommendations provided by the Federal government and other documents from recognized scientific bodies. The agency concludes that the strength and consistency of the extensive publicly available scientific evidence supports such claims, and that there is significant scientific agreement, among experts qualified by scientific training and experience, to evaluate such claims, about such support.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Paddy Wiesenfeld, Center for Food Safety and Applied Nutrition (HFF-268), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-245-1492.

SUPPLEMENTARY INFORMATION:

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the Nutrition Labeling and Education Act of 1990 (Pub. L. 101-535) (the 1990 amendments), which amended the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary) to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this issue of the **Federal Register** is a proposed rulemaking to establish general requirements pertaining to the use on food labels and in labeling of health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs, or other nutritional substances (referred to generally as "substances"), to a disease or health-related condition (proposed in "General Principles for Health Claims"). In the proposal on general requirements for health claims, FDA, following the provisions of the 1990 amendments, has tentatively determined that for foods that qualify for claims, such claims would only be justified for substances in dietary supplements as well as in conventional foods if the agency determines based on the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (section 3(b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x) that within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act, and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including lipids and cardiovascular disease, meet the requirements of the act. In this document, the agency will consider whether a claim on food or food products, including conventional foods and dietary supplements, on the relationship between lipids and cardiovascular disease would be justified under the standard proposed in "Food Labeling: General Requirements for Health Claims for Food."

B. Public Health Aspects: Basis for Considering a Health Claim Relating Lipids and Cardiovascular Disease

1. Cardiovascular Disease

The specific disease or health related condition identified in the 1990 amendments is cardiovascular disease, diseases of the heart and blood vessels. Cardiovascular disease is a major public health problem in the United States. Coronary heart disease (CHD) is the most common, most frequently reported, and most serious form of cardiovascular disease. Despite the dramatic decline over the past 15 years in the death rate from cardiovascular disease: 35 percent for all cardiovascular disease, 40 percent for CHD, and more than 50 percent for stroke (Ref. 36), CHD and stroke kill nearly as many Americans as all other diseases combined. Cardiovascular disease, primarily CHD, is also among the leading causes of disability. Changes in lifestyles, risk factor reduction, and medical intervention were major contributors to this decline (Ref. 36).

In order to be consistent with the magnitude of the public health problem and with the conclusions of the Federal government and other reports from recognized scientific bodies, such as the National Research Council (Ref. 20) and the Life Sciences Research Office (LSRO) (Ref. 78), the focus of this document is CHD rather than the broader problem of cardiovascular disease. CHD is the most common, most serious, and earliest form of cardiovascular disease, frequently producing symptoms and health problems in middle-aged adults (Ref. 20). Despite a declining death rate from CHD since the mid 1960's, CHD still accounts for more deaths than any other disease or group of diseases (Ref. 35). More than 1.25 million heart attacks occur each year (two-thirds occur in men), and more than 500,000 people die as a result (Ref. 35). In the United States, it is very common for significant pathogenesis of CHD to occur without easily detectable symptoms (Refs. 31 through 34). Thus, the total affected population is considerably larger than the statistics on death and illness would indicate. In addition to its impact on the nation's health, CHD costs the U.S. economy over $50 billion annually (Ref. 35).

2. Dietary Lipids

Food sources of dietary lipids commonly consumed in the United States include fats and oils (e.g., butter, margarine, vegetable oils, and shortenings), salad dressings, meats, and whole dairy products and egg yolk.

Digestion of food fats liberates fatty acids and other lipid components, including cholesterol, that are then absorbed for use in the body.

Fatty acids may be classified by length: short-chain (less than 6 carbons), medium-chain (6 to 10 carbons), or long-chain (12 or more carbons). Fatty acids may also be classified as saturated fatty acids (lacking double bonds), as monounsaturated fatty acids (containing one double bond), or as polyunsaturated fatty acids (containing two or more double bonds). The polyunsaturated fatty acids are subdivided into those whose first double bond occurs either three carbon atoms from the methyl end (omega-6-fatty acids) or six carbon atoms from the methyl end (omega-3-fatty acids) of the molecule. Dietary lipids and fatty acids are commonly referred to as "fat," e.g., as "total dietary fat" and as "saturated fat or saturated fatty acid" or "polyunsaturated fat or polyunsaturated fatty acid."

Dietary fats serve several major physiological functions. Small amounts (1 to 2 percent of total calories) of linoleic and linoleic acids, two polyunsaturated fatty acids, are essential in the diet as precursors of other essential lipids. Fats facilitate the intestinal absorption of fat-soluble vitamins. Cholesterol and other lipids are major components of all cell membranes. In addition, cholesterol is the precursor for synthesis of steroid hormones and bile acids.

Fat is the most concentrated source of dietary energy of all the nutrients, supplying 9 calories per gram (g) as compared to 4 calories per g from either carbohydrate or protein. More than one-third of the calories consumed by most people in the United States are provided by fat. In 1985, the estimated average intake of total fat ranged from 34 percent of caloric intake for children 1 to 5 years of age to 37 percent of calories for adults 19 to 50 years of age (Ref. 107). On average, saturated fat intakes were between 13 to 14 percent of calories. The major dietary sources of both total and saturated fats were dairy and meat products and baked goods.

Dietary cholesterol is also a type of dietary lipid, but it has different chemical and physiological properties from fatty acids. Cholesterol is derived either from the diet or from synthesis in the body. Only about 40 percent of ingested cholesterol is absorbed, the remaining 60 percent passes out in the stool. Average daily intakes of dietary cholesterol in the United States are estimated to be 304 milligrams (mg) and 435 mg for women and men, respectively (Refs. 20 and 33).

3. Relationship of Dietary Lipid (Saturated Fats and Cholesterol) and CHD

Because of the importance of CHD as a public health problem, identification of "modifiable" risk factors has received considerable research and public health policy attention since the early part of this century. Fatty streaks and cholesterol were identified many years ago as prominent components of the blood vessel (arterial) lesions whose buildup caused a narrowing or blockage of the blood flow to the heart (Refs. 20, 33, and 35). Following these early observations, a large body of scientific evidence has accumulated on the relationship of different types and amounts of dietary fats to risk of CHD. Based on the weight of the scientific evidence now available, virtually all recent dietary guidelines for Americans, whether from the Federal government or from the community of health professionals, have noted the high intake of dietary fat by the U.S. population and also the strong association of diets high in fat, particularly saturated fat and cholesterol, with increased risk of CHD (Refs. 20, 29, 31, 32, 33, 34, 35, and 36).

Many risk factors contribute to development of CHD. There is general agreement that elevated blood cholesterol levels are one of the major "modifiable" risk factors in the development of CHD (Refs. 31, 32, 35, and 36). Federal government and other reviews (Refs. 20, 31, and 33 through 36) concluded that there is substantial epidemiologic and clinical evidence that high blood levels of total cholesterol and low density lipoprotein cholesterol (LDL-cholesterol; LDL–C) are a cause of atherosclerosis (inadequate circulation of blood to the heart due to narrowing of the arteries), and represent major contributors to CHD (Refs. 20, and 31 through 36). Factors that decrease total blood cholesterol and LDL-cholesterol will also decrease the risk of CHD. High intakes of saturated fat, and to a lesser degree, of dietary cholesterol are consistently associated with elevated blood cholesterol levels. Thus, it is generally accepted that blood total and LDL-cholesterol levels are major risk factors for CHD, and that dietary factors affecting blood cholesterol levels affect the risk of CHD (Refs. 20, 31, and 33 through 35).

FDA has limited this review to those aspects of the dietary lipid and cardiovascular disease relationship for which the strongest scientific evidence and agreement already exists. This limitation was necessary because of the extremely large volume of literature available on the broader topic. Even with the narrow focus on dietary intakes of saturated fat and cholesterol, blood cholesterol levels, and risk of CHD, the volume of available scientific literature was large. Moreover, the focus that FDA has chosen is most consistent with current dietary guidelines for the U.S. population.

C. Regulatory History

1. Fat, Fatty Acids, and Cholesterol Labeling

The regulatory history of nutrient content and descriptive labeling for fat and related lipids reflects the changing nature of the scientific evidence over the years and also the increasing acceptance of research results by the general scientific community. Early emphasis was on dietary cholesterol. Later, as more research results became available, saturated fats were recognized as the primary dietary factor related to elevated blood cholesterol and to risk of CHD. At one time, it was felt that dietary modifications should be undertaken only under a physician's care. More recently, dietary recommendations for the general population have become the norm.

A detailed history of FDA policies on labeling of fat, fatty acids, and cholesterol is provided elsewhere in this issue of the **Federal Register** in the document on the use of nutrient content claims for these nutrients. Because of the availability of that history, FDA believes that it is not necessary to repeat it in detail here.

2. Health Claims

For many years, FDA has permitted firms to label foods with truthful, nonmisleading information about nutrient content. In the past, however, the agency did not permit firms to provide consumers with information in the label or labeling concerning how the food may be used to affect a disease or health-related condition because such claims could make the food a drug. A complete description of FDA's regulatory history in the area of health messages (subsequently, in this proposal, the term "health claim" is used in place of "health message" for consistency with terminology used in the 1990 amendments) is published elsewhere in this issue of the **Federal Register**, § 101.14. A brief summary is presented here.

In the **Federal Register** of March 14, 1973 (38 FR 6951), FDA promulgated regulations that provided, in part, that a food shall be deemed to be misbranded if its labeling represents, suggests, or

implies that the food, because of the presence or absence of certain dietary properties, is adequate or effective in the prevention, cure, mitigation, or treatment of any disease or symptom (see current 21 CFR 101.9(i) (1)).

In the **Federal Register** of August 4, 1987 (52 FR 28843), FDA proposed to change its policy to permit the appropriate use on food labeling of health claims. That document proposed to amend nutrition labeling regulations in § 101.9 to permit health claims when (1) they are truthful and not misleading; (2) they are supported by valid, reliable, and publicly available scientific evidence derived from well-designed and conducted studies consistent with generally accepted scientific procedures and principles performed and evaluated by persons qualified by expertise and training in the appropriate disciplines; (3) they are consistent with generally recognized medical and nutritional principles for a sound total dietary pattern; and (4) the food bears nutrition information in accordance with the requirements of § 101.9. There were wide differences in opinion and numerous adverse comments were received in response to the proposal.

In the **Federal Register** of August 8, 1989 (54 FR 32610), FDA published a request for comments on a wide range of food labeling issues, including health claims. On December 7, 1989, FDA convened a public hearing in Seattle. The topic of health claims was the prime focus.

Based on comments received, FDA withdrew the August 1987 proposal and published a reproposal in the **Federal Register** of February 13, 1990 (55 FR 5176). The 1990 reproposal proposed to more narrowly define appropriate health claims. As part of this reproposal, the agency stated that six topic areas would be evaluated for their appropriateness for health claims including lipids and cardiovascular disease.

D. Evidence Considered in Reaching the Decision

The agency has reviewed all relevant scientific evidence on saturated fat and cholesterol and their relationships to blood cholesterol levels (specifically total cholesterol and LDL-cholesterol) and risk of CHD. The scientific evidence reviewed included all conclusions reached in: "The Surgeon General's Report on Nutrition and Health" (Ref. 35); "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 29); "The Lipid Research Clinics Population Studies Data Book," Volume II, "The Prevalence Study—Nutrient Intake," (Ref. 149); "Population Strategies for Blood Cholesterol Reduction" (Ref. 33); "High Blood Cholesterol in Adults, Detection, Evaluation, and Treatment" (Ref. 31); "Hypertension and High Blood Cholesterol, Working Report on Management of Patients With" (Ref. 32); "The Relationship Between Dietary Cholesterol and Blood Cholesterol and Human Health and Nutrition" (Ref. 150); "Nutrition Monitoring in the United States, an Update Report on Nutrition Monitoring" (Ref. 30); and "Healthy People 2000: National Health Promotion and Disease Prevention Objectives" (Ref. 36).

The agency also considered the reports of recognized non-U.S. Government scientific bodies that bear on this topic. FDA reviewed the National Research Council's (NRC's) "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 20); "Recommended Dietary Allowances" (Ref. 136); "Lipids and Cardiovascular Disease" (Ref. 78); and "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 151).

To ensure that its review of the scientific evidence was complete, in the **Federal Register** of March 28, 1991, FDA published a notice (56 FR 12932) requesting scientific data and information relevant to the 10 specific topic areas identified in section 3(b)(1)(A) of the 1990 amendments, including dietary lipids and cardiovascular disease.

The agency reviewed and considered all comments submitted in response to the **Federal Register** notice in developing this document. Furthermore, the agency updated the conclusions reached in these documents by reviewing all human studies that have appeared in the literature since the publication of the documents listed above and all review articles. The agency also considered the results of nonhuman primate studies to the extent that they clarified human studies or suggested possible mechanisms of action.

E. Comments Received in Response to FDA Request for Scientific Data and Information

In response, to the FDA's request (56 FR 12932), FDA received 23 comments from food manufacturers, nutrient or dietary supplement manufacturers, national organizations of nutritionists and public health professionals, trade associations of nutrient supplement manufacturers, private physicians and health foundations, faculty of medical schools, and the Government of Canada. The comments dealt with the issue of lipids and cardiovascular disease as well as with the provisions and requirements of the 1990 amendments in general. FDA reviewed all of the documents, including books, abstracts, review articles, and scientific articles that were submitted. When appropriate, FDA included data submitted in scientific articles or books in its scientific literature review.

The majority of the comments, with one exception, expressed the view that the link between dietary fat and cholesterol intake and risk for cardiovascular disease was very strong. Many comments raised issues concerning the safety of polyunsaturated fatty acids in foods and supplements. Comments suggested that safety issues related to polyunsaturated fatty acids included increased risk of cancer and coronary thrombosis in humans, effects on immune function, and a role in osteoporosis. Comments recommended that consumption of foods (i.e., those high in salt) that alter other risk factors for CHD (i.e., hypertension) be included in the risk factor assessment of CHD.

The Director General, Food Directorate, Health and Welfare, of Canada submitted information on the regulatory status of health claims in that country which it considered helpful in the context of increased harmonization of regulations or standards affecting trade in specific products. Canadian law prohibits health claims on labels or in advertising when a nutrient is described for treatment, prevention, or cure of 46 diseases and disorders, including heart disease. On the relationship of the nutrient to the disease, the Canadian document stated:

> * * * the evidence linking saturated fatty acid intake with elevated blood cholesterol and the risk of heart disease is among the most persuasive of all diet-disease relationships. * * * Dietary cholesterol, though not as influential in affecting levels of blood cholesterol, is not without importance.

The Director General also stated that food label health claims regarding the role of fats in CHD risk would likely result in a food product being classified as a drug because the Food and Drug Act in Canada prohibits the advertising and sale to the general public of a food that is represented either by label or in advertising as a treatment, preventative, or cure for some 46 diseases, disorders, or abnormal physical states. Heart disease is among the major diseases for which such claims are prohibited.

Comments from national organizations of nutritionists and public health professionals advised that the agency should take a cautious approach to the use of health claims on foods and supplements with particular attention to avenues by which such claims might be abused or misinterpreted by the general

public. The comments recommended that scientific agreement should be the cornerstone for the use of health claims and that FDA should consider the data submitted in the context of meeting dietary requirements through intake of food. The comments asserted that only about 25 percent of the population may be responsive to reduction in dietary cholesterol and saturated fat, and thus the majority of the population at risk of cardiovascular disease may require medical advice and guidance and may need medication or a combination of medication and diet to achieve satisfactory lowering of serum cholesterol.

One comment recommended use of a formula that would indicate the cholesterol and saturated fat concentration in food. The term "cholesterol-saturated fat index" (CSI) was suggested. A low CSI index would indicate a low saturated fatty acid and cholesterol content. The use of such an index in planning low fat diets or in identifying potentially atherogenic foods was suggested. Comments from food manufacturers identified a number of modifiable risk factors for cardiovascular disease including dietary intake of saturated fat and cholesterol, sodium, fiber, and antioxidant vitamins. The manufacturers noted that both lifestyle and diet can have significant impacts on the risk of cardiovascular disease. One manufacturer submitted model health claims and examples of labeling. Another manufacturer suggested that the agency identify threshold levels of fats (saturated fatty acids, monounsaturated fatty acids, polyunsaturated fatty acids, total fat), and threshold levels of other dietary nutrients in relationship to fats. The comments expressed concern that deficiencies might be produced by significantly decreased fat intake. A manufacturer noted that a low fat food should contain the usual levels of all other important nutrients commonly found in that food. A manufacturer commented that low fat foods containing high concentrations of salt and sugar may lead to increased risk of cardiovascular disease by increasing hypertension and obesity, respectively.

One manufacturer expressed concern about varying nutrient densities of foods and how best to express nutrient content of foods. One food manufacturer suggested a need for further research in the area of trans fatty acids and serum cholesterol levels.

An association of medical professionals provided a number of references that suggest serum cholesterol goals for patients with noninsulin-dependent diabetes mellitus and patients with hyperlipidemia.

Trade organizations of supplement manufacturers provided a number of comments on the value and safety of dietary supplements and suggested categories under which health claims on dietary supplements might be classified. Comments also expressed concern about the amount of saturated fatty acids and total fat contained in the 2,350 calories per day reference diet proposed by FDA as the basis for nutrition labeling for the general food supply. The comments stated that this level of calories may represent excess calories, saturated fat, and total fat for a significant proportion of the population (i.e., women).

Comments from professional medical associations and members of university medical faculties suggested that the emphasis of health claims regarding fat and cardiovascular disease should be on reduction of both saturated fatty acids and total fat, and that complex carbohydrates are recommended as the major replacement for calories from fat.

Comments were submitted regarding definitions for saturated fatty acids and polyunsaturated fatty acids. One comment suggested that saturated fatty acids be subdivided in a manner analogous to the subdivision of omega-3 and omega-6 polyunsaturated fatty acids. The comment noted that fatty acids of less than 12 carbons in length (for example, lauric acid) are metabolized by the liver, while saturated fatty acids of more than 12 carbons in length are metabolized through the lymphatic system.

One comment dealt with the Keys equation (Ref. 20) and noted that the equation does not have a term for the amount of monounsaturated fatty acids.

As appropriate, comments will be responded to in this document in the review of the scientific literature or in the discussion of the proposed regulation.

II. Review of the Scientific Evidence

A. Federal Government Documents

In 1982, a monograph derived from the population studies of the Lipid Research Clinics Program (Ref. 149) provided extensive information on the prevalence of hyperlipidemia (elevated blood lipids) in the United States. The data from 17 Lipid Research Clinics throughout the United States were derived from a series of epidemiologic surveys aimed at identifying the distribution, causes, and consequences of hyperlipoproteinemia (elevated levels of lipid transport particles in the blood).

A report to Congress pursuant to the Food Security Act of 1985 (Ref. 150) prepared by the Department of Health and Human Services and U.S. Department of Agriculture (DHHS/USDA) concluded that carefully controlled studies under metabolic ward conditions leave little doubt that increasing dietary cholesterol will induce a rise in plasma total cholesterol in most people. The report stated that when all data are taken together, the increase in plasma cholesterol resulting from ingestion of dietary cholesterol averages about 10 mg cholesterol per 100 milliliters (decaliters (dL)) for every 100 mg dietary cholesterol per 1,000 calories consumed. Thus, the report stated, increasing dietary cholesterol from 300 to 500 mg per day for a person consuming 2,000 calories per day will cause an increase in the plasma cholesterol of about 10 mg per dL. The report found that the major effect of dietary cholesterol is to raise the LDL-cholesterol fraction of total blood cholesterol.

Comprehensive reviews of the relationship of dietary fats and CHD are included in recent Federal government reports. In 1988, the "Surgeon General's Report on Nutrition and Health" (Ref. 35) reviewed studies of associations between dietary factors and risk of chronic disease. The Surgeon General's report found that results of epidemiologic, clinical, and animal studies provided strong and consistent evidence for a relationship between high intakes of saturated fat, high blood cholesterol, and increased risk of CHD. Conversely, reductions in blood cholesterol levels reduce the risk of death from CHD. The report noted that excessive dietary saturated fat is the major contributor to total blood cholesterol levels. The report also noted: (1) The effect of dietary cholesterol on blood cholesterol levels is less consistent than that for saturated fats (Ref. 35); (2) the roles of other dietary fats such as monounsaturated fatty acids and polyunsaturated fatty acids were not well defined. The Surgeon General's report concluded that the disproportionate consumption of foods high in fats was of primary concern for Americans. The Surgeon General's report recommended reduction in intake of fats (especially saturated fats and cholesterol). Although the relationship of CHD and lipids was primarily attributable to saturated fats and cholesterol, the recommendation for changes in American dietary patterns included a reduction in consumption of total fat because of the possible association of total fat with risk of other

diseases (cancer and diabetes), because of the likely role of high dietary fat intakes in increased risk of obesity (another risk factor for CHD), and because a decrease in total fat consumption facilitates a reduction in saturated fatty acids.

DHHS and USDA in "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 29) state that the lipids in American diets most often and most strongly associated with increased risk of atherosclerotic CHD are saturated fat and cholesterol. CHD rates and population risk were most strongly related to average serum cholesterol levels, particularly LDL-cholesterol levels. According to this report, other factors strongly linked with increased risk of CHD are high blood pressure, smoking, and diabetes. The relationship between obesity and CHD risk was more variable. Among the recommendations from the DHHS/USDA report to Congress relating to decreasing the risk of CHD include: decreasing the total amount of fat in the diet to less than 30 percent of calories; decreasing the amount of saturated fat in the diet to less than 10 percent of calories; eating less animal fat (the source of all dietary cholesterol) to aid in reducing serum cholesterol; and restricting intake of salt to aid in decreasing blood pressure (Ref. 150).

Reports from the National Cholesterol Education Program (NCEP); National Heart, Lung, and Blood Institute, National Institutes of Health, 1988 to 1990) reached similar conclusions regarding relationships among intake of dietary saturated fats and cholesterol, elevated blood cholesterol levels, and CHD (Refs. 31 through 34). The reports noted that approximately 55 percent of adult Americans have cholesterol levels at or above a desirable level. The reports also emphasize the important roles of genetic and environmental factors in blood cholesterol levels. The reports concluded that excessive intake of saturated fat, total fat and dietary cholesterol, together with excessive body weight, all contribute to elevated blood cholesterol levels. The reports stated that the role of total fat intake is not direct, but reduced fat intake aids in decreasing intakes of saturated fat and cholesterol and may facilitate maintenance of ideal healthy body weight. The National Cholesterol Education Program (NCEP) (Refs. 31, 33, and 34) recommended the following pattern of nutrient intake for healthy Americans:

(1) Consume less than 10 percent of total calories from saturated fatty acids;

(2) Consume an average 30 percent of total calories or less from all fat;

(3) Consume dietary energy in amounts needed to reach or maintain a desirable body weight; and

(4) Consume less than 300 mg of cholesterol per day.

The NCEP panel, noted compelling evidence that the atherosclerotic process (and hypertension) begins in childhood and progresses into adulthood. Toddlers over 2 years of age may safely make the transition to recommended eating patterns as they begin to eat with the family (Ref. 34). The NCEP recommendations are not intended for infants from birth to 2 years of age (Ref. 34).

The Public Health Services (PHS) DHHS report "Healthy People 2000: National Health Promotion and Disease Prevention Objectives," (Ref. 36) noted that cardiovascular disease, primarily CHD and stroke, kill nearly as many Americans as all other diseases combined, and that a casual relationship between high blood cholesterol and CHD has been demonstrated (Ref. 36). As noted in other Federal government documents, the report stated that the key modifiable factors that influence risk of CHD include: cigarette smoking, high blood cholesterol, high blood pressure, excessive body weight, and sedentary lifestyle. Reducing death from heart disease and stroke, and reducing mean serum cholesterol level among adults to no more than 200 mg per dL, are among the major public health goals identified in the Healthy People 2000, report. The Healthy People 2000 report recommended that Americans should reduce dietary fat intake to an average of 30 percent of calories or less and average saturated fat intake to less than 10 percent of calories in order to help achieve these goals.

B. Reviews From Recognized Scientific Bodies

The National Research Council's 1989 report, "*Diet and Health:* Implications for Reducing Chronic Disease Risk" (Ref. 20) reviewed the role of dietary fats and risk of chronic disease. The report concluded that there is clear evidence that the total amount and types of fats and other lipids in the diet influence the risk of cardiovascular disease (Ref. 20), and that evidence that intake of saturated fatty acids and cholesterol are causally related to CHD (CHD) is especially strong and convincing. The report recommended that persons in the general population limit their intake of total fat to 30 percent of calories and reduce their intake of saturated fatty acids to 10 percent or less of total calories. The report stated that individual responses to dietary cholesterol vary, but noted that, on average, intakes exceeding 100 mg of dietary cholesterol per 1,000 calories elevates LDL-cholesterol by 8 to 10 mg per dL. They recommended limiting dietary cholesterol intake to 300 mg per day or less.

LSRO/Federation of American Societies for Experimental Biology (FASEB) (Ref. 78) prepared an evaluation of the scientific literature on the relationships between dietary lipids and cardiovascular disease, particularly CHD (Ref. 78). The LSRO's conclusions support the major conclusions of the Federal government and other reports from recognized scientific bodies on the role of dietary lipids (saturated fats, other fats, and cholesterol) in the risk of CHD.

With respect to cholesterol, the LSRO report concluded that: (1) Dietary cholesterol may be a greater dietary risk factor than generally realized; (2) almost all individuals respond to dietary cholesterol with at least some rise in serum cholesterol; (3) the danger of high dietary intakes of cholesterol for certain individuals who are high responders to dietary cholesterol may be even greater than the average; and (4) the average increase in serum cholesterol ranges from 6 to 10 mg per dL for each 100 mg cholesterol consumed per 1,000 calories. More recent analysis of epidemiologic data suggests that an increase of 1 mg serum cholesterol per dL, sustained for many years, increases risk of CHD by 1.5 percent. LSRO (Ref. 78) concluded that a strong case, based on circumstantial evidence, implicates dietary cholesterol in atherogenesis, and therefore supports current dietary recommendations to limit dietary cholesterol consumption to less than 300 mg per day.

C. Review of the Scientific Literature

1. Background

CHD is the most common and most serious form of cardiovascular disease. Atherosclerosis is the underlying pathogenic cause in the development of CHD. A relationship between dietary lipids, deposition of cholesterol esters in arterial walls, and CHD was hypothesized early in this century (Ref. 20). Animal studies provided the first direct evidence linking diets high in saturated fat and cholesterol to cholesterol accumulation in atherosclerotic lesions. In this document, the agency reviews pertinent studies relating high intakes of dietary lipids (particularly saturated fats and cholesterol) to elevated serum cholesterol levels and to risk of CHD.

2. Criteria

The criteria used to select pertinent studies required them to be publicly available in English, to present primary data, to include direct measurements or quantitative estimates of dietary lipids, and to include measurements of risk of CHD (incidence and prevalence rates, mortality, or clinical measures of blood total or LDL-cholesterol levels).

In the agency's evaluation of the scientific literature on the relationship of dietary lipids (saturated fat and cholesterol), blood cholesterol levels, and risk of CHD, FDA gave more weight to human studies than to studies in animal models. Because the conclusions of the Federal government and other review documents most consistently identified saturated fat and cholesterol as causally related to CHD risk, a review of studies on other than nonhuman primates and on aspects of cardiovascular disease other than CHD published subsequent to the most recent Federal government reviews, and other reviews by recognized scientific bodies, was not included in this review. Similarly, study results for end points other than CHD or the clinical intermediates of blood total and LDL-cholesterol were also not reviewed due to time constraints and because of the strong focus on these measures in the reports of government and others.

FDA reviewed several types of epidemiologic studies. The strengths and weaknesses of different types of epidemiologic studies and the methodologies for assessment of dietary intakes are reviewed elsewhere (Ref. 20).

FDA generally gave the greatest weight to randomized, double-blind, controlled (placebo or self) clinical trials. Dietary intervention studies conducted for shorter periods of time with fewer subjects were used to support conclusions of large clinical trials. FDA looked for repeated and consistent findings across different types of studies and different population groups. Data were evaluated against general criteria for good experimental design, execution, and analysis. FDA evaluated the weaknesses and strengths of individual studies; then looked at the strength of the overall combined evidence, taking into account the strength of the association, the consistency of findings, specificity of the association, biological plausibility, and dose response. Because of general scientific agreement prior to this review, FDA also looked for consistency or inconsistency with prior conclusions.

The relationships among dietary fats, including saturated fats, cholesterol, and risk of CHD are complex. For this reason, common measures or elements of diet and assessment of risk of CHD were sought in all studies. These measures or elements include the following:

(a) Identification of level of dietary lipids most consistently related to raising levels of blood cholesterol. As a minimum, information on intakes of saturated fat and cholesterol was required;

(b) Identification of commonly used clinical measurements in the assessment of development or progression or risk of CHD. As a minimum, studies were required to have measurements of total cholesterol. Measurements of low density lipoprotein cholesterol (LDL-cholesterol) were deemed desirable;

(c) Observation of clinically manifest CHD including, for example, myocardial infarction, angiographically demonstrated lesions, CHD mortality, and total mortality, were deemed desirable when measures of blood cholesterol were available. These measures were essential in the absence of blood cholesterol data.

3. Dietary Lipids and Risk of CHD

a. *Epidemiologic studies*—i. *Background.* Epidemiologic studies describing the relationship between dietary fats, their effect on blood cholesterol levels, and risk of CHD were described and reviewed extensively in Federal government reports (Refs. 33, 35, and 36), other documents (Ref. 20), and in many reviews cited in these documents. The Federal government and other reviews by recognized scientific bodies concluded that there was strong and consistent evidence that blood total cholesterol and LDL-cholesterol levels are a cause of CHD (Refs. 20, 31, 33, and 36); they estimated that on average, a 1 percent reduction in serum cholesterol is associated with a 1.5 to 2 percent reduction in risk of CHD (Refs. 20, 31, 33, 63, 79, 80, and 147).

FDA reviewed a number of studies and reviews (including meta-analysis of epidemiological and clinical trials) published subsequent to 1987 (Refs. 1, 17, 27, 62, 63, 74, 75, 77, 80, 98, 108, 109, 112, 113, 114, 117, 120, 128, 129, 130, 132, 137, 141, 147) on the relationship of blood cholesterol and CHD and confirmed that more recent studies confirmed and strengthened the previous conclusion.

This section (II. D.) begins with a brief description of two epidemiologic studies reviewed by the Federal government and other reviews by recognized scientific bodies (Refs. 20 and 35) and which describe the relationships between dietary lipids (saturated fat, total fat, and cholesterol) and blood cholesterol levels. The design, results, and conclusions of epidemiologic studies subsequent to the above conclusions are contained in Table I of this document.

In the seven countries study, which was conducted in the United States and six other countries, and included 11,579 men 45 to 49 years of age, 7-day food records and duplicate meals were collected and analyzed to determine the relationship of intake of specific dietary lipids to serum cholesterol (Ref. 35). The results demonstrated a positive correlation between calories consumed from total fat and serum cholesterol levels ($r=0.67$). Correlations between intake of saturated fat and dietary cholesterol and between dietary cholesterol and serum cholesterol were stronger (0.87 and 0.90, respectively). The results of the study showed that there were substantial variations in the amounts and types of fats consumed by different populations. Average blood cholesterol levels and rates of CHD were highly correlated with the percent of calories derived from saturated fatty acids and less strongly correlated with total dietary fat intake. Furthermore, the study provided strong evidence that the risk of CHD is continuous across a wide range of serum cholesterol levels (Ref. 20). The NCEP Expert Panel (Refs. 31 and 33) concluded that this study provided strong epidemiologic support for the relationship between diets high in saturated fat and increased risk of CHD.

The Ireland-Boston Diet-Heart Study (Refs. 20, 35, and 73) was a prospective study of middle-aged Irish men residing in Ireland and brothers who had migrated to Boston. Each group consumed diets typical of their places of residence. Brothers living in Ireland or in Boston who consumed low-fat, low cholesterol diets had similar age-adjusted serum cholesterol levels. The Irish immigrants who adopted the high-fat diet of Boston (16 to 18 percent of calories as saturated fat; 2 to 3 percent of calories as polyunsaturated fat; and 233 to 273 mg cholesterol per 1000 calories) had higher serum cholesterol levels and higher risk of CHD than brothers consuming diets lower in fat and cholesterol. Thus, a positive association was found between dietary intakes of saturated fat and cholesterol and elevated serum cholesterol and risk of CHD among men with similar genetic backgrounds but whose dietary patterns and lifestyles differed.

Based on these and similar results from numerous other studies, the Federal government and other reviews

concluded that an extensive amount of evidence (derived from a variety of types of epidemiologic studies and reinforced by other kinds of research) demonstrated that dietary lipids, particularly saturated fat and cholesterol, are highly correlated with blood cholesterol and rates of CHD (Refs. 17, 27, 108, 109, and 131). Current intake of saturated fat in the U.S. American diet has been estimated to average about 13 percent to 14 percent of total calories (Refs. 20 and 29).

ii. *Update.* FDA reviewed all human studies subsequent to 1987 to determine whether conclusions reached in the Federal government and other reviews by recognized scientific bodies needed to be modified based on the results of more recent findings. In the short review below, studies dealing with omega-3-fatty acids are not considered because the relationship of omega-3-fatty acids and heart disease is the subject of another health claims proposal published elsewhere in this issue of the Federal Register. For reasons discussed previously, reporting of results is limited to dietary intakes of saturated fat and cholesterol relative to blood total cholesterol, LDL-cholesterol, or risk or occurrence of CHD.

In a cross-sectional analysis of 976 African men and women of color aged 15 to 64 years, there was a significant independent correlation between blood total cholesterol and dietary intakes of specific types of fat and cholesterol (Ref. 134). Consumption of diets high in fat and saturated fat (37 and 12.3 percent of calories, respectively) and cholesterol (greater than 310 mg per day) were positively correlated with increased blood cholesterol levels (7.5 millimole (mmol) per l or 290 mg per dL) compared to 4.5 mmol per l (174 mg per dL) in the group that consumed less fat (35.8 percent), saturated fat (10.8 percent) and cholesterol (284 mg per day) (Ref. 134).

The relationship between composition of foods and CHD risk factors, including serum cholesterol, was analyzed in the study by Trevisan et al. (Ref. 139). This cross-sectional study of 10,800 middle-aged men and women in 9 Italian communities (dietary data obtained by questionnaire) showed that higher serum cholesterol levels (5.65 mmol/L; 218 mg/dL) (5.65 mmal/L; 218 mg/dL) were strongly associated with diets high in butter (relatively high in saturated fat and low in other types of fatty acids) (Ref. 139). Additionally, lower levels of blood cholesterol (5.45 mmal/L; 210 mg/dL) were associated with dietary patterns characterized by higher intakes of olive oil and vegetable oil (relatively low in saturated fat and high in polyunsaturated fat and monounsaturated fat) (Ref. 139).

A Belgian study of 5,485 men and 5,456 women showed that in both sexes, higher saturated fat (17.3 percent of calories) and dietary cholesterol (435 mg/day) intakes were associated with higher total cholesterol levels (235 mg per dL) after adjustments were made for lifestyle and physiologic variables using multiple regression-analysis (Ref. 68). Lowik et al. (Ref. 83) studied 199 elderly men and 180 elderly women (65 to 79 years of age) and found a positive correlation between intake of saturated fat (assessed by dietary history) and blood total cholesterol in women but not in men.

Dietary and cross-checked lifestyle questionnaires were used to determine the relationship of diet to serum lipids in 315 free-living Dutch males between 28 and 29 years of age (Ref. 5). The typical Dutch diet contained 39 percent fat, 43 percent carbohydrate and 3282 calories per day. Consumption of a diet high in saturated fat (15.5 percent of calories) and cholesterol (128 mg per 1,000 calories) showed a weak but significant positive association with total serum cholesterol and LDL-cholesterol. Many other epidemiological studies are described in Table 1 which relate diet intakes of dietary fat, especially fatty acid and to blood cholesterol levels (Refs. 28, 40, 51, 70, 83, and 143).

Results of a reanalysis of data collected in the Israeli survey of 8,829 men (40 to 60 years of age) showed a highly significant positive relationship between intake of dietary saturated fat and elevated serum cholesterol. Data were adjusted for intra-individual variability by use of a regression model (Ref. 70).

A prospective study in Japan involving two cohorts of men and women with greater than 2,250 subjects in each cohort monitored dietary animal fat intake and serum cholesterol levels for 7 to 11 years (Ref. 121). At baseline, each cohort was 40 to 69 years of age in 1963 to 1966 or in 1972 to 1975. At initiation of the study, animal fat intake (as determined by random food collection, interviews, and 24-hour dietary recalls) was 4.5 percent of daily calories in the 1963 to 1965 cohort and 9.6 percent of daily calories in the 1972 to 1975 cohort. Serum cholesterol increased 22 mg/dL in men and 29 mg/dL in women which was highly correlated with high intakes of animal fat in every age group and for both genders, but there was no significant change in CHD during the two decades. Serum cholesterol was inversely associated with cerebral hemorrhage in the early cohort.

FDA reviewed meta-analyses and primary data from epidemiologic and clinical studies which analyzed the relationship of lowering of serum cholesterol to risk of CHD (Refs. 12, 14, 16, 17, 42, 63, 76, 85, 86, 106, 130, 137, 141, 146, and 147). Meta-analysis combines data collected with differing methodologies. This complicates data analysis and assessment.

Bush et al. (Ref. 17), in a meta-analysis of nine prospective studies, found that in women a diet low in saturated fat and cholesterol was associated with lower levels of blood total cholesterol and LDL-cholesterol (Ref. 17). Women with total blood cholesterol values greater than 265 mg per dL were at three times greater risk of CHD than women with blood cholesterol below 220 mg per dL.

Shekelle and Stamler (Refs. 120 and 130) reviewed and reanalyzed published epidemiologic studies to evaluate the strength of the effect of dietary cholesterol intakes on serum cholesterol and risk of CHD. The authors evaluated whether dietary cholesterol alone had an independent effect on blood cholesterol. They evaluated four prospective studies (Western Electric study, Ireland Boston Diet-Heart Study, the Zutphen study, and the Honolulu Heart Program) published since 1981. Dietary cholesterol intake in individuals was found to be significantly and positively related to their long-term risk of CHD, independent of, and in addition to, serum cholesterol, blood pressure, and tobacco use. On average, a dietary intake of 300 mg cholesterol per 1,000 calories was associated with a blood cholesterol that was increased approximately 6 to 7 percent. On average, a 200 mg per 1,000 calorie higher intake of cholesterol at baseline was associated with a 30 percent higher CHD rate (95 percent confidence interval).

In summary, recent epidemiological studies evaluated the relationships of dietary fat intakes and blood cholesterol levels. In general, these studies reported significant independent positive correlations between serum total cholesterol and dietary intakes of saturated fat and cholesterol.

There are several detailed recent reviews of this area (Refs. 48, 62, 63, 74, 75, 117, 129, 130, 148). These reports also concluded that there was substantial epidemiologic evidence showing that consumption of dietary fats, especially saturated fatty acids and cholesterol, was highly positively correlated with elevated blood cholesterol and risk of CHD.

b. *Clinical studies*—i. *Background.* Even in very large epidemiologic studies, it is difficult to identify a relationship between dietary intake of a specific nutrient and a disease. One problem is that diets consumed by study participants are not homogeneous, and it is difficult to accurately quantify dietary intakes from dietary recall records. Clinical studies, however, are able to estimate the effects of particular foods or food components with respect to a specific disease process. Clinical trials provide more specific, definitive, and quantitative information on the relationship of dietary components (for example, saturated fat or cholesterol) and to risk factors related to CHD (for example, levels of serum cholesterol).

Federal government reports and other reviews by recognized scientific bodies described and extensively reviewed a wide variety of clinical trials and concluded that the results of clinical trials support epidemiologic studies and show that diets high in saturated fat and cholesterol are strongly correlated with high levels of serum cholesterol (Refs. 20, 31, 33, and 35). These reports also note that some research has also been directed toward identification of specific fatty acids which alter serum cholesterol levels. For example, saturated fatty acids, such as palmitic (C–16), myristic (C–14), and lauric acid (C–12), are more cholesterol-raising than other saturated fatty acids (Ref. 20). However, the reports varied considerably in the emphasis placed on these findings and none of the reviews specifically targeted these three saturated fatty acids when making recommendation for dietary changes by the U.S. population.

The Federal government and other reviews concluded that possible roles of other fatty acids (i.e., monounsaturated fats, polyunsaturated fats) modulating blood cholesterol levels and or CHD risk have been suggested by human studies, but that the evidence is weaker than those roles described for saturated fats and dietary cholesterol.

ii. *Update*—(1) *Dietary intervention to reduce serum.* Dietary intervention trials are reviewed in Table II. The effect of a low fat, low cholesterol diet on serum cholesterol levels, myocardial infarction, and mortality from CHD was assessed in the Minnesota Coronary Survey, a double blind, randomized, open enrollment, dietary trial that included 4,393 men and 4,664 women. The study was conducted in six state mental hospitals and one nursing home (Ref. 42). The patients consumed institution-provided diets for an average of 384 days. Two diets containing 39 percent of total calories as fat were compared. The control diet (a high saturated fat diet) provided 18 percent saturated fat, 5 percent polyunsaturated fat, 16 percent monounsaturated fat, and 446 mg cholesterol per day. The experimental diet (a low saturated fat diet) had less saturated fat (9 percent) and cholesterol (166 mg) and more polyunsaturated fat (15 percent) than did the control diet. Consumption of the low saturated fat diet was associated with a reduction in serum total cholesterol from 207 mg per dL to 175 mg per dL. Serum cholesterol levels in the control group remained at 203 mg per dL. Four and one-half years after starting the diet, however, no differences were observed in the population studied in myocardial infarctions, deaths from CHD, or total mortality. Eighty-one percent of the patients stayed in the hospital less than 1 year. There was, however, a decrease in numbers of deaths and myocardial infarctions in men and women in the 45 to 55 year old subgroup who consumed low saturated fat diets for more than 2 years. A similar change was not observed in the 35 to 39 year old group.

Women, as previously reported in men, with the highest basal serum cholesterol levels achieve the greatest reductions in serum cholesterol upon dietary intervention. In a recent study by Boyd et al. (Ref. 9) of 206 women over 30 years old with monographic dysplasia (breast cancer), half were placed on a low fat (total fat 21 percent, saturated fat 7 percent of total calories, respectively; cholesterol 244 mg per day), high carbohydrate (52 percent of calories) diet for 1 year. Total fat and saturated fat was 37 and 14 percent of total calories, respectively, and cholesterol 344 mg per day in the control diet. In women who consumed the low saturated fat diet, total serum cholesterol levels were significantly reduced by 8 percent at 4 months and serum cholesterol was most effectively reduced in women with the highest basal serum cholesterol levels. No significant changes in serum cholesterol were observed in the control group. The group that received dietary counseling had a significant decrease in body weight and low density lipoprotein cholesterol as well, which was not observed in the group that did not receive counseling.

The effectiveness of dietary instruction on the control of serum cholesterol levels was related in the following study. Curzio (Ref. 26) demonstrated that low fat, low saturated fat, and low cholesterol dietary counseling by trained dietitians' changes in dietary patterns are effective means of reducing serum cholesterol and risk of CHD. Half of 124 hypercholesterolemic and hypertensive patients received dietary counseling regarding low-fat, low-cholesterol diets and half did not (Ref. 26). At baseline the average serum cholesterol for all subjects was 6.5 mmol per 1 (250 mg per dL). Serum total cholesterol, measured two years later, significantly decreased in both groups compared to initial serum cholesterol levels. The group that received dietary counseling had a greater decrease in body weight, total cholesterol (12 percent compared to 8 percent in the control group), and LDL-cholesterol than did the group which did not receive counseling.

(2) *Multifactorial clinical intervention.* The corner stone of multifactorial clinical intervention for reduction in serum cholesterol is low saturated fat and low cholesterol diets as a part of larger lifestyle changes. These multifactorial clinical trials often include several concomitant changes including: the use of a combination of interventions diets low in fat, saturated fat, cholesterol, and sodium, control of high blood pressure, reduction in smoking; stress management; and moderate exercise programs. A 10.5 y followup of the Multiple Risk Factor Intervention Trial (MRFIT), which involved 12,866 men at risk of CHD was recently reported. Half (n=6,428) of the subjects were assigned to special intervention and the other half 6,438 to usual care. A significant decrease (24 percent) in mortality due to acute myocardial infarction and a 7.7 percent decrease in death from all causes (Ref. 101) was observed. This study demonstrates in subjects at risk of developing CHD that multifactorial dietary and lifestyle changes reduce risk. These data can also be cautiously applied to the general population who possess more than two risk factors for CHD.

A small multifactorial intervention trial (71 subjects, 55 who were at high risk of developing CHD) used a low fat-vegetarian diet (6.8 percent of calories) and reported significant regression of coronary lesions (Ref. 106). There was no regression of the disease in control subjects who consumed higher fat diet (29.5 percent of total calories.

(3) *Metabolic studies.* "Metabolic ward" studies are conducted under tightly controlled conditions. Such studies, however, due to their short duration (usually less than 2 months) and small numbers of subjects (usually less than 50 subjects) have less predictive value for determining risk of CHD than do clinical trials. Metabolic ward studies do provide important

information regarding possible specificity, dose-response relationships, short-term effects and possible mechanisms by which dietary fats and cholesterol affect serum cholesterol and risk of CHD. These studies allow for cautious conclusions to be made on the effects of dietary lipids on serum lipids and can be used to confirm inferences derived from clinical studies.

Review of the extensive number clinical trials and clinical trials and metabolic ward studies which have been reported since the publication of the reports by the Federal government and by recognized scientific bodies (Refs. 2, 4, 6, 9, 20, 26, 31, 33, 35, 36, 42 through 45, 53, 54, 57, 69, 82, 88, 89, 92 through 94, 103, 105, 144) are not discussed in detail in the text of this document. Major features and results of a number of these studies are included in Table II, however.

In summary, these studies generally have shown that dietary fat affects blood cholesterol levels in most individuals. Not all dietary fats affect blood cholesterol levels to the same degree or in the same direction. In the majority of studies, dietary intakes in which saturated fat and cholesterol were low relative to basal or control diet showed an association with lower blood cholesterol levels and CHD risk. The nature of most of the studies did not permit conclusions as to links between intakes of specific types of fat (specific saturated fatty acids, monounsaturated, and polyunsaturated fatty acids) and effects on serum cholesterol. Results are, however, consistent with earlier conclusions in the reports by the Federal government and other recognized scientific bodies that diets low in saturated fats are associated with lower total blood cholesterol and LDL-cholesterol.

(4) *Dietary cholesterol and serum cholesterol.* In addition to linking diets high in saturated fat to increases in serum cholesterol levels, the Federal government and other reviews by recognized scientific bodies also concluded that high intakes of dietary cholesterol are associated with higher blood cholesterol levels. Several recent studies have examined this association. Current American intake of dietary cholesterol is approximately 425 mg per day for men and lower for women and children.

Healthy (n=10), free-living, normolipidemic men (average age 27 years) participated in a blinded crossover study designed to determine the effects of dietary cholesterol and exercise on serum cholesterol levels. Subjects who consumed low-fat diets (30 percent of calories with a polyunsaturated to saturated fatty acid constant value of 1.5), exercised aerobically 25 minutes per day, and were supplemented with 600 mg per day of cholesterol for 4 weeks showed increases in LDL-cholesterol compared to subjects fed diets supplemented with 200 mg per day cholesterol (Ref. 66). Individual responses were highly variable but there were significant increases in LDL-cholesterol. Three out of 10 subjects showed an increase in LDL-cholesterol of greater than 2-percent and two showed increases in LDL-cholesterol between 10 and 25 percent.

In a dietary intervention study, 58 free-living subjects previously identified by the authors as "hypo"- or "hyper"-responders to dietary cholesterol were placed on low fat diets (total fat was 29 percent, and monounsaturated fat was 7.5 percent of total calories and polyunsaturated fat to saturated fat content was held constant at a ratio of 1.5). The subjects were challenged with increased dietary cholesterol levels (ranging from 90 to 410 mg cholesterol per day) in a cross-over design (Ref. 41). Those subjects who were responders to saturated fats (blood cholesterol increased more than 8 percent) also showed a small increase in serum total cholesterol and LDL-cholesterol when challenged with increased dietary cholesterol while on 29 percent fat diets. Thus response to dietary cholesterol was not totally dependent on saturated fat intakes. Other dietary cholesterol studies (Ref. 93) are described in Table II.

Segal (Ref. 118), using data from epidemiological and clinical studies, estimated that if individuals reduced consumption of dietary cholesterol from 300 mg per 1000 calories per day to 150 mg of cholesterol per 1000 calories per day without making any dietary change in fat or in total calories, they would experience in a 7.6 mg per dL decrease in blood cholesterol.

In summary, the limited number of dietary cholesterol intervention studies published subsequent to the reports by the Federal government and other recognized scientific bodies show results consistent with those reports, i.e., that dietary cholesterol has an independent effect on serum cholesterol level.

(5) *Individual differences in response to dietary lipids.* The variability in individual responses to dietary lipids is well-recognized (Refs. 20 and 35). Connor (Ref. 21) and Gotto (Ref. 50) reviewed possible mechanisms that may explain variations in individual response to lipids. These authors postulated that each individual may have a threshold amount of saturated fat or cholesterol that when consumed, will increase serum lipid levels (i.e., LDL-cholesterol), and a ceiling amount beyond which further dietary consumption of foods that elevate blood cholesterol will have no effect. The average threshold amount for most people would be 100 mg of cholesterol per day. An average ceiling amount would be approximately 300 to 400 mg per day.

D. Safety Considerations

Reductions in dietary intakes of saturated fat and cholesterol would presumably result in higher intakes of other dietary components (monounsaturated and polyunsaturated fats, carbohydrates, and commercially generated fats) since calories lost from decreased intake of saturated fats must be "made up" by other components. Increased intakes of other types of fats is a possible result. Some of these fats are not metabolized in a manner analogous to common dietary fats and are not generally found in diets to a significant degree.

It is possible that the amount and type of fats available for consumption by the public may change. The agency in its review of the recent scientific literature and comments received by the agency, has identified several areas of possible concern regarding changing American dietary patterns.

1. Trans-Fatty Acids

One area of potential concern is the increasing availability for consumption of trans-fatty acids. Trans-fatty acids (generally isomers of cis monounsaturated fatty acids) are primarily constituents of commercially hydrogenated or hardened natural vegetable oils used in the formulation of margarine, shortenings, salad and cooking oils. Trans-fatty acids may also be found in some meat and dairy products since they are synthesized in the rumen of cattle. Hydrogenation of vegetable oils high in unsaturated fatty acids is used to make oils more palatable or to meet functional needs in food processing. It has been estimated that from 2 percent to 7 percent of beef fat and butterfat, and from 10 to 30 percent of margarine, shortenings and salad oils consist of trans-fatty acids. This is equivalent to approximately 6 percent of total fat consumed in the US or 8.1 g of trans-fatty acids per person per day (Refs. 20 and 65).

The reports of the Federal government and other recognized scientific bodies concluded that most of the evidence indicates that trans-fatty acids, in the quantities currently consumed in the

U.S. diet, do not adversely influence serum cholesterol concentration, and that when substituted for saturated fatty acids, the trans-fatty acids may be associated with a decrease in serum cholesterol (Ref. 20). Studies that examine the effects of trans-fatty acids on serum cholesterol levels are limited, however, and often report conflicting results and conclusions. In addition, there may be other effects unrelated to lipid and lipoprotein metabolism, that deserve careful attention and additional investigation.

LSRO prepared a report on health effects of dietary trans-fatty acids for the agency in 1985 (Ref. 77). In 1885, the estimated average trans-fatty acid content in the U.S. food supply was about 5.5 percent. This level of trans-fatty acids was consistent with that found in human adipose tissue. The data suggested an association rather than a casual relationship.

Studies with individuals fed diets of similar fatty acid composition, except for the replacement of cis isomer (i.e., oleic acid) with the trans isomer (i.e., elaidic acid) of partially hydrogenated vegetable oils, showed that the trans oils were no more cholesterolemic than were the cis isomers (Ref. 77). Similar studies in which elaidic and oleic acid were fed to different experimental groups were not definitive and differences between groups in elevation in serum cholesterol were not significant. Short term studies in animals showed that dietary elaidic acid or partially hydrogenated vegetable are cholesterolemic but not atherogenic (Ref. 77).

In one recent study, the gluteal adipose tissue fat biopsies were removed from 76 free living U.S. males, average age 46.8 years, and analyzed for cis and trans-fatty acids (Ref. 64). No strong correlation was found between concentrations of trans-fatty acids and 10 cardiovascular risk factors, including clinical lipid profiles. The total level of trans-fatty acids in adipose triglyceride was 4.14 percent or equivalent to the proportion consumed in the diet. One isomer 7c–16 carbons:1 double bond (small c represents cis isomer) which is formed from a fatty acid found in hydrogenated shortening (9c–18 carbons:1 double bond) was positively correlated with four risk factors: body mass index, total cholesterol, LDL-cholesterol and systolic blood pressure.

Recently Mensink (Ref. 95) conducted a randomized cross-over design study which included 34 women and 25 men to assess the effect of trans-fatty acids on serum lipids. The average age of the subjects was 25.5 years and all were healthy. The isocaloric diets fat (39 percent of calories, mean calories 2,700 differed in that 10 percent of the total energy was provided as either oleic acid (cis), elaidic acid (the trans form of oleic) or saturated fat (lauric and palmitic acid). Each diet was fed for 3 weeks. The trans-fatty acid diet (saturated fatty acid 10 percent of calories, plus 11 percent additional from trans-fatty acid) increased LDL-cholesterol by 14 mg per dL compared to the oleic acid diet. The diet high in saturated fat (19.4 percent of calories) increased LDL-cholesterol by 18 mg per dL compared to the oleic acid diet (saturated fat 9.5 percent of calories). Trans-fatty acid also produced a small, but significant increase in triglycerides compared to the oleic acid enriched diet. Since the trans-fatty acids increased LDL-cholesterol this could conceivably increase the risk of CHD. The concentration of trans-fatty acid used in the diet was higher than current U.S. consumption. More studies are needed to confirm these results, to determine dose response levels, and to identify populations most sensitive to trans-fatty acids. The issue of the biological effects of hydrogenation of polyunsaturated fatty acid vegetable oils is unresolved.

In its recent evaluation, LSRO concluded on the basis of several reports both prior to 1987 and one major study subsequent to 1987, that there is a strong possibility that trans-monounsaturated fatty acid (i.e., elaidic acid), may raise blood LDL-cholesterol and thus may have atherogenic potential (Ref. 78).

2. Other Safety Considerations

a. *Cholesterol gallstones.* The reports of the Federal government and other recognized scientific bodies conclude that being female and being obese are the factors most consistently associated with gallstones (accumulation of bile supersaturated with cholesterol) (Ref. 20)). There is conflicting and inconsistent evidence regarding a possible effect of diets high in polyunsaturated fats on gallstones (Ref. 20). There is no evidence that intakes of polyunsaturated fats up to 10 percent of total calories affect susceptibility to or induces gallstones in humans.

The relationship of diet and gallstones is reported in the update of the scientific literature. Chileans and some North American Indians commonly consume diets low in both total and saturated fat, but high in complex carbohydrates, and have one of the highest incidence of cholesterol gallstones in the world (Ref. 102). In a study that included twenty healthy 18 to 22 year old Chilean men (described in Table II) consumption of a diet (3219 calories) that contained 120 g per day of legumes reduced LDL-cholesterol (16 percent). Biliary cholesterol saturation increased significantly in 19 of 20 subjects receiving the legume-enriched diet. The authors suggest that the results are consistent with the hypothesis that legumes, (possibly due to nondigestible, saponins) are a potential risk factor for cholesterol gallstone diseases.

b. *Polyunsaturated fats.* Safety concerns associated with consumption of diets enriched in polyunsaturated fats include the following: Long term and increased consumption of polyunsaturated fats may alter membrane fluidity, which in turn, could alter cell membrane function with as yet, undefined results; may decrease levels of high density lipoprotein (a lipoprotein associated with decreased CHD risk) and increase in serum triglycerides (also as yet no firm conclusions); and may increase predisposition to or frequency of certain types of cancer. (In a companion document published elsewhere in this issue of the **Federal Register**, the relationship of dietary lipids, including unsaturated fatty acid such as polyunsaturated fatty acid, and cancer is reviewed relative to health claims.)

It has been suggested that polyunsaturated fats increase formation of lipid hydroperoxides, which in turn could alter or damage cell membranes. Both native and oxidized LDL-cholesterol are hypothesized to cause endothelial cell membrane injury, thus initiating atherogenesis by potentially increasing platelet adherence to blood vessel walls (Ref. 20 and 132). Other dietary components may influence cell membranes also.

In a review article, Steinberg (Ref. 132), pointed out that in vitro studies have demonstrated that oxidized LDL-cholesterol, perhaps resulting from increased hydroperoxides from polyunsaturated fats, is taken up 10 times faster by macrophages [large cells that engulf foreign particles] than unoxidized or native LDL-lipid. Furthermore, antioxidants such as vitamin E inhibited the peroxidation of polyunsaturated fat-LDL-cholesterol in vitro.

Berry (Ref. 6) reported the effects of diets enriched in either monounsaturated fat (oleic acid) or as polyunsaturated fat (linoleic acid) in 26 healthy male college students on blood cholesterol levels and concentration of oxidized LDL-cholesterol. The fat and saturated fat content of both diets was 32 and 8 percent of total calories, respectively. Approximately 17 percent of calories were from monounsaturated

of polyunsaturated fats. Each dietary treatment period lasted for 12 weeks and a 4-week Yeshiva diet was eaten during a 4–week cross-over period between diets. Compliance to the diets was assessed by measurement of fatty acid composition of red blood cell membranes. On the positive side, compared to baseline levels, total cholesterol was significantly reduced by 10 percent consumption of the monounsaturated diet and by 16 percent from consumption of polyunsaturated enriched diet. On the negative side, thiobarbituric acid-reactive substances (i.e., lipid peroxides) in blood increased significantly in the blood (LDL-cholesterol) of subjects who consumed the diet enriched in polyunsaturated fat. The authors suggested that monounsaturated fatty acids may be preferable because they are a poorer substrate for lipid peroxidation than polyunsaturated fatty acids. Other studies reviewed, which examined the effect of dietary polyunsaturated fats on serum lipids including HDL-cholesterol, are found in Table II.

c. *Persons with hypertriglyceridemia.* Although high blood cholesterol levels of lipids known as triglycerides (hypertriglyceridemia) has often been associated with increased risk of cardiovascular disease, the significance of this observation remains controversial (Ref. 20). Dietary changes including increased intakes of simple carbohydrates when fat intakes are decreased may unfavorably alter this condition (Ref. 20).

E. Conclusions

The conclusions of the reviews by the Federal government and by recognized scientific bodies that high blood levels of blood cholesterol and LDL-cholesterol are a cause have been confirmed and strengthened by recently published reports (Refs. 12, 14, 16, 17, 27, 38, 42, 76, 85, 86, 87, 106, 108, 109, 128, 131, 137, and 146). Additionally, earlier conclusions that lower levels in blood cholesterol are associated with the decreased risk of CHD have also been confirmed by recent reports including those of Sprakfa et al. (Ref. 128) and others (Refs. 12, 14, 16, 42, 76, 85, 86, 106, 128, 137, and 146). Estimates from new analysis of epidemiologic data suggest that a one mg per ml increase in serum cholesterol sustained for many years increases CHD risk by about 1.5 percent (Ref. 78). Significant reduction in serum cholesterol (greater than 5 mg per dL) decreases CHD mortality in men and women.

The conclusions of the Federal government and other reviews by recognized scientific bodies that substantial evidence from animal and human studies shows that consumption of dietary fats, especially saturated fats and cholesterol, are highly correlated with elevated blood total and LDL-cholesterol levels and increased risk of CHD were recon firmed and strengthened by research published subsequent to those reports. Recent cross-sectional and prospective studies confirm these conclusions by reporting significant correlations between dietary intakes of saturated fat and cholesterol and increased serum cholesterol (Refs. 5, 17, 28, 68, 134, and 139).

The Federal government reports and other reviews prepared by recognized scientific bodies noted the multifactorial nature of CHD. Factors included high serum cholesterol and LDL-cholesterol, high blood pressure, family history of CHD, cigarette smoking, obesity, sedentary lifestyle, and diabetes were identified as major risk factors.

Diets rich in total fat, saturated fat, and cholesterol increase total serum cholesterol and LDL-cholesterol (Refs. 17, 18, 19, 44, 51, 53, 54, 67, 103, 121, 139, and 140). Estimates from clinical trials and metabolic ward studies suggest that lowering intake of saturated fatty acids by 7 percent of total calories and accompanied by declines in blood cholesterol of 10 to 14 percent should decrease the risk of premature CHD over a decade by about 20 percent, or over a lifetime of 30 percent (Ref. 78).

Potential safety issues relate to possible changes in the relative composition of and amount of fats in the U.S. food supply. Because of lack of long-term safety data on increased consumption of polyunsaturated fats and trans-fatty acids, the Federal government and other reviews by recognized scientific bodies recommend that dietary consumption of polyunsaturated fatty acids remain at current intake levels of 7 percent of calories and should not exceed 10 percent of total calories (Refs. 20, 35, and 78). Intakes of trans-fatty acids were also recommended not to exceed current levels (Ref. 78).

The diet-CHD relationship is very strong and consistent for saturated fat and less so for cholesterol. Diets high in saturated fat and cholesterol are associated with elevated levels of blood total and LDL-cholesterol and consequently of risk of CHD. Diets low in total fat and cholesterol facilitate a reduction in saturated fat and cholesterol intakes and thus are also recommended as useful for lower blood cholesterol levels and for reducing the risk of CHD. A general population approach to reduce total dietary saturated fat, total fat, and cholesterol has been recommended as a practical goal for reducing blood cholesterol and risk of CHD as an achievable goal.

F. Tentative Decision To Authorize Health Claim and Label Statements: Dietary Lipids and Cardiovascular Disease

The agency reviewed the conclusions reached by the Federal government and other reviews by recognized scientific bodies, recent review articles, and the pertinent human and nonhuman primate studies published since 1988. The agency also considered all comments received in response to the request for data and information on the topic of lipids and cardiovascular disease. The totality of the scientific evidence provides strong and consistent support that diets high in saturated fat and cholesterol are associated with elevated levels of blood cholesterol and LDL-cholesterol and with risk of CHD. The general public health support of this concept, as evidenced by all recent dietary guidelines from both the government and other recognized scientific bodies, demonstrates that there is clear, significant agreement among experts qualified by training and experience to evaluate such evidence that the relationship between saturated fat and cholesterol, to blood cholesterol levels and, thus to decreased risk of CHD is particularly strong.

The prevalence of CHD is high in the U.S., and the associated medical and other costs are also high. About 27 percent of adults (male and female; black and white) aged 20 to 74 years of age have blood cholesterol levels in the "high risk" category (total cholesterol greater than 240 mg per dL and LDL-cholesterol greater than 160 mg per dL) (Ref. 119). Another 14 percent have "borderline high" cholesterol levels (total cholesterol between 200 to 239 mg per dL and LDL-cholesterol between 130 to 159 mg/dL) in combination with two or more risk factors. The majority of the American population would benefit from decreased consumption of dietary fat and cholesterol. Extrapolating from the 1986 population data, these observations suggest that 64 million Americans over 20 years of age are candidates for medical advice and intervention. For individuals who have high blood lipid levels, estimates of benefits to be derived from decreased serum lipids include an 8 percent reduction in total cholesterol resulting in a 19 percent reduction in myocardial infarction, and a 7 percent reduction in all cause mortality (Ref. 141).

Dietary fat intakes by the U.S. population are generally considered to be higher than desirable (Refs. 20, 29, 31, 33, and 35). Dietary estimates for American adults show, that average that saturated fat intakes of American adults are about 13 percent of calories, total fat intakes are about 37 percent of calories, and average cholesterol intakes range from 300 to over 40 mg daily for adult women and men. The current intakes of saturated fat and total fat are currently well in excess of recommended goals of less than 10 percent and 30 percent of calories, respectively. Current cholesterol intakes of adult men also exceed recommended goals. The feasibility of meeting recommended fat intakes by the general population was evaluated by a health survey which included 10,348 American men aged 18 and older (Ref. 116). The study results suggested that American adults can successfully follow a low saturated fat, low cholesterol diet without formal consultation with health professionals.

Browner et al. (Ref. 13) made statistical estimates on CHD mortality and total mortality if all Americans (across all ages, sex and race subgroups) reduced total fat intake to 30 percent of total calories as proposed by the Federal government guidelines and health care professionals. The estimates assumed optimal dietary compliance, without allowing for other risk factors or medical intervention. Under these limitations, Browner et al. (Ref. 13) estimated that serum cholesterol levels would decrease by 20 mg per dL. The estimated reduction in risk of CHD mortality was reported to be 5 percent in the elderly and up to 20 percent in younger people. This reduction was projected to result in a 2 percent decrease in all cause mortality. Each individual, based on a 1986 census data, would increase his or her life expectancy by 3 to 4 months. For other individuals, the increase in life expectancy and quality of life would be much greater.

Thus, FDA believes health claims conforming to the proposed regulation will assist those of the general population who wish to select foods reduced in saturated fats, total fats, and cholesterol for reduction in serum cholesterol level and therefore, the risk of CHD.

No deficiency of essential fatty acids or cholesterol or other adverse effects is anticipated from the decreased consumption of dietary lipids (saturated fat, cholesterol and total dietary fat) to levels proposed by the Federal government and other reviews recognized by scientific bodies.

III. Proposed Regulation

A. Scope of Regulation

Based on the totality of the evidence, FDA has tentatively determined that there is and significant scientific agreement among experts qualified by training and experience to evaluate such claims, that consumption of diets high in saturated fats and cholesterol increases total and LDL-cholesterol levels and thus the risk of developing CHD.

The specific health claim topic, as contained in section 3(b)(1)(A)(vi) of the 1990 amendments, is "dietary lipids and cardiovascular disease". FDA, however, limited its review to saturated fats and cholesterol, and to CHD. The agency considered these limitations necessary because of the extremely large volume of research available on the broad topic of dietary lipids and cardiovascular disease, because the scientific data most explicitly supports the lipid nutrient relationship to blood cholesterol levels and thus CHD and finally because CHD is the most serious, primary, and earliest form of cardiovascular disease. In addition, FDA based its selection of saturated fats and cholesterol among the dietary lipids on the conclusions of a number of comprehensive reports by the Federal government and the National Academy of Sciences which identified high levels of these dietary lipids with high blood cholesterol, which is as causally related to CHD. FDA recognizes that considerable research is being conducted on possible roles of other dietary lipids than saturated fats and cholesterol and the risk of CHD. However, time constraints precluded thorough review of these other lipids. Petitions, in accordance with proposed requirements for health claims petitions prohibited elsewhere in this issue of the **Federal Register**, may be submitted to the agency to request that the relationship of other dietary lipid components to CHD, and that other aspects of cardiovascular disease,

B. Relationship Between Dietary Lipids and Cardiovascular Disease and the Significance of the Relationship

Proposed § 101.73(a)(1) describes the relationship between dietary lipids and cardiovascular disease. Proposed § 101.73(a)(2) describes the significance of the nutrient-disease relationship for the U.S. population.

Cardiovascular disease, of which CHD is the most frequently reported manifestation, caused nearly one of every two deaths in the United States in 1987. More than 1 million individuals suffer heart attacks each year, and more than 500,000 die from complications associated with CHD. In contrast, it is estimated that for every 1 percent drop in serum cholesterol levels, there will be, on average, a 1.5 to 2 percent drop in incidence in CHD.

Current dietary guidelines recommend that saturated fat intakes be at or below 10 percent of calories and preferably at 7 percent of calories, and that cholesterol intakes be at or below 300 mg per day. Adults in the U.S. consume, on average, 13 percent of calories as saturated fats. Presently, intakes of dietary cholesterol by American women are at the goal of 300 mg per day but are higher (approximately 400 mg per day) for American adult men.

CHD is associated with a number of risk factors: high blood cholesterol levels, obesity, high blood pressure, cigarette smoking, a family history of heart disease, and physical inactivity. Currently, average serum cholesterol levels in the U.S. are 213 mg per dL for adults. Approximately 25 to 30 percent of the adult U.S. population have serum cholesterol levels above 200 mg per dL.

The significant public health benefits to be derived from decreased consumption of foods high in saturated fats and cholesterol with respect to decreased morbidity and mortality from CHD are based on conclusions reached by Federal government documents such as "The Surgeon General's Report on Nutrition and Health" (Ref. 35) and other reviews by recognized scientific bodies including the National Academy of Sciences' "Diet and Health" (Ref. 20) and reports from the NCEP (Refs. 31, 32, 33, and 34) and supported by FDA's review of the more recent evidence.

C. General Requirements

1. Conformity With 21 CFR 101.14 (General Requirements for Health Claims on Food)

In § 101.73(a)(3)(i), FDA is proposing that health claims relating to an association between dietary lipids (specifically saturated fats and cholesterol) and CHD may be made on the label or in the labeling of a food so long as all the general requirements set forth in § 101.14, proposed elsewhere in this **Federal Register** document, are met. Proposed § 101.14 sets forth such matters as the levels of fat, saturated fat, cholesterol and sodium that would disqualify a food from bearing a health claim and the manner in which a claim must be presented.

2. Qualifying Nutrients: Saturated Fat and Cholesterol

In § 101.73(a)(3)(ii), FDA is proposing that a health claim relating diets low in saturated fats and cholesterol to

reduced risk of CHD would be prohibited unless the food that is to bear a claim meets the requirements of the definitions for "low saturated fat," and "low cholesterol." These requirements are set forth in proposed § 101.62.

The evidence for the association between intake of dietary lipids and blood cholesterol levels, and ultimately to the risk of developing CHD, is strongest for dietary saturated fats and cholesterol. In the proposed "General Requirements for Health Claims for Food" (published elsewhere in this issue of the **Federal Register**), FDA is proposing that for a substance, such as dietary saturated fat or cholesterol, for which decreased levels are needed to achieve dietary goals, the substance be at a low enough level in a food that is a candidate for a claim to justify the claim. It is further proposed that a level that meets the proposed levels for the term "low" be the deciding criteria. In a companion document on "Definitions of Nutrient Content Claims for the Fat, Fatty Acid, and Cholesterol Content of Foods," FDA is proposing that the food contain 1 g or less of saturated fatty acids per label serving size and per reference amount customarily consumed and not more than 15 percent of calories from saturated fatty acids. In that same document, FDA is also proposing that a food can qualify for a "low cholesterol" claim if it contains 20 mg or less of cholesterol per label serving size, per reference amount customarily consumed, and per 100 g of food.

The linkage of dietary saturated fat to blood cholesterol, however, raises questions as to the definition of saturated fats. In another document published elsewhere in this issue of the **Federal Register** ("Supplementary Mandatory Nutrition Labeling"), FDA is proposing to retain the current definitions of saturated fats for nutrition labeling purposes. Saturated fats are defined as the sum of lauric, myristic, palmitic, and stearic acids (C12–C18). Several recent reviews by recognized scientific bodies (Ref. 20) and more recent studies (Refs. 54 and 56) have suggested that the serum cholesterol-raising properties of saturated fats are limited primarily to C12 through C16, and that C18 does not have an appreciable effect on serum cholesterol levels. In response to early agency proposals on content claims for cholesterol and saturated fat (Ref.), and in response to FDA's request for scientific data and information relating to health claims (Ref.), FDA received numerous comments from the food industry requesting that declaration of saturated fat for nutrition labeling purposes be limited to the sum of the three saturated fats most clearly related to serum cholesterol-raising effects (i.e., lauric, myristic, and palmitic).

FDA is aware of this rapidly evolving research area but is proposing not to limit the definition of saturated fats to those most related to adverse effects on serum cholesterol. As noted previously, elevated blood cholesterol is not the only risk factor related to CHD and ultimately to cardiovascular disease. Other saturated fats have also been implicated to increase risk for cardiovascular disease, particularly relative to thrombogenic effects (blood clotting) and related effects which affect blood flow (Ref. 20). For this reason, FDA is proposing not to limit declaration of saturated fats to those related to blood cholesterol.

3. Additional Requirements for Saturated Fats

In proposed § 101.73(a)(3)(iii), FDA is proposing that health claims relating diets low in saturated fat and cholesterol to decreased risk of CHD must also contain saturated fat at levels less than 1 g per 100 g or food.

FDA, as noted above, is proposing to allow the use of the term "low saturated fat" if the food contains 1 g or less of saturated fat per label serving size and per reference amount customarily consumed and not more than 15 percent of calories from saturated fatty acids (see document "Definitions of Nutrient Content Claims for the Fat, Fatty Acid, and Cholesterol Content of Foods" published elsewhere in this use of the **Federal Register**). FDA is proposing the latter criterion in lieu of one based on one tied into the amount of saturated fat per 100 g of food. FDA has explained that it is doing so because the calorie density criterion will allow consumers to make comparisons among fats and oils and thus to aid them in choosing those products lowest in saturated fats when selecting from a category of products whose composition is essentially 100 percent fat. However, for health claims, FDA is concerned that a health claim linking saturated fat and reduced risk of CHD might inappropriately encourage increased consumption of fats and oils with the expectation that they have added health benefit. This is contrary to the recommendations of most current dietary guidelines which unanimously recommend reductions in total fat as well as saturated fat. Thus, FDA is proposing to require in § 101.72(a)(3)(iii) that a food must contain saturated fat at a level of less than 1 g per 100 g of food to bear a health claim.

4. Other Qualifying Nutrients: Low Total Fat

In § 101.73(a)(3)(ii), FDA is also proposing that health claims relating diets low in saturated fat or cholesterol to lower blood cholesterol levels and reduced risk of CHD are prohibited unless the food also meets requirements for a "low" claim relative to total fat content as proposed in the document "Definitions of Nutrient Content Claims for the Fat, Fatty Acid, and Cholesterol Content of Foods" published elsewhere in this issue of the **Federal Register**). In that document, FDA is proposing to define "low total fat" as 3 g or less of fat per label serving size, per reference amount customarily consumed, and per 100 g.

While total fat is not directly linked to increased risk of CHD, it may have significant indirect effects. Low total fat diets facilitate reductions in intakes of saturated fat and cholesterol to recommended levels. Furthermore, obesity is a major risk factor for CHD, and dietary fats, which have more than twice as many calories as proteins and carbohydrates, are major contributors to total calorie intakes. For many adults, maintenance of desirable body weight is more readily achieved with moderation of intake of total fat. The issue of dietary fat and risk of cancer is addressed elsewhere in this issue of the **Federal Register**. This approach is also most consistent with the U.S. Dietary Guidelines and other dietary guidance that recommends diets low in saturated fat, total fat, and cholesterol.

5. Examples of Qualifying Foods

FDA used the criteria for dietary lipids content and sodium to identify foods that would likely be able to bear health claims about the relationship of saturated fat and cholesterol to effects on blood cholesterol, and thus, to risk of CHD. Examples of foods qualifying for a health claim include most fruits and vegetables; skim milk products; sherbets; most flours, grains, meals and pastas (except for egg pastas); and many breakfast cereals. FDA believes that many of these foods are appropriate foods for health claims. However, the agency is concerned that some foods with no apparent nutritive value other than calories (such as candies) would also qualify. FDA solicits comments and suggestions on how to restrict the use of fat/CHD health claims to foods that are generally recognized as part of healthy diets.

D. Specific Requirements for Health Claims

1. Health Claims: Requirements

In § 101.73(a)(4)(i), FDA is proposing that health claims relating dietary lipids to blood cholesterol and CHD must make clear diets low in saturated fat and cholesterol, will reduce blood cholesterol levels which in turn will reduce the risk of developing CHD.

This requirement is based on the effect, as well as the strength, of the scientific evidence regarding the relationship of dietary lipids, especially saturated fatty acids and cholesterol, to risk of CHD. This relationship is extensively documented and summarized in Federal government reports, in other reviews by recognized scientific bodies, and in the science review presented in this document. It shows the intermediate effect of the dietary lipids on blood cholesterol levels and of the blood levels on the risk of CHD. This intermediate effect must clear in any health claim.

2. Variability in Response to Dietary Modification

In § 101.73(a)(4)(ii), FDA is proposing to require that health claims relating diets low in saturated fats and cholesterol to reduced risk of CHD state that most but not all people will reduce blood cholesterol levels with a decreased intake of saturated fatty acids and cholesterol. These responses are variable between, among, and even within individuals, and the variability is greater with respect to dietary cholesterol than to saturated fats.

3. Interchangeable Terms

The scientific evidence most strongly supports a link between dietary saturated fats and cholesterol and CHD. In proposed § 101.73(a)(4)(iii), the agency is proposing to allow manufacturers to use the terms of "CHD" or "heart disease" to name the disease. These terms are terms most commonly used to describe the disease and therefore are expected to be the most understandable for the consumer. Fewer terms are also expected to minimize consumer confusion.

Similarly, to reduce confusion and misleading declarations, the agency is proposing to require the use of the terms "blood cholesterol" or "total blood cholesterol" rather than the more technically correct terms "serum," "plasma cholesterol," or "LDL-cholesterol." The term "blood cholesterol" is more commonly used by consumers and is consistent with terminology in most dietary guidelines. FDA is also proposing to require the use of the dietary terms "saturated fat" and "cholesterol" because these terms are consistent with the terminology on the nutrition label and, therefore, should be less confusing to consumers.

4. Multifactorial Nature of the Disease

In § 101.73 (a)(4)(iv), the agency is proposing to require that health claims identify other risk factors (in addition to elevated blood cholesterol) for CHD. Other modifiable risk factors include high blood pressure, cigarette smoking, physical inactivity, and obesity. These various risk factors appear to act in concert to increase risk. Their effects are at best additive and may in some cases be multiplicative. The agency believes that this additional information provides a basis for the nutrient-disease relationship and will increase consumer understanding of the numerous factors that contribute to risk of CHD.

E. Optional Requirements

In § 101.73(a)(5)(iii), the agency is proposing to allow manufacturers to provide accurate, up-to-date, factual information about the incidence, prevalence or frequency of, morbidity, mortality, cost of health care, etc. data including socio-economic status or educational level, age, sex, or race relating to risk of the CHD. The intent is to provide consumers with such information as will help them understand the seriousness of CHD in the U.S. The source of such information should be the most current and commonly used data from the National Center for Health Statistics. Use of such data will maintain consistency in estimates or statistical data used in the health claim. The source of the data used in the health claim must be identified.

F. Model Health Claims

In proposed § 101.72, FDA is providing four model health messages to help manufacturers to understand the requirements of proposed § 101.72(a) and to help them understand the type of message that FDA considers to be necessary and appropriate.

IV. Appendix to the Preamble—Consumer Summary on Dietary Lipids and Cancer and Dietary Lipids and Coronary Heart Disease

The following appendix is a proposed consumer summary to provide factual information in an easily understandable manner, to assist the consumer in understanding the seriousness of the diet (dietary lipids)/disease (cardiovascular disease) relationship. The role or relationship of dietary lipids (particularly saturated fats and cholesterol) to cardiovascular disease (particularly CHD) is discussed. FDA solicits comments on this document as explained in the proposal on general requirements for health claims published elsewhere in this issue of the **Federal Register.**

Appendix—Dietary Lipids and Cancer and Dietary Lipids and Coronary Heart Disease

Under the provisions of the recent Nutrition Labeling and Education Act, manufacturers may put clear information on the food label about the relationship between a nutrient, such as fat or cholesterol, and a disease or health-related condition. To prevent consumers from being misled, the Food and Drug Administration (FDA) allows only truthful label statements about diet and health relationships that are firmly supported by the current scientific evidence. There is agreement that the scientific evidence is strong enough to allow health claims about the association between total dietary fat and the risk of some types of cancer and the association between dietary saturated fat and cholesterol and the risk of CHD.

Many consumers have said that health claims on food labels could be useful to them in making improvements in their diets. However, label space is often limited. Therefore, this pamphlet provides information about diet and health claims that supplements what you may see on food labels.

In addition to the association between fat and cancer and between saturated fat, cholesterol and heart disease, FDA is allowing health claims about calcium and osteoporosis and sodium and hypertension. For information about these other diet and health relationships, write to: to be inserted.

What is Coronary Heart Disease?

A common usage term for coronary heart disease is heart disease. Coronary heart disease encompasses the heart muscle and its supporting blood vessels. Complications from heart disease results from narrowing of blood vessels (medically called atherosclerosis) and decreased flow of blood to various parts of the body. Myocardial infarction or MI is a medical term used to describe a heart attack.

Atherosclerosis occurs because of raised fatty or fibrous deposits (plaque) that develop in the walls of blood vessels in the affected area. The process of plaque development is gradual, and often begins in childhood.

What is Cancer?

Cancer is not one disease, but more than 100 different diseases. In each of these diseases, cells begin to grow out-of-control at one site in the body, and these abnormal cells spread to other parts of the body.

Why Are Heart Disease and Cancer Major Public Health Concerns?

Coronary heart disease and cancer are public health concerns because they are the two leading causes of death in this country. Illness and death from these diseases cost billions of dollars in health care costs and in lost work. Moreover, early deaths from these two diseases cheat many victims of valuable years of life.

Despite the recent sharp decline in the death rate from this condition, coronary heart disease still accounts for the largest number of deaths in the U.S. Cancer is the second leading cause of death in this country. The leading causes of cancer death are lung cancer, colorectal cancer, breast cancer, and prostate cancer.

What Causes Cancer and Coronary Heart Disease?

Both of these diseases are caused by a combination and interaction of multiple environmental, behavioral, social, and hereditary factors. It is clear that diet, one of the environmental factors, plays an important role in the development of these diseases.

Heredity and other factors, including elevated blood serum cholesterol, cigarette smoking, high blood pressure, obesity and inactive life style, are known to increase a person's risk of developing coronary heart disease. Elevated blood cholesterol, one of the major risk factors for coronary heart disease, is associated with excess fat, especially saturated fat, and cholesterol in the diet.

Many studies have established a strong association between consuming a diet high in saturated fat and cholesterol and increased risk of coronary heart disease. High saturated fat and cholesterol diets are estimated to be associated with one-third of the cases of coronary heart disease reported in this country.

The way diet affects blood cholesterol varies among individuals. However, blood cholesterol does increase in most people when they eat a diet high in saturated fat and cholesterol and excessive in calories. Of these, saturated fat has the greatest effect; dietary cholesterol has less.

Cancer has many causes and several stages in its development. The risk factors for developing cancer include a family history of a specific type of cancer (such as breast, prostate or colon cancer), cigarette smoking, alcohol consumption, radiation, and dietary factors.

Currently, the strongest scientific evidence relating diet to cancer is that the amount of total fat in the diet may have a relationship with cancer. In particular, many experts agree that a high fat diet may influence the risk for developing breast, colon, and prostate cancers.

Not enough is known currently for scientists to decide whether different kinds of fats (animal or vegetable; saturated or unsaturated) may be responsible for an increased risk of developing cancer.

Because of scientific agreement that reducing total fat and saturated fat is likely to lower the rates of these two major chronic diseases, it is recommended that Americans 2 years of age and older choose a diet low in total fat and saturated fat. Animal products are the source of all dietary cholesterol. Eating less fat from animal sources will help to lower the cholesterol as well as the saturated fat in your diet.

Do Most People Get Too Much Fat, Saturated Fat and Cholesterol in What They Eat?

The average U.S. diet, it's estimated, contains about 37 percent of calories from total fat, 13 percent of calories from saturated fat, and 360 mg of cholesterol per day. Health experts recommend diets that contain 30 percent or less of calories from total fat, 10 per cent or less of calories from saturated fat, and 300 mg or less of cholesterol a day. The U.S. Public Health Service has set a national health goal that all persons who are 2 years of age and older consume these levels of fat and cholesterol by the end of this decade.

How Do You Learn How Much Fat and Cholesterol Foods Contain?

You may or may not be able to tell that there's fat in a food by looking at it. Butter, margarines, shortenings, and oils are the more obvious sources of fat. In other foods, such as cheese, baked goods, nuts, and salad dressings, the fat isn't as easily detected. Cholesterol content is not obvious at all in foods.

A good way to learn about fat and cholesterol content is to read nutrition labels. Most foods now have nutrition information on their labels.

The amounts of total fat and saturated fat in a serving of food are listed in grams (g) on the nutrition label. Cholesterol is listed in milligrams (mg).

"Daily values" for fat, saturated and cholesterol also appear on food labels. These numbers have been established by FDA for several nutrients that are important in diet and health relationships. The daily values are to help you learn how the amount of a nutrient in a serving of food relates to a reasonable amount for the day.

The daily value for total fat is 75 g, and for saturated fat is 25 g. That means total fat for a day of 75 g, of which no more than 25 g should be from saturated fat. These numbers are based on a 2350-calorie diet that has 30 percent of calories from fat and 10 percent from saturated fat. A 2350-calorie diet is about the calories recommended for an adult woman.

If you consume a different number of calories a day, it's not hard to figure out your own daily values for total fat and saturated fat. First, multiply the number of calories you consume by 30 percent (for example, 2000×.30=600). Then divide that number by nine, which is the number of calories each g of fat provides (600 divided by 9=67 g of fat a day). Repeat for saturated fat (2000×.10=200; 200 divided by 9=22 g of saturated fat a day).

The daily value for cholesterol is 300 milligrams, which is an upper limit that's generally recommended for healthy people. A food that contains 150 milligrams of cholesterol per serving, therefore, would provide about half of the daily value for cholesterol.

What Do Label Claims About Fat and Cholesterol Mean?

In addition to the amount of fat and cholesterol listed on the nutrition label, you may see other claims about fat and cholesterol content on some food packages. There are two types of these claims—nutrient content claims and health claims.

Nutrient content claims describe the amount of fat, saturated fat or cholesterol a food contains. These types of claims can be used on a label only if a food meets several definitions established by FDA.

Cholesterol claims

- A "cholesterol free" food has less than 2 milligrams of cholesterol and 2 grams or less of saturated fat in a serving.
- A "low cholesterol" food has 20 milligrams or less of cholesterol in a serving and in 100 grams of food and 2 grams or less of saturated fat in a serving.
- A "reduced cholesterol" food has its cholesterol content reduced by 50 percent or more compared to the regular

food product and contains 2 g or less of saturated fat in a serving.

Cholesterol claims may be made only on foods that contain a limited amount of fat (no more than 11.5 g per serving and per 100 g) unless the claim also tells the total amount of fat, for example, "cholesterol free, contains 12 g of fat per serving."

Fat claims

- A "fat free" food has less than a half g of fat in a serving and no added fat or oil.
- A "low fat" food has 3 g or less of fat in a serving.
- A "reduced fat" food has a 50 percent or more reduction in fat with at least a 3 g reduction in fat content.
- A "low saturated fat" food has 1 g or less of saturated fat in a serving and no more than 15 percent of its calories from saturated fat.
- A "reduced saturated fat" food has its saturated fat content reduced by 50 percent or more compared to the regular food product with at least a 1 g reduction in fat.

Also, the labels of some foods in which fat or cholesterol has been significantly reduced, but not enough to meet the definitions above, may have a statement that tells how much less fat or cholesterol the product contains than a comparable product; for example, "This pound cake contains 40 percent less fat than our regular pound cake."

Foods such as fruits and vegetables that meet the definitions for fat or cholesterol without special processing may have claims on them. However, the label must say that fat or cholesterol isn't usually present in the food, for example, "broccoli, a fat-free food," "frozen perch, a low fat food," or "raspberries, a low saturated fat food."

Health claims are those made about the relationship between the amount of a nutrient you eat and the risk of a disease, for example, between total fat and cancer or between saturated fat and cholesterol and heart disease.

Health claims about the relationship between fat and cholesterol and heart disease can only be made on products that are low in saturated fat and cholesterol, and have 15 percent or less of their calories from fat. To make a health claim, the product also cannot contain another nutrient that increases the risk of a diet-related disease other than atherosclerosis, for example, a high amount of sodium which has a relationship to high blood pressure.

Health claims about the relationship between fat and cancer can be made only on foods that are low in fat and do not contain another nutrient that increases the risk of a diet-related disease other than cancer.

These are some of the kinds of foods on which you may see health claims about nutrients related to cancer and heart disease: fruits, fruit juices, vegetables, breakfast cereals, dried peas and beans, skim milk, pasta products, and diet salad dressings.

Other Risk Factors for Cancer and Heart Disease

Coronary heart diseases and cancer are complex diseases with multiple causes, and they (usually) develop over a long period of life. Hereditary as well as environmental factors contribute to the risk for developing these diseases. In addition to practicing good nutrition, several other controllable factors are part of a healthy lifestyle and may help to decrease your chances of cardiovascular disease and cancer. These include maintaining a healthy body weight and good physical fitness, not smoking cigarettes, drinking only in moderation if at all, and not abusing drugs.

Facts to Keep in Mind

- It's the total combination of foods that you eat regularly—both the kinds and the amounts—that's important in terms of good nutrition. Eating a particular food or a specific food isn't a magic key that will assure you have a more healthful diet.
- Eating a healthy diet, in itself, doesn't guarantee good health. A healthy diet, however, is an important part of a healthy lifestyle.
- In addition to what you eat, many factors may be related to your own chance of developing a particular disease, for example, your heredity, your environment, and the health care that you get. Our knowledge about most diet-health relationships is incomplete, and will improve as scientific knowledge increases. However, enough is known today about some of these relationships to encourage specific dietary practices that are believed to be beneficial.

VI. Environmental Impact

The agency determined under provisions found in 21 CFR 25.24(a)(11) that this action by the agency is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environment impact statement is required.

VII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

VIII. Effective Date

FDA notes, however, that in section 10(a)(3)(B) of the 1990 amendments, Congress provides that if the Secretary, and by delegation FDA, finds that requiring compliance with section 403(q) of the act, on mandatory nutrition labeling, or with section 403(r)(2) of the act, on nutrient content claims, 6 months after publication of the final rules in the **Federal Register** would cause undue economic hardship, the Secretary may delay the application of these sections for no more than 1 year. In light of the agency's tentative findings in its RIA that compliance with the 1990 amendments by May 8, 1993, will cost $1.5 billion, and that 6 month and 1 year extensions of that compliance date will result in savings that arguably outweigh the lost benefits, FDA believes that the question of whether it can and should provide for an extension of the effective date of sections 403(q) and (r)(2) of the act is squarely raised.

FDA has carefully studied the language of section 10(a)(3)(B) of the 1990 amendments and sees a number of questions that need to be addressed. The first question is the meaning of "undue economic hardship." FDA recognizes that the costs of compliance with the new law are high, but those costs derive in large measure from the great number of labels and firms involved. The agency questions whether the costs reflected in the aggregate number represent "undue economic hardship."

Therefore, FDA requests comments on how it should assess "undue economic hardship." Should it assess this question on a firm-by-firm basis, as was provided in the bill that passed the House Committee on Energy and Commerce (H. Rept. 101–538, 101st Cong., 2d sess., 24 (1990)), an industry-by-industry basis, or should it assess this question on an aggregate basis? If the agency should take the latter approach, comments should provide evidence that would permit the agency to make a determination that there is "undue economic hardship" for most companies. FDA also points out that assessing hardship on a firm-by-firm basis would likely be extremely burdensome because of the likely number of requests.

FDA will consider the question of the meaning and appropriate application of section 10(a)(3)(B) of the 1990 amendments as soon as possible after the comment period closes. The agency intends to publish a notice in advance of any final rule announcing how it will implement this section to assist firms in planning how they will comply with the act. The early publication of this notice is to assist firms in avoiding any unnecessary expenses that could be incurred by trying to comply with a compliance date that may cause "undue economic hardship."

IX. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. to 4 p.m., Monday through Friday.

In accordance with section 3(b)(1)(B) of the 1990 amendments, FDA must issue by November 8, 1992, final regulations for mandatory nutrition labeling. If the agency does not promulgate final regulations by November 8, 1992, the 1990 amendments provide that the regulations proposed in this document shall be considered as the final regulations. The agency has determined that 90 days is the maximum time that it can provide for the submission of comments and still meet this statutory timeframe for the issuance of final regulations. Thus, the agency is advising that it will not consider any requests under 21 CFR 10.40(b) for extension of the comment period beyond February 25, 1992. The agency must limit the comment period to no more than 90 days to assure sufficient time to develop a final rule based on this proposal and the comments it receives.

List of Subjects in 21 CFR Part 101

Food Labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Sec. 4, 5, 6, of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701, of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. New § 101.73 is added to subpart E to read as follows:

§ 101.73 Health claims: lipids and cardiovascular disease and lipids and cancer.

(a) *Coronary heart disease*—(1) *Relationship between dietary lipids (primarily saturated fat and cholesterol) and coronary heart disease:* Diets high in the lipid components, saturated fat and cholesterol are associated with increased levels of blood cholesterol and, thus, increased risk of developing coronary heart disease. Reductions in intake of saturated fats and cholesterol are associated with decreased levels of blood cholesterol and lower risk of developing coronary heart disease.

(2) *Significance of the relationship between saturated fat and cholesterol and risk of coronary heart disease.* The cost of coronary heart disease in the United States is considerable in terms of morbidity, mortality, direct health care expenditure and loss in productivity. Substantial improvements in the quality of life and significant reductions in health care costs can result from reducing the morbidity and mortality associated with coronary heart disease. Early management of risk factors for

coronary heart disease can aid in achieving this major public health goal for which national, population based recommendations to reduce risk of coronary heart disease and other forms of cardiovascular disease have been made. One of the major recommendations is to decrease consumption of dietary fat, especially saturated fat and cholesterol.

(3) *General requirements.* A health claim associating a diet low in saturated fat and cholesterol with decreased risk of coronary heart disease may be made on the label or labeling of a food provided that:

(i) All requirements set forth in § 101.14 are met;

(ii) A serving of the food meets the requirements of § 101.62 for:

(A) "Low saturated fat,"

(B) "Low cholesterol," and

(C) "Low fat."

(iii) The food contains 1 gram or less of saturated fat per 100 grams.

(4) *Specific requirements.* The health claim would be prohibited unless the following requirements are met:

(i) The health claim shall state that a diet low in saturated fat and cholesterol will reduce high blood cholesterol and, thus, reduce the risk of coronary heart disease.

(ii) The health claim shall state that a diet low in saturated fat and cholesterol will reduce high blood cholesterol in some individuals but not in all;

(iii) The health claim shall use the following terms:

(A) For the disease: coronary heart disease or heart disease;

(B) For lipid levels: Blood cholesterol or total blood cholesterol; and

(C) For dietary terms, saturated fat(s); or cholesterol.

(iv) The health claim may indicate that coronary heart disease is a multifactorial disease. It may identify major risk factors:

(A) A family history of coronary heart disease;

(B) Those who have elevated blood cholesterol levels;

(C) High blood pressure;

(D) Those who smoke cigarettes

(E) Those who are obese (greater than 30 percent above ideal body weight);

(F) Those who have diabetes; and

(G) Those who are physically inactive.

(5) *Optional information.* The health claim may provide the following information.

(i) The health claim may state that individuals with elevated blood cholesterol, a family history of coronary heart disease, or those with multiple risk factors for coronary heart disease should seek medical advice and guidance; and

(ii) The health claim may include information on the number of people in the United States who are at risk or who have been diagnosed as having coronary heart disease or may include information on morbidity and mortality associated with coronary heart disease. The sources of such information must be identified, and be current (as found in information from the National Center for Health Statistics).

(6) The following are four sample health claims that may be used in food labeling to describe the relationship between dietary lipids and cardiovascular disease:

Four Sample Health Claims

1. Diets low in saturated fat and cholesterol, as part of well balanced diets and healthy lifestyles, will reduce elevated blood cholesterol and lower the risk of developing heart disease in most individuals. Individuals at highest risk include those with a medical history of heart disease, hypertension, or who have blood cholesterol levels greater than 200 mg per dL. Other risk factors include: inheritance of premature coronary heart disease, smoking, obesity, diabetes mellitus, and sedentary lifestyle.

2. Heart disease is associated with many risk factors including: a family history of premature heart disease, high blood cholesterol, hypertension, cigarette smoking, obesity and consumption of diets high in saturated fat and cholesterol. A healthful diet low in saturated fat, total fat, and cholesterol will lower blood cholesterol and reduce the risk of heart disease in most people.

3. Developing heart disease depends upon many factors, including a family history of the disease, high blood cholesterol, high blood pressure, being overweight, cigarette smoking, lack of exercise, and diets high in some types of fat. A healthful diet low in saturated fat, total fat, and cholesterol and a healthy lifestyle will lower blood cholesterol levels and reduce the risk of heart disease in most people.

4. High blood cholesterol is a major cause of coronary heart disease. Other important factors are a family history of heart disease, being overweight, high blood pressure, and cigarette smoking. A healthy diet low in saturated fat, total fat, and cholesterol will lower blood cholesterol levels and reduce the risk of heart disease in most people.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Abbot 1988 (Ref 1).	Prospective, Framingham Study.	2425 men and women; 50 to 79 years; Multiple risk factors: BP, Wt, smoking, HDL-C, TC, estrogen.	12 year	N/A	Importance of HDL-C; possible to have high TC of which HDL-C make it high and have decreased risk of CHD; (men HDL-C 53 to 129 mg/dl or women 47 to 55 mg/dl reduce risk of CHD); HDL-C protect women who are above 50 years old HDL-C less than 46 mg/dl 6 times increased risk women of CHD for men less than 53 mg/dl results in 60 to 70% chance of MI.	Protective effect of HDL-C in men and women varies with age estimates relative risk reduction.

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Burke 1991 (Ref. 15).	Cross-sectional	Minnesota residents 25 to 74 years old, both sexes; first survey in 1980 to 82 had a population of 3365; second survey in 1985 to 87 consisted of a population of 4545.	N/A	Part of the Minnesota Heart Survey. This survey is more focused upon examining concurrent community trends in awareness of heart disease and preventive factors. Dietary survey methods are not discussed in this paper.	In both men and women, the distribution of cholesterol levels decreased from 1980 to 1982 to 1985 to 1987. The greatest decline in serum total cholesterol was observed in the 65 to 74 year olds.	The survey is not applicable to the questions of dietary causes of heart disease.
Bush 1988 (Ref. 17).	Prospective re-analysis of the relationship of diet to serum cholesterol in women.	Analysis of data for women from 9 prospective studies: (Framingham, Tel Aviv, NHANES) with emphasis on HDL-C.	variable	N/A	Women with greater than 265 mg/dl TC are at 3X greater risk of MI; HDL-C is strongly negatively correlated and is an independent predictor of CHD in women. For each 10 mg/dl reduction in HDL, there is a 50% decrease in MI; low cholesterol diet or high P/S diets in women decrease TC, LDL-C, and HDL-C; obese women have high TC, LDL-C and low HDL-C.	HANES survey showed no association between dietary and serum cholesterol
Dagenais 1990 (Ref. 27).	Prospective	4576 men, 35 to 64 years; Multi-factors; end points first event CHD, angina, MI, CHD death. Subjects free of heart disease at beginning of study.	12 year	Baseline history through questionnaire, complete medical evaluation to rule out CVD. Cardiologist diagnosed angina, enzyme levels, EKG, MI, autopsy data.	Adjusted data for age High serum cholesterol was positively correlated with the first coronary event, but not CHD mortality. Two-thirds of CHD incidence is due to elevated blood pressure, smoking and high serum cholesterol.	Since elevated BP is a risk factor in CHD, antihypertensive medications may be a confounding risk factor. Well-controlled.
Dyerberg 1989 (Ref. 40).	Cross-sectional study of dietary fats and serum lipids in two population groups (in Greenland and Denmark).	45 to 64 year old Danish men and Greenland Inuit men.	25 years of data.	Laboratory analysis of blood; morbidity data, which the author admits is not as good among the Inuits as the Danes.	Inuits: Fat energy, 39%; P/S ratio, .84; n-3 PUFA 14g/day Danes: Fat energy, 42%; P/S ratio, .24; n-3 PUFA, 3g/1 day. Although the Inuits have higher fat intake than Danes, Danes have a 13:1 incidence of acute MI, compared to Greenlanders. There is a highly significant difference (<.005) between the Danes and Inuits in all of the following parameters: cholesterol, triglycerides, LDL, VLDL, and HDL.	Uncontrolled for other risk factors, such as genetic and lifestyle differences.
Gramenzi 1990 (Ref. 51).	Case-control study of impact of diet on CHD.	Cases: 287 Italian women, with history of acute MI; average age 49; 649 Controls: patients from 30 hospitals.	5 years	Food frequency and lifestyle questionnaire.	Acute MI was strongly associated with frequency of consumption of meat, ham, salami, butter, total fat added to food and coffee. A slight inverse relationship was observed between consumption of fish, carrots, green vegetables and fresh fruit.	Questionnaire was verified by telephone in only 10% of cases. Insensitive dietary collection (Food frequency reported as low, medium, or high).

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Kesteloot 1989 (Ref. 68).	Cross-sectional	Stratified random sampling in 42 counties of Belgium which yielded 5485 men and 4856 women.	Cross-sectional	Data on nutrition were obtained by a 24 hour food record method.	In both sexes, saturated fat intake increased both total cholesterol and HDL-cholesterol. Also, in both sexes, there is an inverse relationship between polyunsaturated fat intake and HDL-cholesterol. Dietary cholesterol makes no independent contribution to total serum cholesterol but increases HDL-cholesterol in women.	Adjustment through multiple regression analysis for age, height, weight, alcohol and cigarettes. Other lifestyle variables and other food components should be included in the model.
Keys 1988 (Ref. 70).	Cross-sectional re-analysis.	8829 Israeli men, 40 to 60 years.	N/A	In the original study, Israeli men were divided into 6 groups, based on region of birth. The serum cholesterol was measured only once. Keys redid the analysis of the original Israeli study, using a regression model he developed with schizophrenics.	When intra-individual variation is corrected, a highly significant relationship between mean dietary fatty acid consumption and mean serum cholesterol appears.	Keys' point that the relationship between serum cholesterol and dietary fat can not be understood by a one-time serum cholesterol measurement is well-taken. His model, which was developed in schizophrenics, has questionable representativeness. The authors from the original study have not responded.
Lowik 1991 (Ref. 83).	Cross-sectional study of dietary fats and serum cholesterol.	539 healthy elderly (aged 65 to 79y) Dutch individuals; after exclusion of those using cholesterol-lowering drugs, antidiabetic medication, and those on a dietary regimen, 199 men and 180 women remained.	N/A	Nutritional survey within the Dutch Nutrition Surveillance System; food consumption data.	Among men, intake of monounsaturated fat was positively and consistently associated with serum total cholesterol. Among women, intake of saturated fat was positively associated with serum total cholesterol.	This is a correlational study, and therefore does not look at individual outcomes. Since elderly people on a diet were excluded, those responsive to high-cholesterol diets may have been underrepresented. Confounding was well-controlled.
Mitchell 1989 (Ref. 97).	Prospective study	3301 Mexican-Americans (1393 men, 1908 women); 1877 non-Hispanic whites (835 men, 1042 women), 25 to 64 years of age.	9 years	Mean levels of cardiovascular risk factors were computed, and each subgroup was given a cardiovascular risk score. ECG's have been obtained on all subjects, and coding according to the Minnesota criteria has now been completed on all diabetic subjects.	In both men and women, triglyceride, and HDL-C was lower in Mexican-Americans than in non-Hispanic whites after controlling for age and sex, non-Hispanic white diabetics were 2.3 times as likely (no CI reported) as Mexican-American diabetics to have ECG evidence of MI.	The current risk factors might not fully capture lifetime exposure to risk factors. Current risk factors might not account for all the variance in CV outcome. Currently, only detailed information on diabetics has been compiled and analyzed; would like to see completed study on healthy individuals.

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Pekkanen 1990 (Ref. 108).	Prospective study of serum lipids and CHD mortality.	2541 white men, ages 40 to 69; both free of and with a history of CVD.	10.1 years follow-up.	Baseline measurements obtained as part of the Lipids Research Clinics Program Prevalence Study, annual follow-up for mortality, not intervention. Vital status is currently known for over 99.6% of participants.	Among those with CVD at baseline, those with high TC levels (>6.19mmol/l), had a risk of death from CVD (including CHD) 3.45 times higher (95% CI 1.63 to 7.33) than those with desirable total cholesterol(TC) (<5.16 mml/l) For LDL-C: a RR of 5.92 (95% CI 2.59 to 13.51) for >4.13 mmol/l compared to <3.35 mmol/l. For HDL: a RR of 6.02 (95% CI 2.73 to 13.28) for <.90 mmol/l compared to 1.16 mmol/l. TC and LDL-C levels were also sign. predictor of death from CVD in men without preexisting CVD, but at a lower level of absolute risk of death. 10 year.	Well-controlled study. Measurements were complete; dropout rate extremely low.
Pocock 1989 (Ref. 109).	Prospective study of relationship of werum lipids to ischemic heart disease. British Regional.	7725 British men, age 40 to 59 years.	7.5 years.....	Blood samples, standardized for hr of day; morbidity and mortality documented elsewhere.	An increase in TC is associated with a significant increase in the risk of ischemic heart disease. A decrease in HDL is associated with a significant increase in the risk of ischemic heart disease. Triglycerides are not a predictor of ischemic heart disease once other factors are controlled.	Study is well-controlled
Reed 1990 (Ref. 110).	Prospective study of serum choleseterol and CHD.	514 sets twins, male, age 42 to 55 family history of CHD, TC, HDL-C, physicians records, death certificates.	14 to 18 year.....	Used 2 way analysis of variance.	Family history of ischemic heart disease is significantly and independently correlated with ischemic heart disease. Family history is a better predictor of heart disease than blood lipids.	Well-controlled study. Data collected and analysis carried out very precisely.
Shimamoto 1989 (Ref 121).	Prospective study of the relationship of animal fat intake to CHD.	2 cohorts: 1. 2257 men and women, ages 40 to 69 at baseline, followed from 1963 to 1966 to 1973. 2. 2711 men and women, ages 40 to 69 at baseline, followed from 1972 to 1975 to 1983.	7 to 11 years.....	Surveillance through investigation all hospitalized cases plus six other ascertainment sources: national insurance claims, reports by local physicians, ambulance records, death certificates, reports by public health nurses and health volunteers, and risk factor surveys.	Animal fat intake doubled in men ages 40 to 59 from 4.5% of daily calories in 1969 to 9.6% in 1980 to 1983; significant upward shifts occurred in the means and distribution of serum total cholesterol and serum total protein in every age and sex group. Age-adjusted incidence from CHD shows no significant change overall during the 2 decades. For men and women ages 70 and older, there was no significant trend for CHD incidence except sudden death and all CHD in women, which increased significantly.	This study examines many risk factors and many outcomes (all CHD, and hemorhhagic stroke, and cerebral infarct). The nutrition survey were administered to a sample of the men. Nutritional intake was calculated by a standard Japan Food Tables. The portion of the study that relates diet to outcome uses ecologic data, which suffers from ecologic fallacy.

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Slattery 1988 (Ref. 123).	Ecological comparison: CHD mortality and food consumption trends Fat content (SA) used.	Individuals who died of CHD and dietary data during the same period.	1909 to 1989 (71 years).	Dietary data: 1. Food balance sheets. 2. Food disappearance data. 3. Household surveys from Food Agriculture Organization, Economic Research Service USDA Population data vital statistics publication.	Up to 1950 increase in CHD mortality in 45 to 54 year old and 55 to 64 year age groups. Mid 1960's to 1978 decline in CHD mortality in same age groups. Percent of total calories from fat increase from 1090 to 1960. Fats and oils contributed to 40% of total dietary fat.	Limitation on availability of accurate dietary data Ecological data does not prove causal relationship. Latency period between change in diet and change in risk of CHD (10 to 20 year). Data did suggest a trend toward decrease in SFA and cholesterol preceded national decline in CHD.
Sprafka 1990 (Ref. 128).	Cross-sectional study of serum cholesterol and CHD mortality.	A set of Minnesota residents age 25 to 74 in 1980 to 82, and another set age 25 to 74 in 1985 to 1987.	N/A.....	Analysis of covariant means and frequency distributions.	Between 1980 to 1982 and 1985 to 1987, serum total cholesterol declined significantly by 5.2mg/dl in men and 5.8 mg/dl in women. HDL decreased 1.6 mg/dl in men and 0.9 mg/dl in women. The mortality from CHD declined 20.1% in men and 12.9% in women from the 1981 survey to the 1985 one.	Multiple confounders not adjusted.
Stephen 1990 (Ref. 133).	Cross-sectional	Total US population studies included 8 to 20,000 subjects all ages, both sexes.	64 years.....	Results were compiled from all the studies carried out in the United States in which assessment of individual dietary intake had been carried out and where information on fat intake had been reported.	Fat intakes rise from 34% energy in the 1930's to 41% in 1960, then falling steadily to 36% energy in 1984. This trend was seen for all age and sex groups. These results differ markedly from food supply trends and indicate a fall in U.S. fat intake, which preceded the decline in heart disease mortality.	The data here is consistent with fat intake being a factor in heart disease. This study is of value to show that data gathered from food balance figures are misleading, by not allowing for waste or spoilage and includes food used for purposes other than human consumption.
Steyn 1990 (Ref. 134).	Cross-sectional study of dietary intake and serum lipids.	976 racially-mixed subjects aged 15 to 64.	Cross-sectional ..	Food intake was calculated from a dietary questionnaire, which included a 24-hour dietary recall. Multiple linear regression was carried out from men and women separately.	There was a significant independent correlation between serum total cholesterol and the following: dietary intake of saturated fat, intake of polyunsaturated fat, the P/S ratio, and the intake of cholesterol.	This study uses within-population data, rather than international comparison. Although this reduces the effect from genetic and environmental differences, there are still many unknown factors, which may impact upon the relationship between nutrients and total serum cholesterol.
Sytkowski 1990 (Ref. 137).	Prospective study of serum lipids and CHD.	3 male cohorts, who were 50 to 59 year old in 1950, 1960, 1970. No. subjects in each: 485, 464, 514.	Each cohort was followed for 10 year.	Risk factor assessment TC, BP, smoking, stress management.	43% reduction in 10 year risk of death from CVD in 1970 compared to 1950 group; and a 60% reduction in 10 year mortality rate in those who were free of CVD at base line. Risk factors status in 1970 and 1950 groups; from base line TC dropped 22 vs 12 mg/dl; smoking decreased 56% vs 34% and hypertension decreased from 36% vs 20%.	Well-controlled study. A decline in incidence of CVD and improved medical interventions can not be ruled out as contributing to the decline in mortality.

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Trevisan 1990a (Ref. 139).	Cross-sectional study of dietary fats and serum lipids.	4903 Italian men and women, age 20 to 59 year; part of the Italian Nine Communities Study.	N/A	Interview administered PUFA and CHD risk, food frequency.	Increase in frequency of consumption of butter correlated with increase in serum cholesterol and glucose in men and with glucose in women. Olive oil and vegetable oil intake is inversely associated with serum cholesterol, glucose and systolic blood pressure	Data was adjusted for many confounders. The Italian population does not consume very much corn, or sunflower oil. This study grouped corn, soybean and sunflower oil all as PUFAs. Frequency of consumption of 53 food items, then selected top 14 of the 35 to use to calculate atherogenic index and amount (small, medium or large).
Trevisan 1990b (Ref. 140).	Cross-sectional study of diet and serum cholesterol.	10,800 men and women, ages 20 to 59, randomly selected from each of nine communities throughout Italy.	Cross-sectional	Interview-administered food frequency questionnaire.	In both sexes, serum cholesterol increased with higher consumption of foods with high fat content. These findings were independent of any possible confounding effect of age, adiposity, alcohol intake and cigarette smoking.	The detail of the food questionnaire was not sufficient to conclude that fat as a specific nutrient is responsible for the increase in the individual risk.
Van Horn 1990 (Ref. 143).	Multicenter cross-sectional study of the relation of diet to serum lipids.	5111 free-living men and women, black and white, 18 to 30 years old during the period 1985 to 1986.	1 year	Assessment interviews clinical lipids psychosocial anthropometric.	Part of CARDIA Study, fat consumption significantly correlated with serum cholesterol in white men and women age 28 to 30 BMI was positively, significantly correlated with TC, LDL-C in all race and sex groups Education was positively associated with HDL-C in black and white men and women. HDL was negatively associated with carbohydrate regardless of race and sex in 25 to 30 year old group BMI was significantly, and negatively correlated with HDL in black and white men and in black women	Method of assessment of diet validated and reliable for white men and women, but not for blacks Multiple factor analysis across subgroups results in inconsistent and erroneous findings in subgroups.

TABLE 1.—LIPIDS AND CARDIOVASCULAR DISEASE: EPIDEMIOLOGICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Test/Methods	Results	Comments and assessment
Yamori 1989 (Ref. 146).	Cross sectional multicenter cardiac study of the relation of diet to serum lipids.	40 centers 20 countries 100 males and 100 females 50 to 54 year.	1 year	BP, clinical dietary factors CVD risk factors. Dietary: Potassium, calcium, protein.	Preliminary report of Cardia Study; specific regions in China have high BP, high salt intake (13 to 16 g/day), K and Ca intake low in China and Japan. Together high Na low K and Ca result in high BP and therefore increased risk for CVD Caucasia in USSR have low TC (172 mg/dl), high protein Cultural habits to boil meat which reduced fat and cholesterol, have low incidence of CVD in 7 community centers in Japan in which Na consumption in high have increased incidence of stroke and stomach cancer.	Lack of sufficient detail of dietary fat assessment; difficult to draw conclusions regarding dietary fat and heart disease.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Abbott 1990 (Ref. 2).	Diet Intervention, (lipoprotein metabolism, self controlled.	7 NonDiabetic (ND) 7 NIDDM, Pima Indians age ND 32 yr, 1 female age. NIDDM 39 (3 female cross over).	5–7 weeks diet 1: high fat, 5 wks. diet 2: low fat, high carbohydrate, 5 to 7 wks.	Solid food 1. High fat 42% of calories. 2. High Carbohydrate (65%), low fat (21%) of calories.	Consumption of high carbohydrate diet, by both ND/NIDDM groups, reduced LDL-C levels. Fractional clearance and total VLDL, LDL-C, and apoprotein B unchanged. Plasma VLDL TG increased by carbohydrate diet.	Since LDL-C was decreased in both ND/DIDDM by high carbohydrate, low fat diet; gives support for a general population strategy to lower serum cholesterol. Small number of subjects. Well designed study.
Baggio 1988 (Ref. 4).	Metabolic study of impact of impact of dietary fats on serum lipids (Controlled).	11 males, 20.9 aver yr. Metabolic ward	6 week 5 week/diet	Low fat diet High fat olive oil	Found decrease in TC (−9.5%), LDL-C (−12.2%) TG (−25/5%) in olive oil enriched diet; HDL unchanged; Olive oil rich in oleic acid (C18:1). Diet compliance measured: Fatty acid; profiles of RBC membranes before and after diet; olive oil used in food. High fat diets in Mediterranean countries but low CHD death rates.	Small number of subjects, well designed and well controlled for compliance.
Berns 1990 (Ref. 5).	Dietary intervention and lifestyle study. Evaluation of diet by questionaire and diet records. Subjects divided into cohorts.	315 Dutch males 28–29 yr, free-living, selected based on BMI.	2 weeks	Representative of Dutch population; fat: 39% of calories; carbohydrate: 43% of calories, cholesterol: 128 mg/kcal.	BMI, body fat, waist/hip ratio, intra-abdominal fat and alcohol positively associated with, TC, TG Alcohol (%) strongly and independently associated with TC and HDL-C.	TC levels within population very large. Actual TC range much larger within population than predicted by Keys equation.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Berry 1991 (Ref. 6).	Randomized dietary intervention (cross-over). Evaluation of diet by diet records.	26 healthy males	12 week/diet, 32 wk study.	High MUFA diet high PUFA diet (each 32% of total calories); solid foods.	Total serum cholesterol reduced by MUFA and PUFA diets: (MUFA: 9-10%; PUFA: 16%). TG and HDL unchanged by the diets. Lipid peroxidation (measured by thiobarbituric acid reactive substance activity) increased on PUFA enriched diet. Suggested that PUFA diet could cause oxidative stress. Compliance measured by RBC membrane fatty acid composition.	Well designed and conducted study. Short duration, small number of subjects, one gender. Authors suggest MUFA not only lowers TC but may reduce atherogenic potential from oxidized LDL.
Boyd 1990 (Ref. 9).	Randomized dietary intervention.	206 women >30 yrs of which >50% had mammographic dysplasia. Free-living	1 year	Test diet: Low fat diet decreased from 37% down to 21% of calories; carbohydrates increases from 44% up to 52% of total calories. Control diet: habitual diet	Low fat, high carbohydrate diet reduced serum cholesterol levels most in women who had the highest basal cholesterol levels. Results suggest that women and men respond similarly to low-fat diet.	Analyzed only one sample/interval. Suggested the use of serum cholesterol levels as a monitor for dietary compliance compared to estimates from food records. Results suggest women and men respond similarly to low fat diet.
Brinton 1990 (Ref. 11).	Self-controlled metabolic ward study of the effect of dietary lipids on lipoprotein and apoprotein metabolism.	13 (5 male & 8 female); Mean age: 24 yr; BMI: 22.9.	4 wk run-in; 2 diets; 4 wk per diet.	2 Diets 1. HSFA fat 42% of calories P/S 0.1. 2. LSFA fat 9% of calories P/S 1. Solid food diets, intake adjusted to maintain individual energy requirements.	Used radiolabeled apo I and II to measure FCR (fractional catabolic rate and TR (transport rate). Switch from HSFA to LSFA diet decreased HDL-C by 29% while apo AII did not change. FCR of APO I increased 11% and TR decreased 14%. FCR apo AII increased 5%. LPL decreased 23% HL decreased 17%. Increase in clearance of HDL and decrease in synthesis. Within each diet group HLD-C was inversely related to apo AI FCR but not apo AI TR. Diet influence apo AI TR which may account for decrease in HLD-C.	Diets were at extremes (42%) vs a very low fat diet (9%); diets were short term (2 wk); highly variable results; TR not measured direct but by formula which could lead to statistical artifact. Composition of baseline diet not specified.
Brown 1990 (Ref. 12).	Drug/diet intervention study, randomized, double blind.	120 men 62 year high risk CVD.	2.4 yr	1. Lovasatin (40 mg/d) + Colestipol (30 mg/d). 2. Niacin (4 mg/d) + Colestipol (30 mg/d). 3. Placebo or Colestipol.... All subjects on low-fat diet.	Serum lipid profiles and arteriographic analysis used to evaluate drug treatment-diet. Lovastatin + colestipol reduced LDL 46%, increased HDL 13%, progression of lesion limited to 21%, regression increased 32%. Niacin + colestipol reduced LDL 32%, increaed HDL 43% decreased progression 25%, regression increased to 39%. Diet reduced LDL 7% and increased HDL 5%. Aggressive drug intervention reduced incidence and frequency of MI by 73%.	Well designed study. Change in CHD assessed visually and quantitatively by 2 experienced blinded observers.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Buchwald 1990 (Ref. 14).	Surgical Intervention..... Randomized trial of ileal bypass surgery and serum lipids and CHD risk.	838 men/women 51 year old, high risk, MI survivors 90% men.	9.7 years.....	Ileal bypass 417 control 421 surgery.	Surgical intervention decreased TC 23%, LDL 37% and increased HDL 14.3%, decreased morbidity due to CHD (44 vs 32), reduced recurrent MI events (39 vs 24), reduced death all causes (62 vs 49). Both groups were on AHA Phase II diet.	Can not ethically have control which does not receive drug or diet to lower serum cholesterol. Good study.
Burr 1989 (Ref. 16).	Dietary intervention ..... Randomized ..... Evaluation of diet by diet questionaires.	2033 male survivors of MI; mean age 56; Wales. 4 groups; 1. reduce fat intake; 2. increase P/S ratio; 3. increase fish intake; 4. increase fibre intake	2 year.....	Experimental diets plus control. 1. Low fat (30%) ..... 2. P/S of 1.0..... 3. Fish (200–400 g) per wk. 4. Fiber (cereal) 18 g/ day.	No significant differences in fat or fiber group with respect to MI death, total mortality or reinfarction. Total mortality lower in fish group (29%) at 2 years, no difference in IHD events. Fiber group had slightly lower survival rate.	Differences between compliance to diets on fat and control group very small: both at about 32% fat ad 0.78 P/S ratio. TC fell 0.14 mmol/1 in low fat group (3 to 5%). Fiber compliance better: 19 g/day vs 9 g/day control group Difficult to control dietary intake.
Cobb 1991 (Ref. 18).	Drug and diet intervention. Randomized, double blind, crossover. Evaluation of diet by diet records. Metabolic ward.....	70 men/women, high risk hereditary and environmental factors.	3 wk/diet 10 day wash out.	High Fat diet vs Low Fat diet Lovastatin (40 mg/day) (drug).	Found no diet-drug synergism in reduction of blood cholesterol. Lovastatin reduced blood cholesterol on both low and high fat diets.	Did not do cross-overs, many patients were in advanced disease state, more patients (80%) had reduced cholesterol levels on low fat diet but had smaller reduction.
Cohen 1988 (Ref. 19).	Dietary intervention, effect of dietary fat on serum lipids, controlled.	12 healthy males, 20–25 yr old, exercised, non-smokers, normal glucose tolerance, non-obese.	3 days, nonfasted subjects.	Intake response: fat and blood lipids—test fat was cream [11% C14:0; 30% C16:0; 14% C18:0 and 27% C18:1]. Fat intake: 1. 40 g ..... 2. 80 g ..... 3. 120 g.....	Measured the effect of fat consumption on serum TG. In response: 40 g cream=251 mg/dl; 80 g cream=503 mg/dl; 120 g cream=712 mg/dl. In normal healthy males the serum TG levels were proportional to the amount of fat consumed. Maximum response to test intake was at 2 hr Test followed for 8 hr.	Well designed and executed study. Changes in serum TG varied linearly with fat content (SFA predominately) of test meal. Fat intake test within limits of how used in general population.
Curzio 1989 (Ref. 26).	Dietary intervention, randomized, free-living, diet counseling.	124 male, female 6 mo >61/gp, hypercholesterolemic hypertensive patients, age 56.5 year.	6 month.....	Low fat, high carbohydrate diet.	Compared to baseline values in 1987, both group's serum cholesterol decreased significantly. Diet intervention group decreased more in weight, TC, TG, LDL-C compared to controls. HDL-C remained unchanged.	Decrease in total cholesterol and LDL cholesterol in non-dietary group may be due to spontaneous changes in diet due to media coverage.
DeBacker 1989 (Ref. 28).	Diet, randomized..... Survey MONICA Project screening program.	134 men, 45 to 64 year, Belgium.	3 day food record.	Food consumption diary identify fatty acids, and serum lipids.	Need an objective marker to measure diet compliance within population, as well as, in individuals. Found a highly significant relationship between diet and serum CE fatty acids, but not between diet and total serum lipids.	Diet: fat 39.9%, SFA 16.6%; MUFA 14.5%, PUFA 7.1% and cholesterol 392 mg. Serum CE fatty acids: linoeate (18:2) 58%; oleate (18:1) 22%; palmitate (16:0) 13%; arachidonate (20:4) 6%.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Dreon 1990 (Ref. 37).	Diet intervention, cross-over, controlled, randomized. Diet evaluation by dietician advise and home visits.	19 males, 20 females: free-living Mormons (did not smoke, no caffeine, no alcohol, mean age 48 years).	12 wk/diet 30 wk/study 12 wk/run in.	2 Diets 1. PUFA enriched 2. MUFA enriched PUFA Saf oil MUFA O oil. Total fat 30% of calories; carbohydrate 55% of calories.	No significant change in VLDL, LDL-C, TC, HDL-C or TG due to PUFA or MUFA enriched diet. Subfraction of HDL did change HDL-2 was 50% higher and HDL-3 was slightly lower with PUFA compared to MUFA diet. APO B was 5.4% lower on PUFA diet.	Study well designed for a free living study; included eliminated many risk factor because subjects were Mormons. The authors saw no advantage of one UFA over the other with respect to total HDL-C. When subjects on low fat diet, changes in type of UFA may not alter serum-lipid levels.
Edington 1989 (Ref. 41).	Dietary intervention, crossover, free-living. Evaluation of diet by diet records.	58 men; hyperlipidemic/48 Normal chol or hyporesponders.	3 month	Low Fat diets 3 periods 1. + 410 mg chol 2. + 90 mg chol 3. +410 mg chol	Hyperesponders = those whose plasma cholesterol increased >8%; hyporesponders + those whose plasma cholesterol increased less than 5% when diet supplemented with 3 eggs. Dietary cholesterol intake has small effect on blood cholesterol when SFA intake is low; confounders with cholesterol supplements are low SFA and high fiber.	Possible application to general population ie free living and contained both hyper and hypo responder to dietary cholesterol. On low fat diet, added dietary cholesterol may not increase TC.
Frantz 1989 (Ref. 42).	Double blind, randomized trial of dietary fats, serum lipids, and CHD risk. Institutionalized Single end point	Minnesota state mental hospitals 1 nursing home 4393 men and 4664 women.	Longest on diet 4.5 yr., mean day on diet 384, 1568 on diet > 2 yr.	Diets 1. High SFA + high chol 2. Low SFA + low chol Control diet= no. 1= (18% SFA, 5% PUFA, 446 mg chol); test diet no. 2 = (9% SFA, 15% PUFA, 166 mg chol).	Diets had equivalent amounts of fat but differed in SFA, MUFA and PUFA Lower SFA, high PUFA reduced TC from 203 to 175 mg/dl. No differences were observed in MI events, CVD death or total mortality when all age groups averaged. Slight increase in death (MI) in men and women on low SFA and High PUFA diets in age 45 to 55 group but not in 35 to 39 year old group.	Patients in study (81%) in hospital <1 yr, question on outside hospital compliance. Deaths from external causes higher in patients on low SFA, high MUFA, PUFA diets. Age group differences in MI and deaths.
Friday 1991 (Ref. 43).	Dietary intervention study on metabolic ward, self-controlled, cross-over.	3 men & 2 women Familial hypercholerolemia (FH); 5 normal aver age 40.	3 wk/diet 3 wk/washout.	3 Diets, natural foods; differ in source of FAs. 1. Butter (SFA) 2. Saf oil (n-6) MUFA 3. Salmon oil (n-3) PUFA caloric intake adjusted to maintain individual energy requirement.	Normal subjects and similar reduction in TC, LDL-C as FH (heterozygous) patients. VLDL did not significantly change in normals but was reduced 44% in FH. PUFA diet reduced TC, LDL-C apo B slightly in FH patients compared to MUFA diet.	Very few subjects; may also have sex differences which mask final results. Both FH and normal controls, however, responded to diets (substitution of MUFA and PUFA for SFA) in similar fashion & therefore may have application to general population.
Fumeron 1991 (Ref. 44).	Diet intervention, crossover, randomized. Evaluation of diet by diet history.	36 healthy males average 23 yr.	3 wk/diet	2 diets Differ in source of FAs 1. 70 g Butter (SFA) 70 g control diet. 2. Sunflower oil (high PUFA) test diet.	Compared to butter diet, the sunflower oil (more PUFA) in diet reduced TC, TG, LDL-C and HDL-C. When total fat intake is high, but not excessive (even if P:S ratio is high as part of diet) there was a diminution in protective HDL and HDL-2.	Well designed study. Decrease in SFA and increasing PUFA reduced serum lipids levels (TC and LDL-C); however, also reduced HDL-C.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Ginsberg 1990 (Ref. 45).	Diet intervention, randomized, double blind, controlled. Evaluation of diet by 5 day diet record.	36 healthy, free-living, young men, 22-32 year old.	10 wk/ run in; 10 wk/ Step 1 diet; Control diet, typical American diet.	3 Diets 1. AHA Step 1 2. AHA Step 1 + 18% MUFA. 3. Amer diet AHA diet fat '30% of calories. American diet, fat '30% of calories. American diet, fat '38% of calories.	Compared two experimental diets with typical American diet effect on serum lipoprotein. Step 1 Diet reduced TC and LDL-C significantly, while TG and HLD did not change. Step 1 diet with additional MUFA (not substituted for SFA) did not significantly increase beneficial effects of Step 1 diet.	Large degree of variability in results; would have been better to use cross over design and subjects serves as own control. Carefully analyzed study. Dietary compliance stated as 85% in free living subjects, difficult to assess.
Grundy 1988a (Ref. 53).	Diet intervention; reanalysis retrospective, random.	10 to 17 men/study 4 studies patients high to normal TG and cholesterol.	6 wk/diet	4 Liquid diets 1. linoleic vs lard 2. linoleic vs palm oil 3. oleic vs palm 4. oleic vs coconut oil	Summarized 4 studies: response to SFA is highly variable. SFA was not provided from a single type of fat. Source of SFA important "If it can be shown that people with higher cholesterol levels are more responsive to SFA than those with lower levels; this would add support to the high risk strategy in causation of primary hypercholestolemia".	Small number of subjects; well designed.
Grundy 1988b (Ref. 54).	Diet intervention; metabolic ward crossover 1 month run in order diet random.	10 healthy men mean age 64 6/10 smokers.	6 wk/diet	3 Solid Food diets 1. high SFA vs high cholesterol. 2. high MUFA vs low cholesterol. 3. high carbo vs low fat	High MUFA-Low chol and low fat diet both reduced total serum chol (32 mg/dl) and LDL-C equally effectively when compared to high SFA-high col diet. Low fat diet also reduced HDL-C 6 mg/dl compared to High chol-MUFA diet. Low fat diet AHA Phase III.	Small number of subjects, smoking confounder.
Hayes 1991 (Ref. 59).	Diet intervention, crossover, random.	Non-human primates; 3 species. 8 animals /species, 10-15 yr old.	12 week per diet.	5 diets isocaloric Fat 31% of calories, diets differ in P/S ratio (range 0.1 and 1.0).	When 16:0 replaced 12:0 and 14:0 there was a significant decrease in TC and LDL-C. When 16:0 replaced 18:2 however, there was a slight increase in TC and LDL-C. 18:1 was weakly hypocholesterolemic. Plasma cholesterol in all three species affected in same direction (high P/S, lower TC) but the magnitude of the shift varied. Cebus monkey were most responsive, dropping 2.5 mmol/l TC when diet P/S ratio went from 0.12 to 1.04. Rhesus monkey was least responsive, therefore, resistant to hypercholesterolemic effect of 12:0 and 14 0.	Well designed study. Impact of any given dietary fatty acid depends upon chain length, relative saturation and relative concentration of all fatty acids available (diet, storage, part of active metabolic fats).

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Hudgins 1991 (Ref. 64).	Clinical study of trans-fatty acid intake and adipose tissue storage, randomized.	76 healthy males aver age 46.8 yr free living.	N/A	Gluteal adipose tissue fats; clinical lipids. isomeric forms of fatty acids.	Dietary *trans*-fatty acid of 18:1 and 18:2 concentrate in adipose tissue. Found no strong assoc between CVD risk factors and conc of *trans*-fatty acids in adipose. Autopsy data show however, show slight + correlation of *trans*-fatty acid with hyperlipidemia.	Careful study Possible negative correlation of consumption of *trans*-fatty acids and risk of CVD.
Johnson 1990 (Ref. 66).	Clinical trial of effect of dietary cholesterol on serum lipids. Cross-over, blinded, randomized.	10 healthy, free-living males, normal lipidemic, age 27 yr athletic.	4 wk/diet	Two Diets 1. 200 mg chol 2. 600 mg chol 30% fat, 55% carbohydrate chol ' eggs natural food.	High cholesterol diet increased LDL-C and apo 8 (10 and 13% respectively) in healthy males. High cholesterol diet did not change TG, HDL-2 and HDL-3 significantly. Individual responses were highly variable. Three subjects had LDL increases >25%, 2 increased between 10-25%.	Well designed study. Small no. of subjects. Importance of exercise—25 minutes aerobic exercise per day, did not prevent the cholesterol raising effect of dietary cholesterol. Dietary restriction may, therefore be justifiable even on low fat diet with exercise. Response to dietary cholesterol highly variable.
Katan 1988 (Ref. 67).	Clinical trial of effect of dietary saturated FA and cholesterol on serum lipids. Controlled, cross-over.	24/group, men and women; age 28 to 54 previously identified as hyper-responders to cholesterol:. Normal Egg eaters, Not defined what is normal egg or what HAb egg eaters consumption not defined,.	3 wk/diet	Two Diets Regimens 1. Norm-Egg 21% PUFA, 11% SFA (high P/S). 2. HAB-EGG 5% PUFA, 23% SFA, (low P/S).	Question raised was do individuals who are hyperresponders to dietary cholesterol, also hyperresponders to SFA. On both diet regimens, HDL and TC increased on SFA diets and decreased on PUFA rich diets in Normal group, those who responded to increased dietary cholesterol also responded to SFA In habitual egg group, however, this was not true. Suggested that there are persons in the normal population who are both hyperresponders to dietary cholesterol and SFA Chronic egg consumption may change metabolism Dietary membranes—especially linoleic/oleic acid ratios.	Subjects in Habitual egg group were older than normal group. Small number subjects, diet short term. The authors suggest response to both dietary SFA and cholesterol congruent.
Kestin 1989 (Ref. 69).	Clinical trial of effect of fats on serum lipids. Cross-over, randomized. Evaluation of diet by dietary records and diet analysis (Each subject completed 2 diets out of 6 possible combinations).	26 healthy men average age 44.	6 week/diet	3 Fat modified Diets 1. High fat (HF)=(AUS) 2. Lacto-ovo-vegetarian (LOV). 3. Lean meat-LM	LOV and LM diets decreased BP, TC, LDL-C compared to high fat (42%) AUS diet. Both LOV and LM diets increased TG C12:0, C14:0, and C16:0 higher in AUS HF diet by minimum of 2x than LOV or LM diets. Protein source raised as possible influence on chol; wheat protein in diets LOV and LM not soy; wheat contains enriched amounts of glutamate, which may be hypocholeste olemic.	Well designed study. LM and LOV diets have similar effects on serum lipids. Compared to diet high in SFA both LM and LOV diet will reduce serum lipids. Source of protein may be important determining serum lipid levels.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Leren 1989 (Ref. 76).	Diet intervention, effect of dietary fat on CHD risk on those with and without previous MIs.	412 men, 30–64 yr who had MIs in 1956–58; half serve as control Oslo. 1232 nonhypertensive, high risk CHD age 40–49 in 1972–73.	5, 8.5, 11 yr	Low fat diet. Fat 39% of cal, 21% SFA, 26% MUFA, 53% PUFA. Control habitual diet. Fat 40–50% of cal., primarily SFA.	Results of secondary trial: after 5 years diet intervention group has fewer recurrent MI and fatal MI than control: Diet—43 MI/34 patients Control 64 MI/54 patients. After 11 years CHD death in Diet group was 79 and 94 in controls. In the Primary trial: measured at 5 and 8.5 years high risk CHD males which had no previous MI results showed dietary intervention reduced MI death nonfatal MI by approximately half MI death 6 diet group and 14 in control; non fatal MI 13 in diet group and 22 in control. Same trend at 8.5 years ...	Estimates of recurrence of MI from secondary trial (already had MI) in those on low fat diet compared to habitual diet.
Lopes 1990 (Ref. 82).	Observational study of effects of FA intakes on serum FA. Evaluation of diet by food frequency questionnaire.	12 male/female aver age 34 yr.	22 month	Diet fatty acids compared to plasma FA in TG, PL, FFA, CE over time.	Fatty acids found in plasma in greatest abundance: 16:0-palmitic; 16:1-palmitoleic; 18:0 stearic; 18:1 oleic; 18:2-linoleic, 20:4-arachidonic. Diets vs TG–FA were most strongly correlated in men, No strong correlation between diet vs TG–FA in women; but did in FFA (18:1). Sexual difference in FA: CE:FA 20:4 male>female; PL–FA 20:4 male>female; TG–FA male 2x>than female. Fatty acid most strongly correlated with ethanol intake 16:1.	Small number of subjects and is the food frequency questionnaire adequate record of dietary intake.
Luria 1991 (Ref. 84).	Clinical study of relationship of serum lipids to extent of athersclerosis.	380 high risk men/ women average 59.	7.5 yr	Serum lipids, and rheologic arteriographic. Pathological analysis and risk factor clustering.	Ratio TC/HDL–C closely related to presence—extent of coronary artery reduction. Divided into quartiles of highest or lowest risk. Suggested ratio is a marker for clustering of potential risk factors.	Well designed and executed study. High levels TC and low levels HDL correlated with size of coronary obstruction (reduction). An increase in the number of risk factors, the greater the risk of CVD.
Mannien 1990 (Ref. 85).	Dietary trial demonstrating effect of reduced serum lipids on CHD. Randomized, placebo control.	2590, Fredrickson Type IIa men; average age 50.	5 year	Gemfibrozil	Two independent variables and one is neg and one pos; difficult to predict disease outcome. Gemfibrozil raised HDL–C while lowering LDL–C. With similar LDL–C levels; those with higher HDL–C have 5x less risk of CAD. Drugs more effective against highest risk groups.	Well designed study. Medical intervention which reduces LDL–C and increase HDL–C decreases CVD risk significantly.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Manttari 1991 (Ref. 86).	Diet/drug intervention study of effect of reduced serum on apoproteins. Randomized, double blind. Evaluation of diet by diet interviews.	230 Finnish men high risk CHD half had MI during study.	15 month, part of the Helsinki Heart Study.	Gemfibrozil 600 mg 2x day; placebo low fat—low chol diet all subjects. Habitual diet; fat=37-40% of total calories. Diet intervention: fat=30-35% of total calories.	Subjects at baseline chosen to have similar TC and LDL-C levels, all were dysplipidemic. Out of 230 subjects 96 expressed E4 and 171 expressed E3 phenotype or in other words, 151 did not carry E4 allele. Those with dietary counseling, who expressed apo E4 allele, had the largest reduction in TC and LDL-C. For those who were treated with gemfibrozil, the same reduction in TC and LDL-C occurred with and without apo E4 allele.	Did not record SFA or cholesterol content at baseline or during the study, therefore, cannot relate specific fat with apo E regulation. Excellent laboratory analysis of apo E and possible clinical applications.
Marzuki 1991 (Ref. 88).	Observational study comparing effects of two types of dietary fats on serum lipids. Residential, self-controlled, run in/wash out diets used.	110 healthy Malay males, age 16.5 year Malaysian diet.	6 wk/diet	Solid food cooked in: 1. Palm olein 2. Soybean oil fat 35% of total calories.	Regardless of cooking oil used (Palm or Soy) plasma chol and lipid profiles were unaltered Palm oil rich in 16:0 and 18:1 while Soy rich in 18:2 fatty acids.	All subjects were healthy young men, consuming native diet, with no other risk factors for CAD.
McDonald 1989 (Ref. 89).	Clinical study of effects on specific fats on serum lipids. Cross-over, self-controlled. Diet evaluation by diet analysis.	8 healthy males, age 19 to 32 yr.	48 days 18 days/diet	Solid food 1. Canola (>MUFA) 2. Sunflower (>PUFA) fat 36% of calories. Canola = 59% oleic Sunflower = 73% linoleic. CanSun diet vs SunCan diet.	Canola oil rich in 18:1 while Sunflower oil rich in 18:2. Both CANSUN and SUN-CAN regiment reduced total chol; but SUN-CAN lower chol > than CAN-SUN. Neither oil altered HDL-C. Canola increased prostacyclin > than SUN. Thromboxane B-2 decreased by CAN and SUN compared to mixed fat diet CAN prolonged obstruction time.	Unlike other studies linoleic acid (18:2-SUN-PUFA) did not decrease HDL-C. Like other studies, oleic acid (MUFA) lowered TC without lowering HDL-C. Well designed study.
Mendis 1990 (Ref. 92).	Clinical study of effects of specific fats on serum lipids. Cross-over, wash out 3 wk.	25 normolipidaemic males 20-26 yr. Sri Lankan prison	8 wk/diet	Two Diets differ in P/S ratio. 1. P/S = 4 2. P/S = 0.25 Fat soya-bean and coconut oil.	Compared to baseline soya-bean diet reduced TC, LDL-C, TG and HDL significantly. Coconut diet increased TC. Normal Sri Lankan diet is 27% fat, high carbohydrate. The fat of Sri Lankan diet is primarily SFA derived from coconut oils.	Well designed and executed study. Another study that shows reduction in dietary SFA reduces TC and LDL-C.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Mensink 1989a (Ref. 93).	Clinical study of effects of specific fats on serum lipids. Randomized, controlled, diet run-in 17 days, inst food.	58 Dutch men and women 19–48 years healthy 29/gp.	36 day/test diet, 17 day run-in on high SFA diet.	Control diet: SFA 19% of energy, MUFA 11.5%; PUFA 4.6%. Test diet 1. MUFA rich, SFA 12.9%; MUFA 15.1%; PUFA 7.9%. 2. PUFA rich SFA 12.6%; MUFA 10.8%; PUFA 12.7% caloric intake adjusted to maintain energy requirements.	Compared to control diet MUFA enriched diet decreased TC and LDL-C, apo B slightly more than PUFA enriched diet in both men and women. Both test diets had lower SFA content than control diet. Test diets had a mixture of MUFA and PUFA, which in the specific test diet was enriched. Both test diets reduced HDL-C (PUFA>MUFA) was more in men than women.	Compliance determined by fatty acid content in serum CE. Individuals on MUFA diet had more oleic acid in CE and those on PUFA had more linoleic in CE. MUFA enriched diet as effective or better than PUFA enriched diet in lowering serum cholesterol. Several subject had influenza like symptoms concomitantly with decreased HDL-C. Well designed and executed study.
Mensink 1989b (Ref. 94).	Clinical study of effects of specific fats on serum lipids. Diet run-in, controlled.	48 healthy adult men/women, Dutch and 76, 8 to 10 years old Cretes.	36 day/test diet 17 day run in on high SFA diet.	Diets 1. Control diet high SFA 20%, 38% total fat; 47% Carbo. 2. High Carbo 62%; low fat 22%; SFA 6.7%. 3. Olive oil fat 40.6%, SFA 9.8%, MUFA 24% carbo 46%.	Results from clinical study compared to Crete boys diet and serum lipids. Dutch study: TC decreased 0.44 mmol/1 on high carbohydrate diet and 0.46 mmol/1 on olive oil diet HDL-C fell on high carbohydrate diet 0.19 mmol/1 and increased on olive oil diet (0.03 mmol/1). Epi study and clinical study did not agree on effect of olive oil diet on serum lipids.	Compared 8 to 10 year old boys in Crete with adult men/women in Holland. Used pooled blood samples to analyze lipoprotein profile in Crete boys. Food intake examined on two consecutive days. Study tried to compare to many subgroups and cross study design types. Compares apples and oranges.
Mensink 1990 (Ref. 95).	Clinical study of effect of specific fats on serum lipids. Cross-over, randomized, controlled, no wash out.	34 women 25 men average age 25 healthy 8 women on oral contraceptives.	3 week/diet	3 Diets Diets differ fatty acids (10%). 1. oleic, cis 2. elaidic, trans 3. SFA, 12:0, 16:0	Diet were identical, varied only 10% fatty acid as either. 1. oleic, cis; 2. elaidic trans or 3. SFA lauric and palmitic. Compared to oleic acid, *trans* form increased LDL-C significantly (14 mg/dl) and decreased HDL-C by 7 mg/dl. SFA increased LDL-C (18 mg/dl) but HDL-C was unchanged.	Excellent well designed and executed study, well controlled. *Trans*-F.A. could increase risk CVD at higher levels than currently consumed. *Trans*-fatty acid not only raised LDL-C but lowered HDL-C as well. The concentration of *trans*-fatty acid used was higher than current availability data in US population.
Miettinen 1989 (Ref. 96).	Clinical of effect of dietary cholesterol on cholesterol metabolism. Cohort evaluation of clinical results with dietary intake, randomized diet. Evaluation of diet by dietary records.	63, 51 year old males, normal, free living, random selection.	>1 week	0.14, uCi Chol; 0.28, uCi B-Sitosterol; 200 mg Cr203. Cholesterol: 487 mg/day Fat: 108 g/day Habitual diet	Cholesterol absorption efficiency reduced by obesity. Absorption of dietary chol increased with intake. The more fractional and absolute chol absorbed; the more chol synthesis inhibited. 1 mg.kg/day chol=decrease 2.2 mg.kg/day of chol synthesis. The higher the synthesis of biliary chol the lower the absorption of dietary chol. Plant sterol reduced fractional chol absorption; enhanced fecal chol elimination.	Well designed study. The authors conclude that the amount of chol absorbed may regulate both chol synthesis and elimination in some individuals more than others.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
MRFIT Research Group 1990 (Ref. 101).	Community trial of diet and lifestyle intervention on serum lipids and CHD risk. Randomized, controlled. Special Intervention (SI).	12,866 CHD high risk men, 35 to 57 years.	10.4 years.....	SI..... 1. Diet low fat, chol..... 2. Smoking..... 3. Drug for hypertension...	Intervention group had lower mortality at 10.5 yrs from all causes (−7.75), CHD (−10.6%) and CVD (−8.3%). There was a 24% reduction in death due to acute MI in special intervention (SI) group. Risk factors for CHD declined in both groups. SI group had increase in death related to respiratory and intrathoracic organs (+20.1) and digestive system (+36.8%). Used blood pressure reducing drug: chlorthalidone and hydrochlorothiazide.	Well designed and executed study. The more risk factors reduced, the greater reduction of CVD risk.
Nervi 1989 (Ref. 102).	Clinical study of effect of high carbohydrate diet on serum lipids and gallstones. Institutional food consumed 6 days/week.	20 (18–22 year) healthy men Chilean.	1 month/diet.....	Two diet regiments..... 120 g/day legumes vs isocaloric no legumes.	Legume diet compared to control diet: decreased LDL-C, HDL-C, increased biliary cholesterol saturation in 19 out of 20 subjects by at least 50%. Legume consumption suggested as a risk factor for cholesterol gallstone. Biliary total lipids concentration same however, PL concentration down and cholesterol and bile salts up.	Well designed and executed study. An 8% amino acid solution was used to stimulate gallbladder contraction; different legumes used have variable concentration of possible active components, such as saponin.
Ng 1991 (Ref. 103)	Clinical trial of effect of types of FAs on serum lips. Randomized, cross-over, double blind. Evaluation of diet by diet records (food provided).	123, Malay men (61) and women, age 24 random assigned to 3 test groups.	5 wk/ test diet.... 15 wk/study.....	3 diet regiments..... 1. Coco-palm-coco..... 2. Coco-corn-coco..... 3. Coconut solid food cooked in oils.	Diet fat was 32% of total calories. The oil provided 75% of the total fat. Coconut oil raised chol 10%. Palm olein and corn oil reduced chol (−19 and 36%), reduced LDL-C ad HDL-C. Corn oil reduced TC, LDL-C and HDL-C more than palm olein. Corn oil hypotriglyceridemic.	Over simplification to judge an oil solely on basis of SFA content. No dietary baseline data provided, actual intakes, changes in body wt, adjustment for confounders not reported.
O'Dea 1990 (Ref. 105).	Clinical study of effect of dietary fats on serum lipids. Controlled..... Evaluation of diet by diet records.	10 healthy men/women, average 25.2 yr.	5 wk/study run in 1 wk.	Very low fat [fat-lean meat] vs added beef fat to very low fat=8% high fat=20–30%.	Within 1 week on extreme low fat diet, total chol dropped 9%, LDL-C dropped significantly and HDL-C dropped but not significantly TG increased significantly on low fat diet. Beef fat, not beef meat, identified as dietary risk factor in raising blood chol. Beef fat 20 and 30% of total calories raised blood cholesterol. The higher the P:S ratio the more the HDL falls along with LDL-C. Diets, not excessively low in SFA nor increasing in PUFA do not generally raise HDL-C levels.	Small number of subjects. Short run in for diet. Study results indicate that it is the fat from beef that increases serum cholesterol and not the beef.

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Ornish 199 (Ref. 106).	Clinical trial of effect of diet and lifestyle on serum lipids and atherosclerosis. Prospective, controlled.	48 high risk CHD, free-living men, 5 women; age 56 year (expt) 50 year (control) have atherosclerosis. Coronary arteries assessed at baseline and after 1 yr.	1 year	Diet Intervention 1. Low fat veg diet non-smoking stress management moderate exercise. 2. Usual Care	Short term life style intervention (1 year) reduced the diameter of the stenosis in patients with atherosclerosis and appeared to reduce the progression of the disease. TC, LDL-C reduced, HDL-C unchanged, TG elevated in intervention group. Fat intake reduced to 6.8% of total calories in intervention group compared to 30% in cholesterol.	Well designed and executed study. Results suggest that low fat, vegetarian diet reduced the profession (or regression) of atherosclerotic placque.
Rifail 199 (Ref. 111).	Clinical study of effect of amounts of fat in test meal on serum lipids. Method(s) compared to calculated values.	16, healthy males, 23–34 yr non smokers postprandial effects.	8 hour	High fat test meal, 70 gm fat, 580 mg chol, 1110 calories: 56% fat.	A single high fat meal increased TG and VLDL. Maximum response to test meal at 3 hr HDL's Apo A's and apo B were not altered by fat meal by 8 hr. Differences between measured directly (LRC Method) versus. Calculated values by Friedwald equation. If patient not fasted, the LDL-C concentration will be significantly underestimate. To minimize postprandial effect on plasma lipoprotein, a minimum of 8 hr fat is required for accurate measurement of VLDL. TC, HDL's, apo A and B can be determined adequately using non fasting serum.	Short time, small number subjects. Results should be considered when cross comparing design and results from different laboratories.
Sorci-Thomas 1989 (Ref. 127).	Animal study of effect of diet on serum lipids. Mechanism, dietary intervention.	25 adult male African green monkeys.	1 year, 5 yr form most animals (male).	4 Diet Regiments Low Chol + high PUFA. Low Chol + Low PUFA..... High Chol + high PUFA... Low Chol + Low PUFA..... Chol 0.03 or 0.8 mg/kcal P/S ratio, 0.3 or 2.2.	Diet high in chol., generally increased TC, LDL-C and apo B. PUFA enriched diet reduced TC, HDL-C and plasma apo A-1 in monkeys fed high cholesterol diet by 13, 28 and 16% respectively. PUFA also decreased rate of A-1 production in the liver but not in the intestine. Effect of PUFA on apo A-1 synthesis was tissue specific.	Well designed and executed study. Monkeys respond to dietary changes in a manner similar to humans. Dietary effect of PUFA on synthesis of CHD protective factor. PUFA reduced the synthesis of apo A-1 and therefore could increase CHD risk (mechanism).
Ikkanen 1990 (Ref. 138).	Clinical trial of amount and type of dietary fats on serum lipids and apoproteins. Dietary intervention apo E phenotype.	110 North Karelian (Finland) 30–50 y.o. 56 men and 54 women healthy fresh blood.	6 wk/diet, and 12 wk/diet, with 5 wk/ switch back.	Test diet Diet 1. Low fat, P/S = 1.. Diet 2. Low fat low salt, P/S 0.4. Baseline diet, high SFA high chol.	Plasma chol correlated inversely with apo E 3/4 isoforms. Highest plasma chol found in apo E4/4. Subjects with apo E3/2 has lowest plasma chol. Association weaker on low fat , low chol diet. Greatest reduction in TC in apo E4/4. When diet switched back, these subjects had highest increase in TC.	Excellent study; The apo E phenotype may in part, determine the amount or response to dietary fat and chol which results in alteration of serum lipids levels. An apo E allele sum of 7 or more are greatest risk and most responsive to dietary lipids (mechanism).

TABLE 2.—LIPIDS AND CARDIOVASCULAR DISEASE: CLINICAL STUDIES (SCIENCE SUMMARY UPDATE)—Continued

Reference	Study design	Study population	Duration	Method/test/dose	Results	Assessment/comments
Wardlaw 1990 (Ref. 144).	Clinical study of effect of types of dietary fat on serum lipids. Double blinded, randomized, cross-over.	20 men, average 34.7 yr normal diet fat 37–43% calories.	5 week diet phase; 7 wk/ washout; cross-over and repeat.	Diets..... 1. Butter—2 wk..... 2. Corn-PUFA..... 3. Sun-MUFA	Both vegetable oil diets (PUFA and MUFA) reduced chol 16–21%, LDL-C 21–26% and TG by 10–21% compared to butter diet. Serum chol falls within 1 wk on vegetable oil diets. Dietary chol raised from 190 to 500 mg/day while on vegetable oil diet did not change serum TC, LDL-C, HDL-C or TG. High Concentration of PUFA may have pharmacological effects on lowering HDL-C, however, diets containing 35% of calories from fat and P-S ratio < 1.5 are not likely to lower HDL significantly.	Well designed and executed study. Applicable to men who consume high SFA diet (did not include women). Consumption of low fat diet reduced serum lipids levels in young healthy men who had previously consumed high fat diet. Furthermore the authors suggest some risk may be involved as reduce SFA in diet, especially substitute PUFA for MUFA.
Wood 1991 (Ref. 145).	Clinical study of effect of diet and exercise on serum lipids. Randomized, controlled. Evaluation of diet and activity by clinical activity logs, 7 day diet records, and telephone interviews.	Moderately overweight, sedentary men and women (132 each), 25 to 49 yr old; 119 men & 112 women completed study; non-smokers, low alcoholic consumption.	1 year.....	Divided into 3 cohorts 44 men & 44 women in each cohort. 1. Control, habitual diet..... 2. Hypocaloric NCEP diet. 3. Hypocaloric NCEP diet (+) exercise.	Both NCEP groups reduced body fat significantly and BP. In men: Diet (+) exercise increased HDL, while decreasing TG, apo B HDL increased significantly (13%) in men who exercised over diet alone. In women: Diet alone & (+) exercise significantly reduced BP, TC, apo B compared to controls. Women in diet alone group, had significantly lower HDL-2 and apo A-1 compared to control. Addition of exercise decreased the reduction of HDL-2 by low fat diet.	Well designed and well executed study. Suggests multifactorial approach for reduction CVD. Exercise is important in increasing level HDL. Diet is important in reduction of TC and LDL-C.

BILLING CODE 4160-01-M

21 CFR Part 101

[Docket No. 91N-0097]

RIN 0905-AD08

Food Labeling: Health Messages; Dietary Lipids and Cancer

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to authorize health claims on foods and food labeling that state that diets low in total fat may reduce the risk of some types of cancer, particularly colon, breast, and prostate, in the general population. The agency reviewed this topic under the provisions of the Nutrition Labeling and Education Act of 1990. The agency's conclusion is based on its review of the publicly available scientific literature. The strength and consistency of the scientific data supports such claims. Under this proposal, it also may not imply any particular degree of risk reduction. The proposed rule requires that to bear such a claim, the food or food product must meet the criteria proposed in § 101.62 for a "low fat" claim. FDA is proposing to permit foods that qualify to use a combined cancer-cardiovascular disease label statement and is requesting comments addressing scientific and compliance issues that may arise from the use of such combined health claims.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based on this proposal become effective 6 months following its publication in accordance with requirements of the Nutrition Labeling and Education Act of 1990.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville. MD 20857.

FOR FURTHER INFORMATION CONTACT: He-Chong C. Lee, Center for Food Safety and Applied Nutrition (HFF-265), Food and Drug Administration, 200 C St. SW Washington, DC 20204, 202-485-0358

SUPPLEMENTARY INFORMATION:

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the Nutrition Labeling and Education Act of 1990 (Pub L. 101–535) (the 1990 amendments), which amends the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary) (and by delegation FDA) to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this issue of the **Federal Register** is a proposed rule entitled "Food Labeling: General Requirements for Health Claims for Food," which establishes general requirements for health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs, and other nutritional substances (referred to generally as "substances") to a disease or health-related condition on food labels and in labeling. In that companion document, FDA tentatively determined that such claims would only be justified for substances in dietary supplements as well as in conventional foods if the agency determines, based on all of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

Sections 3(b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x) of the 1990 amendments require that within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act, and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including fats and cancer, meet the requirements of the act. In this document, the agency will consider whether a claim on food or food products, including conventional foods and dietary supplements, on the relationship between fats and cancer would be justified under the standard proposed in the companion document on general requirements for health claims.

B. Public Health Aspects

1. Prevalence and Economic Impact

The importance of cancer as a public health problem in the United States cannot be disputed. All forms of cancer taken together are ranked as the second leading cause of death in the United States and account for one in five deaths. Deaths due to cancer numbered more than 475,000 in 1987. The overall economic cost of cancer, including the direct health care costs and losses due to morbidity and mortality, was estimated to be $72.5 billion. The social impact of cancer can be measured in part by the potential years of life lost by death before age 65. Potential years of life lost were 18 million years for cancer compared to 15 million years for heart disease (Ref. 1).

Risk of occurrence differs markedly for various types of cancer. In 1990, the leading types of cancer in men in the U.S. were lung (35 percent of all cancer deaths), colorectal (11 percent), and prostate cancer (11 percent). For women, the leading types were lung (21 percent), breast (18 percent), and colorectal cancer (13 percent) (Ref. 1).

2. Dietary Lipids in the United States

Lipids (fat and oils) with dietary importance include fatty acids, phospholipids, and cholesterol. As dietary components, lipids are commonly referred to as "fats." Henceforth, the colloquial term, "fat" will be used in place of the more technically correct term "lipids."

The fatty acid components of fat are classified as short chain (less than 6 carbons), medium-chain (6 to 10 carbons), or long-chain (12 or more carbons). Fatty acids are also classified as saturated (lacking double bonds), monounsaturated (containing a single double bond), or polyunsaturated (containing more than one double bond). The polyunsaturated fatty acids are subdivided into those whose first double bond occurs either three carbon atoms from the methyl carbon (omega-3) or six carbon atoms from the methyl carbon (omega-6).

Dietary fats serve several major physiological functions, and only a brief overview will be given here. Fats facilitate the intestinal absorption of the fat-soluble vitamins. Small amounts of linoleic and linolenic acid, two polyunsaturated fatty acids, are essential in the diet as precursors of eicosanoids and phospholipids. Phospholipids, as well as cholesterol, are major components of all cell membranes and myelin, the coating around nerve fibers. Cholesterol is also the precursor of the steroid hormones and of bile acids.

Fat is the most concentrated source of dietary energy of all the nutrients, supplying nine calories per gram (g) as compared to four calories per g from either carbohydrate or protein. More than one-third of the calories consumed by most people in the United States are provided by fat. In 1985, estimated average intake of fat was as follows: 19 to 50 year old men, 36 percent; 19 to 50 year old women, 37 percent; 1 to 5 year old children, 34 percent of energy (calorie) intake. The largest contributors to total fat intake for all sex and age groups were meat, poultry, and fish as well as grain-products (including baked goods and cakes) and dairy products. For adults, meat, poultry, and fish contributed 32 to 38 percent of total fat intake, grain products contributed 19 to 22 percent, and dairy products contributed 13 to 15 percent. For children, from 1 to 5 years, dairy products (28 percent) was the largest contributor to total fat, while meat, poultry, and fish contributed 22 percent and grain products contributed 24 percent (Ref. 2).

3. Relation of Dietary Fats to Cancer

Fat consumption in the United States is in excess of that needed to meet the physiological needs for energy and essential fatty acids. Recent U.S. Government nutrition guidelines and goals recommend an American diet with lower fat (30 percent or fewer of the calories), saturated fat (10 percent or fewer of the calories), and cholesterol (less than 300 milligrams (mg) daily). The available evidence shows that this excess intake of fat has significant consequences for the American population. While the most convincing evidence supports a relationship between dietary fat intake and the risk of cardiovascular disease, high fat diets also appear to be linked to increased risk of some types of cancer and obesity A recent National Research Council's (NRC's) Report, "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 3) concluded that although there was less persuasive evidence for the relationship between fat and cancer as compared to fat and cardiovascular disease, the weight of evidence from epidemiologic and experimental animal studies suggested that dietary fat may influence the risk of some types of cancer, particularly cancer of the breast, colon, and prostate and possibly the pancreas, endometrium, and ovary. Although the

precise quantification and the nature of the association between dietary fat and the overall risk of cancer has not been determined, all recent general dietary guidelines from the Federal Government and the NRC have recommended that lower fat intakes should be encouraged in the United States (Ref. 1, pp. 119–120).

C. Dietary Fat: Regulatory History

Because there was a lack of agreement on the relationship between fat and cholesterol and good health when the agency's current regulations were adopted, FDA limited the amount of information that could be provided on the food label about these food components. Current relevant regulations are § 101.9(c)(6) (21 CFR 101.9(c)(6)), which requires that the fat content of a food be included in the nutrition label (38 FR 2132, January 19, 1973; and amended at 38 FR 6951, March 14, 1973), and § 101.25 (21 CFR 101.25) (42 FR 14302, March 15, 1977), which provides for the voluntary listing of cholesterol and fatty acid content as part of the food's nutrition label. No other information on fat or cholesterol content is permitted.

In 1986, however, with the emergence of a consensus that limiting dietary cholesterol would contribute to good health, FDA published a proposal to define terms that describe the cholesterol content of foods (51 FR 42584, November 25, 1986) and also proposed to require that, whenever these or other terms describing cholesterol content are used on the label, the fatty acid content of the food must be declared on the nutrition label.

As part of the Secretary's food labeling initiative, FDA issued a tentative final rule on cholesterol labeling in the **Federal Register** of July 19, 1990 (55 FR 29456). In that document, the agency proposed to limit the fat and saturated fatty acid content of foods bearing cholesterol claims. FDA proposed to limit the use of "cholesterol free" and "low cholesterol" to foods which, in addition to containing the requisite cholesterol levels, contain not more than 5 g of fat and not more than 2 g of saturated fats per serving. On a dry weight basis, these foods could contain not more than 20 percent fat and not more than 6 percent saturated fat.

For a complete description of FDA's regulation of the fat and saturated fat content of foods, see the proposal on fat, saturated fat, and cholesterol descriptors published elsewhere in this issue of the **Federal Register**.

In response to industry initiatives in which health messages about the relationship of low fat diets to reduced risk of cancer were placed on labels of breakfast cereals, FDA proposed to define health messages on August 4, 1987 (52 FR 28843). In that proposal, a "health message" was described as a claim for a food that addressed the relationship between that food in a diet and health. That relationship included the linkage between certain health problems (e.g., heart disease) and certain food factors and dietary habits. Because of a number of comments suggesting that this proposal was vague and unworkable, after seeking comments in an advanced notice of proposed rule making on August 8, of 1989 (54 FR 32610), FDA published a reproposal for regulating health messages in February 13, 1990 (55 FR 5176). In that document, the agency stated that it intended to review available scientific evidence to address whether a claim may be made with respect to a number of different topic areas, including fats and cancer.

On November 8, 1990, as stated above, the 1990 amendments were enacted, and FDA was charged with reviewing 10 topic areas. This document presents the results of FDA's review of the relationship between dietary fats and cancer.

D. Evidence Considered in Reaching the Decision

The agency has reviewed all relevant scientific evidence on fat and its relationship to cancer. The scientific evidence reviewed included all conclusions reached in: "The Surgeon General's Report on Nutrition and Health" (Ref. 4) and the U.S. Department of Agriculture (USDA) and U.S. Department of Health and Human Services (DHHS) report "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 6). It also considered documents from other recognized and scientific bodies, including: NRC's "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 3); NRC's "Recommended Dietary Allowances" (Ref. 5); The World Health Organizations (WHO), "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 7); and the Life Sciences Research Office (LSRO) report "The Role of Dietary Lipids in Cancer" (Ref. 8). FDA relied on these reports for a review of all evidence available before 1988.

The agency updated the conclusions reached by these reports by reviewing all human and animal studies released since these documents were completed.

To ensure that its review of relevant evidence was complete, FDA requested, in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas identified in section 3(b)(1)(A) of the 1990 amendments. The topic of fat and cancer was among the 10 subjects on which the agency requested information.

E. Comments Received in Response to FDA Request for Scientific Data and Information

In response to the March 28, 1991 **Federal Register** request for scientific data and information on fats and cancer, FDA received 15 comments from the food and dietary supplement industries, a consumer advocacy organization, trade associations, a state health department, the Government of Canada, a private nutrition research foundation, an organization of public health professionals, and a consumer.

The comments dealt with the issues of fat and cancer and related food label requirements, as well as the general goals and requirements of the 1990 amendments. FDA reviewed all of the documents including letters, press releases, scientific articles, review articles, and recommendations included in submissions. FDA included the data submitted in scientific articles in its review of scientific literature which is discussed below.

The comments received from the food industry, the private nutrition research foundation, the consumer advocacy organization, and the consumer suggested that there was adequate scientific evidence and scientific agreement to justify claims for fat and cancer. The comments from the dietary supplement trade association and nutritional supplement manufacturers stated that the conclusions in several authoritative documents filed in the FDA docket on this topic are negative with respect to the role of nutritional supplements in providing the protective nutrients that are associated with disease. The dietary supplement trade association suggested that FDA exercise its independent judgment in reviewing the evidence on nutrient-disease relationships and not rely solely on conclusions drawn in the authoritative documents.

Comments from a state health department and an organization of professional public health nutritionists recommended caution in approving health claims and the need to prevent possible abuse of health claims or misinterpretation by the general public. These comments also expressed concern about the many topics that are candidates for health claims under the 1990 amendments.

A comment from a major grain food manufacturer suggested that one of the requirements for a fat and cancer health

claim should be that the food product contains a minimum amount of dietary fiber and a standard level of all other important nutrients commonly found in that food. Criteria for qualifying levels for fat were suggested as 10 percent of calories from food.

A major manufacturer of food oils and related food products suggested that fat intake should be reduced primarily by lowering saturated fatty acid intake. This comment raised questions about the possibility of increasing the risk of heart disease among consumers by reducing the relative proportions of polyunsaturated fatty acid intakes along with reductions in total fat intakes. It suggested that health claims for fat and cancer were justified only for foods especially low in saturated fat rather than total fat.

Finally, the Government of Canada submitted information that it considered helpful in the context of increased harmonization of regulations or standards affecting trade in specific products. The Director General, Food Directorate, Health and Welfare Canada, described the official position of Canada on the relationship of diet and nutrients to disease, including cancer, and the metabolic effects of nutrients, including fat, as stated in the volume "Nutrition Recommendations, the Report of the Scientific Review Committee—1990" (Ref. 9).

The conclusions of the Canadian Scientific Review Committee on fat and cancer were that "the present level of total fat, and particularly of saturated fat, in the Canadian diet constitutes a risk factor for cardiovascular disease and possibly for certain other diseases including some forms of cancer." The Committee recommended that total fat intakes of Canadians be no more than 30 percent of energy. The Director General also stated that food label health claims or messages regarding the role of fat in cancer risk could result in a food product being classified as a drug because the Food and Drug Act in Canada "prohibits the advertising and sale to the general public of a food that is represented either by label or in advertising as a treatment, preventative or cure for some 46 diseases, disorders or abnormal physical states including cancer."

II. Review of the Scientific Evidence

A. Federal Government Documents

In "The Surgeon General's Report on Nutrition and Health" (Ref. 4), the potential relationship of dietary fat to cancer risk was evaluated by reviewing results of a range of different types of studies. The report concluded that, although not yet conclusive, epidemiological and animal data support an association between dietary fat and the risk of cancer, especially breast, colon, and prostate cancer. The report stated that the effects of different types of dietary fat (i.e., saturated versus unsaturated) have not been separated in most human studies and considerable uncertainties remain to be resolved.

The Surgeon General's report concluded that the weight of the studies are strongly suggestive of the role for dietary fat in the etiology of some types of cancer (Ref. 4, p. 194).

The conclusions of the other authoritative documents from the Federal government listed above support the positive relationship between dietary fat and the risk of some types of cancer, particularly breast, colon, and prostate. These conclusions were the basis, in part, for the "Nutrition and Your Health: Dietary Guidelines for Americans" report that recommended calorie intake from total fat be less than 30 percent (Ref. 6).

B. Other Documents and Statements

The NRC's report "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 3) included the recommended goal to reduce total fat intake to 30 percent or less of calories. It stated that although less persuasive than the data supporting the fat and cardiovascular disease relationship, the weight of the evidence indicates that high fat diets are associated with a high risk of several types of cancer, especially of the colon, prostate, and breast. This report reviewed epidemiologic data as well as supportive evidence from animal studies that examined the mechanism of carcinogenesis.

The WHO study group report, "Diet, Nutrition, and the Prevention of Chronic Diseases" (Ref. 7) that presented the collective views of an international groups of experts, concluded that—

> * * * even though the "relationship between specific dietary components and cancer are much less well established than those between diet and cardiovascular disease, * * * a review of the evidence indicated that a high intake of total fat and in some case-control studies also saturated fat is associated with an increased risk of cancers of the colon, prostate, and breast. The epidemiological evidence is not totally consistent, but is generally supported by laboratory data from studies in animals. * * * [I]ntakes of less than 30 percent of total energy will be needed to attain a low risk of fat-related cancers. * * * [M]ost expert groups now consider it prudent to reduce fat intakes in Western societies from the prevailing figure of about 40 percent of energy towards 20 to 30 percent figure.

C. Review of the Scientific Literature

1. Evidence Considered

To the extent possible, the agency evaluated data from studies in humans as well as in animals. The criteria that the agency used to select pertinent recent studies required that they have been published and conducted after NAS' "Diet and Health" was published (i.e., after 1988), and that they:

(1) Present primary data carried out in animal or in human studies;

(2) Be available in English;

(3) Include direct measurement of dietary fat intake as a single nutrient or as a component of foods; and

(4) Include direct measurement of risk of cancer (prognostic indicator, incidence, development, prevalence, or mortality).

FDA considered that experiments in different animal species can take genetic variability into account and permit more intensive observation under controlled experimental conditions. However, the agency believes that extrapolation of data from animal studies to humans is limited by the differences in metabolism and physiology between animals and humans.

Various types of epidemiologic studies in humans also have limitations in methodology. The strengths and weaknesses of different kinds of epidemiologic studies and the methodologies for dietary assessment relevant to risk of chronic diseases are reviewed elsewhere (Ref. 3, pp. 23–32). Despite the limitations in epidemiologic studies, repeated and consistent findings of an association between certain dietary factors and diseases are likely to be real and indicative of a cause-and-effect relationship. Studies in animals can be used to confirm findings in humans and to elucidate mechanisms involved.

2. Evaluation Criteria

The data in humans and animals have been evaluated against general criteria for good experimental design, execution, and analysis. The criteria used in evaluating studies in animals include:

(1) Whether experimental diets were within physiological ranges of intake, particularly whether levels of fish oil or total fat in the diet were within the range of current human consumption and whether the diet provided adequate linoleic acid for growth of the host and tumor cells (There is evidence to support a linoleic acid requirement for optimal tumorigenesis. In a dose-response study, O'Connor et al. (Ref. 27) tested

azaserine-induced pancreatic tumorigenesis by measuring the development of atypical acinar cell nodules (AACN) in rats. AACN development was not affected when the diet contained less than 5 weight-percent corn oil but was increased as the omega-6:omeg-3 fatty acid ratio increased if the diet contained more than 5 weight-percent corn oil. This result is consistent with the reports by Ip et al. (Refs. 20 and 71) that there is a linear relationship of linoleic acid intake to mammary tumor development in rats up to an intake level of 4 to 5 weight-percent.);

(2) Whether confounding factors were controlled, particularly whether isocaloric diets were used;

(3) Whether the animal species selected for study were sufficiently similar to humans in responses to dietary modification;

(4) Whether the number of subjects was large enough to produce reliable data;

(5) Whether duration of exposure and period of observation were appropriate; and

(6) Whether the methods used in the measurement of disease endpoints were reliable and accurate.

The criteria used in evaluating human epidemiological studies included:

(1) Reliability and accuracy of the methods used in food intake analysis and measurement of disease endpoints;

(2) Choice of control subjects (e.g., hospital-based versus population based);

(3) Representativeness of subjects;

(4) Control of confounding factors, particularly energy intake which has a high correlation with fat intake, in data analysis;

(5) Potential for misclassification of individuals with regard to dietary exposure or disease endpoints;

(6) Presence of recall bias and interviewer bias; and

(7) Degree of compliance and how compliance was assessed.

FDA evaluated the weaknesses and strengths of individual studies (see Tables 1 and 2, assessment column). The strength of the overall combined evidence (e.g., epidemiologic studies and animal studies) was then assessed taking into account the strength of the association, the consistency of findings, specificity of the association, evidence for a biological mechanism and presence or absence of a dose-response relationship. FDA's conclusions reflect the strength, consistency, and weight of the data.

3. Review of the Evidence

a. *Animal studies.* Twenty-one animal studies were reviewed and critiqued in Table 1. Most studies used rats or mice, and a few studies used hamsters. Most rodent studies used a known cancer initiator, promoter, or both in conjunction with fats. A few studies used the transplant technique of existing tumor cells or cell lines.

i. *Level of fat in the diet.* Fourteen of the reviewed animal studies examined the effect of levels of dietary fats on incidence or development of cancer at the following sites: mammary gland (Refs. 10, 11, and 12), colon (Refs. 13 through 16), pancreas (Refs. 17 through 19), lung (Refs. 12, 21, and 22), gallbladder and common duct (Ref. 19), and skin (Ref. 23). The range of fat level tested, in most studies, was 5 to 20 percent by weight. The major dietary fat source was corn oil or beef tallow. Eleven of the studies examined the effect of omega-3 fatty acids in the development of cancer at the following sites: mammary gland (Refs. 12, 24, and 25), colon (Refs. 15, 16, and 26), pancreas (Ref. 27), lung (Ref. 12), skin (Refs. 28 and 29), as well as lymphoma and thymoma (Ref. 30), and sarcoma (Ref. 31). The major omega-3 fatty acid sources tested were menhaden oil and maxEPA. MaxEPA contains both eicosapentaenoic acid and docosahexaenoic acid as its major fatty acids, while menhaden oil contains only eicosapentaenoic acid as its major fatty acid.

Although there were few studies that examined the effect of fat consumption with lung and skin cancer, their results are consistent. All three studies of lung tumorigenesis showed an adverse effect of high fat versus low fat diets (Refs. 12, 21, and 22). Similar results were observed for the single study of skin tumorigenesis (Ref. 23).

However, mixed results were observed for tumorigenesis at the mammary gland, colon, and pancreas. One study showed a high risk of mammary cancer with high fat intakes (Ref. 11). Two studies showed no significant relationship of mammary tumorigenesis with fat intakes (Refs. 10 and 12). Shao et al. (Ref. 10) also reported no association between intake of total fats and mammary tumorigenesis in mice. However, the very high nontumor-related death rate (26 of 60 total) observed among the experimental animals makes it difficult to interpret the findings.

For colon cancer, one study (Ref. 16) showed a high risk of colon tumorigenesis with high fat intakes. A second study (Ref. 15) showed a significant relationship of a high fat diet to tumor incidence, but not tumor multiplicity. A third study (Ref. 14), however, showed no association. Sinkeldam (Ref. 13) also reported a significant effect of high fat on N-methyl-N' -nitro-N-nitrosoguanidine-induced colon tumorigenesis in rats. However, the results might have been confounded by an inadequate provision of linoleic acid in the diet.

Similarly, for pancreatic cancer, one study (Ref. 17) showed a positive relationship, but another showed inconsistent effects, of fat intake on different lesions: adenoma, adenocarcinoma, or carcinoma in situ (Ref. 19). Appel et al. (Ref. 18) did not find a significant difference in azaserine induced pancreatic neoplasms in rats between a group of rats given the 20 percent by weight lard (20 percent of the diet as measured by weight, not calories) and a group receiving a combination of 4.5 percent by weight lard and 0.5 percent by weight safflower oil. However, the low lard diet might not have provided adequate linoleic acid for growth of tumor cells.

Although the results of the animal studies are not in complete agreement, taken as a whole, and considered in the light of the aforementioned criteria, rodents consuming a high fat diet experienced significant elevation in the occurrence of tumors as measured by incidence, multiplicity, or metastasis. As discussed above, some animal studies showed significant reductions in the risk of tumorigenesis by reducing fat intakes from 20 percent by weight to 5 percent by weight. However, there was no dose-response study that quantitatively delineated the level of fat reduction in the diet necessary to cause reduced tumorigenesis. Tumor yield was enhanced when a high fat diet was fed after, but not before, initiation of tumorigenesis, which suggests a promotional effect of dietary fat (Refs. 16 and 23).

ii. *Fat level versus energy (calorie) intake.* Intake of dietary fat is highly correlated with energy (in this document, energy is used in place of calorie) intake, and the question has been raised as to whether energy intake or fat intake is the major dietary factor affecting tumorigenesis. In many recent animal studies, researchers have tried to determine the independent effect of dietary fats on tumorigenesis by using isocaloric diets or by training experimental animals to consume similar energy. Most of these studies with similar energy provisions among test groups showed significant associations between dietary fat level

and cancer risk: mammary tumors (Ref. 11), pancreatic tumors (Ref. 17), and skin tumors (Ref. 23). One study (Ref. 19), however, with similar energy provisions showed inconsistent results in N-nitrosobis (2-oxopropyl) amine-induced pancreatic ductular tumorigenesis. In this study, high fat significantly increased multiplicity of carcinomas in situ but not multiplicities of adenomas or adenocarcinomas. In addition, from a Murine mammary tumor virus-induced mammary tumor study in mice, Shao et al. (Ref. 10) reported that energy consumption rather than fat level affects tumorigenesis. However, this study had severe limitations in its methodology and execution because of a high, unexplained, nontumor death rate (26 of 60 total mice) which was even higher than the tumor death rate (19 of 60 total).

Abundant data have shown that energy restriction itself significantly reduces cancer risk probably through different mechanisms than the one through which dietary fat exerts its effect (Ref. 11). Although both fats and energy have been shown to have independent effects, precise relative contributions of fat and calories to cancer incidence is beyond the scope of this document.

iii. *Types of fat.* The effects of different types of fat (saturated fat, monounsaturated fat, and polyunsaturated fat) on tumorigenesis have not been studied extensively, and the results that do bear on this issue are as yet inconclusive. Generally, both a high corn oil diet (Refs. 11, 12, 17, 21 and 23) and a high lard diet (Ref. 13) exerted tumor-enhancing effects.

iv. *Fish oil, omega-3 rich.* The relationship of omega-3 fatty acids to cardiovascular disease is addressed specifically as a separate topic area. Therefore, this text will discuss only scientific data relevant to the association of omega-3 fatty acids with cancer.

Most studies, although concluding that a diet high in fish oil suppresses tumorigenesis, are limited by flaws in methodology. The main limitation is that the testing dose of fish oil in the diet, from 10 to 20 percent by weight in most studies, is unrealistically high for the current U.S. diet. Another limitation is that the diets under study often contained fish oil as the sole fat source or contained very high amounts of fish oil with very low amounts of corn oil.

Those very high fish oil diets would not have provided adequate linoleic acid for growth of the tumor cells. There may be a dietary requirement of linoleic acid at 3 to 5 percent by weight to yield a maximum carcinogenesis at the mammary gland and pancreas in rodents. The amount of linoleic acid required for maximal tumorigenesis is higher than the linoleic acid requirement for growth of the rodents, exclusive of the tumor cells (1 to 2 percent energy, which means 1 to 2 percent of the total dietary intake as measured in calories). The linoleic acid requirement for tumorigenesis has not been examined for tumors other than mammary and pancreatic. However, it is not possible to rule out the possibility that linoleic acid deficiency, rather than fish oil, might have caused, at least in part, the observed tumor suppression in fish oil studies. Therefore, FDA did not include fish oil studies in which the animals received very limited linoleic acid provision in their diets in the following discussion.

There are few fish oil studies in which the linoleic acid provision seems adequate for growth of tumor cells as well as for the animal in which the tumor is present (Refs. 12, 15, 16 and 27). Reddy et al. (Ref. 16) reported that azoxymethane-induced colon tumorigenesis in rats was significantly suppressed by a very high level of fish oil (18.5 percent by weight) diet compared to high levels of corn oil in the diet. Unlike the effect of total fat on tumorigenesis, the effect of fish oil was evident during the initiation as well as the postinitiation period.

O'Connor et al (Ref. 27) studied the relationship of a linearly increased omega-3:omega-6 fatty acid ratio in the diet with azaserine-induced pancreatic AACN. In this study, test levels of fish oil and total fat included the level of current consumption by the U.S. population. An increased omega-3:omega-6 ratio at 0.01 to 7.0 significantly decreased AACN in number and volume. There was significant regression between an increased omega-3:omega-6 ratio and decreased AACN diameter.

Deschner et al. (Ref. 15) reported a biphasic response of fish oil on azoxymethane-induced colon cancer in mice. In this study, a 4.4 percent fish oil to 16 percent corn oil diet significantly enhanced the tumorigenesis while a 10.2 percent fish oil to 10.2 percent corn oil diet suppressed it. Because the corn oil level is not held constant as the fish oil concentration is varied, it is not possible to comment on the tumorigenic effect of fish oil alone, though this does suggest that an increase in the fish oil to corn oil ratio may cause a decrease in tumor production. Adams et al. (Ref. 12) reported a nonsignificant tumor inhibiting effect of high (15.5 to 20.5 percent by weight) fish oil on transplanted mammary tumorigenesis in rats.

Although most studies consistently concluded that there is a suppressive effect of fish oil on tumorigenesis, the results cannot be extrapolated to humans because of study design limitations described above.

v. *Biochemical mechanisms.* Although several mechanisms have been proposed, the biochemical mechanism by which fats affect tumorigenesis has not been definitely established. While the required level of linoleic acid intake for optimal expression of mammary and pancreatic carcinogenesis in rats has been determined to be 4 to 5 percent by weight in the diet, how linoleic acid affects tumor development is not yet clear.

Several hypotheses about the mechanism of enhancement have been debated. One suggestion is that eicosanoid synthesis and changes in the fluidity or microenvironment of cell membranes affect tumorigenesis (Ref. 32). Another proposed mechanism is that polyunsaturated fatty acids may promote fat peroxidation at cell membranes or subcellular sites such as deoxyribonucleic acid (DNA), mitochondria, or microsomes, leading to the initiation of carcinogenesis (Ref. 32). A third suggestion is that dietary fats alter immune function, gene expression, and metabolism of chemical carcinogens (Refs. 34 and 35). Fats may also increase levels of estrogen and androgen, thereby enhancing the risk of such endocrine-responsive tumors as cancer of the breast and prostate (Ref. 36).

With regard to colon cancer, the effects of free fatty acids and bile acids on the colonic epithelium have also been debated. The ionized forms of these substances may be irritating and toxic to colonic epithelial cells and may increase cancer risk by promoting or possibly initiating colon carcinogenesis. Bile acids, particularly those modified by intestinal enzymes, may also increase cancer risk by accelerating turnover of intestinal mucosal cells (Ref. 33). Omega-3 fatty acids found in fish oil may suppress tumorigenesis by an altering eicosanoid production.

b. *Human studies.* FDA considered the following kinds of human studies in this review of the role of dietary fats in cancer: (1) Correlational (ecologic) studies—correlational studies examine the relationship between the exposure and health outcome among populations using grouped data. Because these studies do not examine relations among individuals, they have been regarded traditionally as useful for generating hypotheses rather than definitively

testing such hypotheses; (2) analytic epidemiologic studies—studies that involve comparisons of individuals have been regarded as the strongest type of observational evidence in human populations. In case-control studies, the relationship of an attribute to the disease is examined by comparing persons who already are diagnosed with cancer (cases) to persons without cancer (controls). A potentially serious limitation of the case-control study is that diet is assessed in the cases after diagnosis, so that cases may unintentionally overestimate or underestimate fat intake. Cohort studies compare individuals who have been exposed to a risk factor to those who have not and observe the individuals over time to determine if disease develops. In cohort studies, diet is assessed at the beginning of followup, before cancer develops.

Two criticisms have been raised in regard to results of the analytical epidemiologic studies of dietary fats and cancer. Such studies are often carried out in populations with a fairly narrow range of fat intake. Thus, it is difficult to show a dietary fat effect, especially if the true protective effect of a low-fat diet emerges only at a level below the intake of most members of the study population. Also, because there is considerable error in the assessment of diet, there may be considerable measurement error resulting in misclassification of a substantial proportion of subjects. Homogeneity of dietary intake in populations, together with misclassification of dietary data, tends to weaken the observed association and limits the ability of epidemiologic studies to demonstrate a true direct relationship between dietary fats and cancer.

Thirty-one original epidemiological research articles published since 1987 were reviewed and are critiqued in Table 2.

i. *Breast cancer.* In relation to breast cancer, 2 ecologic studies (Refs. 37 and 38), 2 cohort studies (Refs. 39 and 40), 11 case-control studies (Refs. 41 through 51, and Refs. 87 and 89), 2 surveys (Refs. 52 and 53), and 6 studies examining prognostic indicators of breast cancer (Refs. 53 through 58), and 1 metaanalysis of 12 case-control studies (Ref. 73) are included in Table 2.

The Hursting, et al. correlational (ecologic) study (an international correlation study combining data from 20 countries (Ref. 38)) found significant associations between estimated total fat intake and the incidence of breast cancer. Energy intake, which is highly correlated with fat intake, was adjusted in the data analysis. Therefore, the effect of dietary fat on the cancer incidence was assessed independently of the effect of energy intake. When the results were adjusted for intake of other component fats as well as total calories, the intake of saturated fatty acids was significantly associated with the incidence of breast cancer. The intake of omega-6 polyunsaturated fatty acid was also associated with breast cancer incidence. However, intake of monounsaturated fatty acids or omega-3 polyunsaturated fatty acids was not associated with any cancer risk.

In another correlational study, Prentice (Ref. 37) also examined the relationship between estimated per capita fat intake and breast cancer in 21 countries. Dietary fat, but not protein or carbohydrates, was significantly associated with breast cancer incidence.

In conclusion, the correlational studies demonstrated a significant positive association between dietary fat and breast cancer. The effect of dietary fat on breast cancer risk seems to be independent of the effect of energy. No specific fat type was found to be responsible for the observed risk of breast cancer.

Most of the case-control studies found a significant association between dietary fat intake and breast cancer risk (Refs. 44, 46, 47, 50, 51 and 87). Among those six studies with positive results, three studies (Refs. 46, 50 and 87) adjusted energy intake in the risk estimation. Gerber (Ref. 43) reported a borderline ($p=0.07$) association but did not adjust for energy intake. Holm (Ref. 53) reported that patients with higher fat-energy intakes had larger tumors than patients with less fat-energy and higher carbohydrate-energy intakes. However, the authors did not consider the possible confounding effect of lead time (the period of time between start of tumor growth and clinical diagnosis of cancer) among individuals with different levels of fat intake. A case-control study investigating the relationship between diet and histologic types of benign breast disease among Canadian women (Ref. 89) found that severe atypias and borderline carcinomas in situ were associated with frequent meat fat consumption but the results were not statistically significant.

Two studies (Refs. 42 and 45) resulted in no associations. In one (Ref. 42), intakes of energy, protein, or carbohydrates were also not associated with the risk of breast cancer. However, dietary habits of the population may have been homogeneous, thus reducing the ability to detect variation in disease risk associated with variation in dietary intakes. In the other negative study by Pryor (Ref. 45), subjects (ages 20 to 54) were asked about their food habits during the adolescent period. Errors in recall of dietary intake up to 40 years before might have biased the results, because of a selective memory difference between the cases and the controls.

In a study of 85 Israeli women, Eid and Berry (Ref. 52) reported that fatty acid composition in breast tissue was not associated with the risk of breast cancer. In this study, the percent composition, but not the amount of fatty acids, was reported. Studies in rodents have demonstrated that after a requirement for linoleic acid is met, total amount rather than type of fat in the diet is responsible for tumorigenesis. Therefore, the results of Eid and Berry are not contradictory to the current fat and cancer hypothesis. On the other hand, Neoptolemos et al. (Ref. 59) found that tissue arachidonic acid was decreased in colon cancer patients whereas there was no difference in dietary intake. The authors suggested a possible disturbance in fat metabolism in cancer patients.

Howe (Ref. 73) performed a meta-analysis of 12 case-control studies of diet and breast cancer. He found a consistent, statistically significant positive association between breast cancer risk and saturated fat intake in post menopausal women. However, he was unable to adjust the results for total caloric intake.

Considered together, the case-control studies support the conclusion that there is a positive association between dietary fat and breast cancer. The effect of fat intake on the risk of breast cancer is independent of the effect of energy intake. The total amount of fat rather than any specific type of fat seems to be responsible for the elevated risk of breast cancer.

The Howe et al. cohort study, (Ref. 40) found a weak but significant association between total fat intake and the risk of breast cancer in a prospective study in a large cohort (56,837 women, 519 cases during a 5-year followup). The group that consumed the highest amount of fat demonstrated a risk of developing breast cancer that was 1.3 times as great as the group that consumed the least amount of fat after adjustment for other sources of energy. Intake of various types of fat (saturated, monounsaturated, and polyunsaturated fatty acids) showed a general pattern of increasing risk of breast cancer with exceptions in the lowest quartile for intake of saturated and monounsaturated fatty acids. On the other hand, in a 20-year prospective study with a smaller cohort (3,988

women, 54 cases) in Finland, Kneckt et al. (Ref. 39) found no association between energy-adjusted fat intake and risk of breast cancer. The strength of the association between fat intake and the breast cancer risk could have been underestimated in this study because of possible changes over time in dietary habits during the 20 years before diagnosis.

The results of these two prospective studies are contradictory regarding the relationship between dietary fat and cancer. To date, only a small number of prospective studies that have examined this association have been completed. Because of the long latency period of breast cancer, a suitable length of time for a prospective study is likely to be 20 years or more, which presents many difficulties in its administration. In addition, in order to demonstrate an effect, the fat intake of the population would have to show sufficient variation to detect an effect.

To test the feasibility of low-fat dietary maintenance over time, a 2-year intervention study by Insull et al. (Ref. 60) required that subjects maintain a diet comprised of only 20 percent of total calories for 2 years. Compliance was good, thus supporting the authors' inference that studies that requiring maintenance of a low-fat diet are feasible.

ii. *Colon cancer.* There have been few studies published on the relationship of dietary lipids to colon cancer since the authoritative documents. An overview of these studies is given in Table 2 and discussed below.

The Hursting, et al. correlational (ecologic) study (Ref. 38) found a significant association of energy-adjusted, estimated total lipid intake and the incidence of colon cancer. When the results were adjusted for intake of the saturated fat component of lipids as well as total calories, the intake of saturated fat was significantly associated with the incidence of colon cancer. The intake of omega-6 or omega-3 polyunsaturated fatty acids were not associated with the risk of colon cancer. (See Table 2 for detailed critiques for each study.) Morales Suarez Varela-et al. (Ref. 90) evaluated the relationship between Spanish diet and rectal or colon cancer and found a positive correlation between rectal or colon cancer and total fat consumption. However, the results were not adjusted for total energy intake or for lifestyle confounders such as tobacco smoking.

A case-control study in Utah (Ref. 61) also reported a significant association of total fat intake with the risk of colon cancer in both females and males. In females, the group consuming the greatest quantity of total fat exhibited 1.9 times the risk of colon cancer as the group consuming the lowest quantity. In males, the risk was 2.0 times as great. However, various lipid types (saturated fat, monounsaturated fat, and polyunsaturated fat) were not consistently associated with the risk. Energy intake, not adjusted in the risk assessment, may have confounded the results.

De Verdieu (Ref. 77) in a Swedish case-control study of colorectal cancer found an increased risk with increased energy intake and with increased total fat intake but only the trend of increasing risk with increasing consumption levels was statistically significant. None of the individual fat consumption levels was associated with increased risk of colorectal cancer. The results were adjusted only for fiber intake and not for total energy. Also, there was a high nonresponse rate among the cancer cases, 21 percent, which may have biased the results.

Slattery, et al. (Ref. 88) conducted a case-control study of colon cancer in Utah that found a nonsignificant increase in cancer associated with total fat intake. The results were not adjusted for total energy intake.

Cohort studies—a prospective study of 88,751 registered nurses was performed by Willett. et al. (Ref. 62). During a 6 year followup period, 150 colon cancer cases were identified. After adjusting for the difference in age and energy intake, a positive association was found between fat and colon cancer. Specifically, the group with the highest total fat consumption demonstrated a risk of developing colon cancer that was 2.0 times as great as the group with the lowest fat intake. The groups with the highest consumption of animal fat, saturated fat, and monounsaturated fat also showed a higher risk of developing colon cancer of 1.9, 1.4, and 1.7 times the groups with the lowest consumption, respectively. Intakes of linoleic acid, vegetable oil, and cholesterol were not associated with cancer risk.

A prospective study of 8006 Hawaiian Japanese men (Ref. 85) was conducted to assess the impact of fat and calcium intake on the risk of developing colon or rectal cancer. The cohort was followed for 22 years. The results, which were not adjusted for total energy intake, demonstrated that fat intake did not affect colon or rectal cancer risk.

Thus, recent human studies on fat and colon cancer show an inconsistent association between intake of total fat and the risk of colon cancer. Many of the studies are difficult to interpret because the results were not adjusted for the effects of energy.

iii. *Other cancer.* Correlational (ecologic) studies (Ref. 38) demonstrated a significant association of energy-adjusted, estimated total lipid intake and prostate cancer but not with the incidence of cervical or lung cancer. When the results were adjusted for intake of component fats as well as total calories, the intake of saturated fat and omega-6 polyunsaturated fat was significantly associated with the incidence of prostate cancer. The intake of monounsaturated fat or omega-3-polyunsaturated fat was not associated with of risk of cancer. See Table 2 for detailed critiques for each study.

Ghadirian et al. case-control studies (Ref. 63) found significant associations of total lipid and saturated fat intake with the risk of pancreatic cancer in a case-control study in Montreal; however, cholesterol was not significantly associated with risk. Age, sex, energy intake, response status, and cigarette smoking habits were adjusted in the data analysis.

Baghurst, et al. (Ref. 75) in a case-control study of pancreatic cancer found an increased risk with increased cholesterol intake but not with polyunsaturated fatty acids. Thus, the results are somewhat contradictory. A well done case-control study of pancreatic cancer (Ref. 78) found no increased cancer risk associated with consumption of total fat, saturated fat, cholesterol, or omega-3 fatty acids. The results were adjusted for total caloric intake as well as for all major risk factors for pancreatic cancer other than diet. Finally, LaVecchia, et al. (Ref. 82) also found no relationship between pancreatic cancer and indicators of dietary fat in a well-controlled case-control study.

A case-control study in Hawaii (Ref. 64) showed that male lung cancer patients consumed significantly more fats (total fats, saturated fats, and monounsaturated fats) compared to the controls after adjustments for age, ethnicity, and cigarette smoking. However, there was no significant association between lipid intakes and risk of lung cancer in females. Another case-control study of lung cancer (Ref. 79) found a borderline increased risk of lung cancer associated with high levels of cholesterol consumption but not with total fat consumption. A case-control study of laryngeal cancer found no association with indicators of dietary fat (Ref. 81).

Steineck (Ref. 65) reported a dose-response relationship between total fat intake and the risk of urothelial cancer

in a case-control study in Sweden. Gender, age, and smoking habits, but not energy intake, were adjusted in the data analysis. Maclure, et al. (Ref. 83) found a weak association between risk of renal cancer and fat consumption. (See Table 2 for detailed critiques of these studies.)

Slattery, et al. (Ref. 86) in a case-control study of prostate cancer found no association with a high fat diet consumed as adolescents and a slight association with a high fat diet consumed by cases as adults.

Thus, one correlational study found a positive, energy-independent association of total fat intake with the risk of prostate cancer but not with the risk of cervical or lung cancer. One case-control study found a positive, energy-independent association of total fat intake with the risk of pancreatic cancer, but three other case-control studies of pancreatic cancer found no association with fat intake. The results of two case-control studies of lung cancer were not consistent for males and females, thus raising questions of interpretation. Various types of fat did not show any specific effects on risk of the various cancers examined. In conclusion, there is some evidence that total fat intake may increase the risk of prostate cancer but not the risk of pancreatic, cervical, pancreatic or lung cancer. The effect of fat seems to be independent of the effect of energy.

iv. *Studies testing fat-containing foods.* A few studies tested the association of lipids as constituents of food with the risk of breast cancer (Refs. 41, 44, 46, 48, 49, 62 and 65 through 68). The results of these studies were contradictory. Meat consumption was positively associated with risk of colon cancer or rectal cancer (Refs. 62, 66 and 67) and with stomach cancer (Ref. 76), but not with risk of breast cancer (Refs. 41, 44, 46 and 49), lymphoma (Ref. 68), urothelial cancer (Ref. 65), or oral cavity or pharyngeal cancer (Ref. 69). An additional case-control study of stomach cancer found a decreased cancer risk with increasing consumption of vegetable fat (Ref. 74). Consumption of whole milk (Ref. 48) or milk (Ref. 68) was significantly associated with the risk of cancer of the breast, colon, rectal, lung, bladder, prostate, oral cavity, and of lymphoma, but not with ovarian cancer (Ref. 84). Consumption of dairy products was significantly associated with the risk of cancer of the breast (Ref. 46), rectum (Ref. 67), and lymphoma (Ref. 68) but not with the risk of colon cancer (Ref. 67). Consumption of margarine was not associated with the risk of colon cancer (Ref. 66).

Methodological limitations inherent in case-control studies using food frequency questionnaires may have contributed to the difficulty of interpreting these results. These limitations include recall bias, interviewer bias, inconsistency in estimation of food consumption, and homogeneity of the population tested. Interactions among nutrients or other food components beyond fat might also have weakened the results.

4. Other Relevant Information

a. *Breast cancer and colon cancer: public health aspects.* Breast cancer is the second leading cause of cancer death among women. In 1990, approximately 44,000 women died of breast cancer in the U.S., while 150,000 new female cases were diagnosed. Approximately 1 woman in every 10 will develop breast cancer in her life (Ref. 1, pp. 415–6). The prevalence of breast cancer in the United States was estimated to be 1,517,882 cases in 1990. Thus breast cancer represented 24 percent of all cancers in 1990 and 39 percent of all cancers in females (Ref. 73).

Breast cancer risk increases with age, but the slope of the age-specific incidence is different before and after menopause. Risk rises rapidly up to about the age of 50 to 55, at which time the rate of increase slows or even reverses in some populations. After menopause, another rise occurs in high-risk populations.

Breast cancer has tended to be more common among higher socioeconomic groups and among Caucasians. Recently, however, rates have been rising among blacks, Hispanics, and people of Asian origin. The health care costs for breast cancer for 1990 are estimated at $8.5 billion, with an additional $16.5 billion, if lost wages due to disability and early mortality are considered (Ref. 73).

Colon cancer is a common disease in developed countries. It is the third leading cause of cancer death in the western world, exceeded only by lung and breast cancer. In the United States, colon cancer is a major cause of illness and death, accounting for 14 percent of all cancers diagnosed. The current U.S. age-adjusted incidence rate for colon cancer is 34.7 new cases per 100,000 population (Ref. 70). In 1990 the prevalence was 338,980 cases in men and 432,435 cases in women in the United States (Ref. 73). Both incidence and mortality from colon cancer have been relatively stable for the past 30 to 40 years. Recently, however, there has been an indication that mortality is decreasing among women in North America and possibly among men in the United States (Ref. 3, p. 118). Health care costs for colon cancer (1990) were estimated at $4.3 billion, with an additional $8.4 billion in lost wages due to disability and early mortality (Ref. 73).

b. *Potential safety concerns of dietary fat intake restriction.* Restriction in the intake of dietary fat may reduce the consumption of essential fatty acids. The requirement of linoleic acid to avoid essential fatty acid deficiency is 1 to 2 percent of total caloric intake. Currently, the average linoleic acid consumption in the U.S. ranges between 5 and 10 percent of total calorie intake, and deficiencies of essential fatty acids are rare in the U.S. Thus, a reduction of total fat consumption from the current 36 to 37 percent of total calorie intake to about 30 percent is not likely to cause essential fatty acid deficiencies in the general population.

5. Conclusions

Although the results of animal studies are not entirely consistent, taken as a whole, the results show that high fat diets enhance carcinogen-induced tumor development of the mammary gland, colon, pancreas, and lung, independent of the effect of energy intake. There seems to be an optimal intake of linoleic acid to yield maximum mammary and pancreatic carcinogenesis in rats. The amount of dietary linoleic acid (3 to 5 percent by weight) for maximum mammary tumorigenesis in rodents is higher than the linoleic acid requirement for the rodent, exclusive of the tumor cells (1 to 2 percent by energy), and approximates the current, average consumption of linoleic acid in the U. S. Once the linoleic acid requirement is met, the total amount of fat in the diet, rather than types of fat, seems to be responsible for tumor development (Refs. 20 and 71).

The effects of different types of fat on tumorigenesis have not been studied extensively, and the results are as yet inconclusive. Generally, both a high saturated fat diet and a high polyunsaturated fat diet show tumor-enhancing effects. Most studies that examined the effects of omega-3 fatty acid-rich fish oils on tumorigenesis consistently concluded there was a suppression of tumorigenesis. However, most of these studies were flawed in biological plausibility, and the results are not easily extrapolated to humans. The mechanism by which fat affects tumorigenesis has not been definitively established.

International correlational studies of human populations reported that dietary

lipid intake, independent of energy intake, is associated with tumorigenesis particularly of the breast, colon, and prostate but not with the incidence of cervical or lung cancer. These results suggest that the effect of fat intake on cancer incidence may be site-specific.

Four cohort studies were reviewed. In a 20-year followup study in Finland, energy-adjusted total fat intake was not associated with the risk of breast cancer. In a large, 5 year followup study in Canada, the energy-adjusted intake of total fat was weakly but significantly associated with the risk of breast cancer. All three fat types (saturated, monounsaturated, and polyunsaturated) showed a general pattern of increasing risk with increasing fat intake. In a large cohort study of 88,752 nurses, Willett et al. (Ref. 62) found a significant association of dietary total fat, animal fat, saturated fat, and monounsaturated fat with the incidence of colon cancer. However, a Japanese cohort study demonstrated that fat intake did not increase the risk of colon or rectal cancer (Ref. 85).

The total fat intake was associated with the risk of breast cancer in most, but not all, case-control studies: Six studies found a significant relationship, one study found a borderline association, and two studies found no relationship. As in the animal studies, no specific effects of different types of fat were found in these studies. In some studies, all types of fatty acids were associated with carcinogenesis; in some other studies, only saturated or monounsaturated fatty acids were associated.

Because energy intake and lipid intake are highly correlated, it is possible that the association between dietary fats and cancer is confounded by energy intake. It also has been demonstrated in animal and human studies that energy intake in excess of an essential requirement is of primary importance in determining the incidence of induced and spontaneous tumors. However, FDA s evaluation of recent research reports, both in animal and human studies, provides convincing evidence that the effect of dietary lipids on tumorigenesis is independent of the effect of energy.

Few studies evaluated fats in the context of overall food consumption. The results of studies of the association between the risk of cancer and consumption of meat, milk, or dairy products are inconsistent. Methodological limitations may have obscured any association that exists.

There have been no clinical trials or dietary intervention studies examining the quantitative relationship between reduction in fat intake and altered cancer risk in populations. Therefore it is not possible to conclude how much reduction in fat intake is necessary, or how soon in life it must commence, to reduce the risk of cancer in the U.S. population. Intervention studies of cancer are difficult to perform because the rarity of outcome for specific types of cancer requires enormous sample sizes. In addition, the long latency, 20 to 30 years for most types of cancer, makes such studies difficult and costly. For this reason, observational epidemiology studies are generally accepted as sufficient, as was the case for the first Surgeon General s Report on smoking. Nevertheless, the weight of evidence shows that a diet that is low in total fat is consistent with a low risk of some types of cancer.

The 17-year followup study of the National Center for Health Statistics' First National Health and Nutrition Examination Survey (Ref. 72) examined the relationships between dietary fat and the risk of cancer of the breast, prostate, and colon in 5,454 men and 7,876 women. No evidence of increased risk of cancer in the group with the highest fat intake was found. The difference in fat intake between the groups with the highest and the lowest fat intakes, 37 percent energy versus 32 percent energy, was not as great as the differences in fat intakes between countries. These results suggest that a reduction in fat intake to less than 30 percent of total calories may be needed to observe any reduction in cancer risk in the United States.

Thus, the conclusions of the authoritative reviews that dietary fats have an important influence on cancer incidence and mortality, particularly at sites such as the breast, colon, and prostate, are supported by the results of recent animal and ecological studies. Results of human prospective and case-control studies are less supportive, in part because of limitations in the experimental design. However, the majority of case-control studies are consistent with the conclusion that fat intake is associated with the risk of breast and colon cancer.

Although cancer at many sites was affected by fat intake in animal studies, epidemiologic studies failed to show convincing evidence for the fat and cancer relationship at various sites. Furthermore, an international ecologic study found an association between fat intake and cancer of the breast, colon, and prostate but not of the cervix or lung. These results suggest that the effect of fat on cancer may be site-specific.

From the review of other authoritative documents and recent research reports, the agency concludes that dietary fat intake may affect the risk of breast, colon, and prostate cancer. More studies are needed to examine the relationship between fat intakes and cancer at other sites.

No scientific evidence is available that demonstrates that any specific fat type is more causative of cancer than another. All types of fat (saturated, monounsaturated, and polyunsaturated) may be associated. Therefore, total fat content, rather than any specific type, may be responsible for the tumor enhancing activity of fat in the current diet of the U.S. population.

III. Tentative Decision to Authorize a Health Claim Relating Ingestion of Dietary Fat to Reduced Risk of Cancer

FDA has reviewed the Federal government and other review documents as well as recent research and review articles relevant to dietary fat and cancer risk. In addition, the agency considered all comments received in response to the **Federal Register** notice of March 28, 1991, requesting scientific data and information on fat and cancer. The agency has tentatively concluded that all the publicly available evidence supports an association between dietary fat and cancer risk. FDA tentatively finds, based on this evidence and the authoritative reports, that there is significant scientific agreement among qualified experts. The agency is proposing to authorize a health claim for fat and cancer on the label and labeling of foods provided that such statements comply with the requirements of proposed § 101.73. Under this proposal, the claim will convey the message that diets low in fat may reduce the risk of some types of cancer, particularly breast, colon, and prostate. FDA also tentatively concludes that the message must be restricted to these three types of cancer because of the limitations of scientific data about other types of cancer.

IV. Description of and Rationale for Regulations

A. Relationship Between Dietary Fats and Cancer

Based on all of the evidence, FDA has tentatively determined that there is significant scientific agreement among experts qualified by training and experience to evaluate such claims, that all of publicly available evidence supports the conclusion that diets high in fat increase the risk of cancer, and,

more importantly, that diets low in fat is associated with the reduced risk of cancer. FDA recites this fact in proposed § 101.73(b)(1) and states that the research to date shows that it is total fat, and not any particular type of fat that is associated with cancer risk.

The specific health claim topic, as described in section (3)(b)(1)(A)(vi) of the 1990 amendments was dietary lipids and cancer. FDA has tentatively found that the intake of dietary lipids is associated with cancers of the breast, colon, and prostate. This tentative finding is based on the conclusions of a number of comprehensive reports by the Federal Government and the NRC which identified cancers at these particular sites as having a relationship to dietary fats. It is also supported by research published since the authoritative reports to determine if more recent research would necessitate modification of previous conclusions.

B. Significance of the Relationship

To reflect, in part, proposed § 101.14(d)(2)(v), FDA is including in proposed § 101.73(b)(2) dietary guidelines to recommend that total fat intake be at or below 30 percent of calories. Currently, adults in the United States consume, on average, a total fat intake of 37 percent of calories. The proposed regulation states that significant public health benefits can be derived from decreased consumption of foods high in fat, including the reduced risk of breast, colon, and prostate cancer.

C. General Requirements

1. Conformity With Proposed § 101.14

Proposed § 101.14 sets forth the general provisions applicable to health claims. In proposed § 101.73(b)(3)(i), FDA is proposing that health claims relating to an association between dietary lipids and cancer must meet all requirements for health claims proposed in § 101.14, as set forth elsewhere in this issue of the **Federal Register**.

2. Qualifying Nutrients: Total Fat

In proposed § 101.73(b)(3)(ii), FDA is proposing that a health claim relating diets low in fats to reduce the risk of cancer must meet requirements for "low fat" or "fat free."

The evidence for the association between intake of dietary lipids and risk of cancer pertains to total dietary fats. In the companion document on general requirements for health claims for food (published elsewhere in this issue of the **Federal Register**), FDA is proposing that for a substance such as dietary fats for which a low level of intake is needed to achieve dietary goals, the substance be present in a food at a low enough level to justify a claim. FDA is proposing that that level be the level that is necessary to make a "low fat" or "no fat" claim. As proposed in the companion document on "Definitions of Nutrient Content Claims for the Fat, Fatty Acid, and Cholesterol Content of Foods," these levels are, for a "low fat" claim, less than 3 g of fat per reference amount customarily consumed, per labeling serving size, and per 100 g. For a "no fat" claim, FDA is proposing that the food contain less than 0.5 g of fat per reference amount customarily consumed and per label serving size.

As explained in the companion document on general requirements for health claims, FDA is proposing that the food contain "low" or "no" fat to ensure that it contains a level of fat that is appropriate for inclusion in a diet that is low in fat. FDA seeks comments on whether a food that qualifies for a "reduced fat" or comparative claim should also qualify to bear this health claim.

D. Specific Requirements

In proposed § 101.73(b)(4)(i), FDA is proposing to require that any health claim made relating to dietary lipids and cancer specifically state that it is diets that are low in fats that may reduce the risk of some types of cancer.

In proposed § 101.73(b)(4)(ii), to reflect the strength of the scientific evidence regarding the relationship of dietary lipids to risk of cancer, FDA is proposing that any health claim make clear that ingestion of diets low in fats "may" reduce the risk of cancer. This requirement is based on this relationship and is supported by evidence documented and summarized in Federal government reports, in other authoritative documents, and in the science review incorporated previously in this document. However, given the fact that the etiology of cancer is multifactorial the claim cannot state that a low fat diet will definitely reduce the risk of this disease.

In respect to the multifactorial nature of the disease in proposed § 101.73(b)(4)(iii), the agency is proposing to require that health claims acknowledge the existence of other risk factors for cancer in addition to the dietary risk factor of fat intake. The agency believes that this additional information provides a context that is essential for an understanding of the nutrient to disease relationship.

As for terminology, in proposed § 101.73(b)(4)(iv), FDA is proposing that health claims refer to the nutrient disease relationship using the term "total fat." This terminology is consistent with colloquial usage. Thus, the claim will be clear and not misleading to the public. It also reflects the available evidence. In proposed § 101.73(b)(4)(iv), FDA provides that a combined fat and cancer and fat and cardiovascular claim may be used if a food qualifies for both claims. In proposed § 101.73(a), FDA is summarizing the scientific evidence that establishes a relationship that exists between saturated fat, cholesterol, and total fat and cardiovascular disease. FDA is proposing to authorize health claims on qualifying foods that meet the criteria for "low" saturated fat, cholesterol, and total fat or no cholesterol and total fat.

For the estimation of attributable risk, in proposed § 101.73(b)(4)(v), FDA proposes that no statement may be made on the precise level of reduction of risk of cancer that may be expected as a result of consuming a diet low in total fat. This requirement is proposed in conformity with proposed § 101.14(d)(2)(iii) which requires that the claim not be misleading. The review of Federal government documents and other authoritative reports and more recent scientific evidence revealed no scientific agreement on a precise level of risk reduction for the relationship of dietary fat to cancers.

In § 101.73(b)(4)(vi), FDA is proposing that the claim may not specify the particular types of fats and fatty acids that may be related to the risk of cancer. FDA tentatively finds that the evidence is not sufficient to characterize the relationship more specifically than between cancer and total fat.

E. Optional Information

For total dietary context, in proposed § 101.73(b)(5)(i), FDA proposes to permit claims to refer to the latest U.S. Dietary Guidelines for Americans (Ref. 6). The agency is proposing to permit such references to help ensure that the claim is presented in a way that will help consumers to understand it in the context of a total daily diet. The agency recognizes that a statement about the importance of good nutrition that does not make a connection between any substance and a particular disease, as is the case with many of the Dietary Guidelines, is not a health claim. H. Rept. 101–538, 101st Cong., 2d sess. 20 (1990). However, as is stated in the document on the general principles for health claims, FDA believes that it is appropriate for it to provide for the use of governmental dietary information in conjunction with a health claim to

ensure that that information is used in a consistent and nonmisleading manner.

Providing additional health claim information, in proposed § 101.73(b)(5)(ii), the agency is proposing to allow manufacturers to provide more detailed information to consumers. This information may provide a more accurate and complete description of the relationships among both dietary fats and risk of cancer and heart disease. A statement on how to obtain this additional information may be provided in or near the health claim. Such additional information, however, is not a substitute for that required in a health claim.

F Sample Health Claims

FDA is also providing in proposed § 101.73(b)(6) two sample health claims. These model claims have been prepared by the agency to reflect all the requirements of proposed § 101.73. They are only samples, however, if these sample health claims are adopted by the agency, manufacturers will be free to use them. They will also be free to devise their own message provided that it complies with the regulation.

V. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VI. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VII. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VIII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

IX. Appendix to the Preamble—Consumer Summary on Dietary Lipids and Cancer and Dietary Lipids and Coronary Heart Disease

As described in the companion document (published elsewhere in this issue of the **Federal Register**) on general requirements for health claims, the agency is requesting comment on the need for consumer health claims summaries. The focus of the consumer summary would be to provide factual information to aid the consumer in understanding the diet-disease relationship. The following appendix is a proposed consumer summary on dietary lipids and cancer. The role or relationship of dietary fats to cancer risk is discussed, along with the relationship of dietary fats to coronary heart disease. FDA solicits comment on this document as explained in the proposal on general health claims published elsewhere in this issue of the **Federal Register**.

Appendix—Dietary Lipids and Cancer and Dietary Lipids and Coronary Heart Disease

Under the provisions of the Nutrition Labeling and Education Act of 1990, manufacturers may put clear information on the food label about the relationship between a nutrient, such as fat or cholesterol, and a disease or health-related condition. To prevent consumers from being misled, the Food and Drug Administration (FDA) allows only truthful label statements about diet and health relationships that are firmly supported by the current scientific evidence. There is agreement that the scientific evidence is strong enough to allow health claims about the association between total fat in the diet and the risk of some types of cancer and the association between saturated fat and cholesterol in the diet and the risk of coronary heart disease.

Many consumers have said that health claims on food labels could be useful to them in making improvements in their diets. However, label space is often limited. Therefore, this pamphlet provides information about diet and health claims that supplements what you may see on food labels.

In addition to the association between fat and cancer and between saturated fat and cholesterol and heart disease, FDA is allowing health claims about calcium and osteoporosis and sodium and hypertension. For information about these other diet and health relationships, write to: [TO BE INSERTED]

What is Coronary Heart Disease?

Coronary heart disease is a broad term that includes a number of diseases for which various medical names are used, including heart disease and atherosclerosis. Narrowing of blood vessels (medically called atherosclerosis) occurs in these diseases, which results in decreased flow of blood to some part of the body. The diseases include coronary heart disease that affects the heart and its supporting blood vessels, and other diseases that affect the blood vessels in other areas of the body Atherosclerosis can result in angina pectoris, heart attack, sudden death, stroke or other serious problems.

Atherosclerosis occurs because of raised fatty or fibrous deposits (plaque) that develop in the walls of blood vessels in the affected area. The process of plaque development is gradual, and often begins in childhood.

What is Cancer?

Cancer is not one disease, but more than 100 different diseases. In each of these diseases, cells begin to grow out of control at one site in the body, and these abnormal cells spread to other parts of the body.

Why Are Heart Disease and Cancer Major Public Health Concerns?

Coronary heart disease and cancer are public health concerns because they are the two leading causes of death in this country. Illness and death from these diseases cost billions of dollars in health care costs and in lost work. Moreover, early deaths from these two diseases cheat many victims of valuable years of life.

Despite the recent sharp decline in the death rate from this condition, coronary heart disease still accounts for the largest number of deaths in the United States. Cancer is the second leading cause of death in this country. The leading causes of cancer death are lung cancer, colorectal cancer, breast cancer, and prostate cancer.

What Causes Cancer and Coronary Heart Disease?

Both of these diseases are caused by a combination and interaction of multiple environmental, behavioral, social, and hereditary factors. It is clear that diet, one of the environmental factors, plays

an important role in the development of these diseases.

Heredity and other factors, including elevated blood serum cholesterol, cigarette smoking, high blood pressure, obesity, and an inactive life style, are known to increase a person's risk of developing coronary heart disease. Elevated blood cholesterol, one of the major risk factors for coronary heart disease, is associated with excess fat, especially saturated fat, and cholesterol in the diet.

Many studies have established a strong association between a diet high in saturated fat and cholesterol and increased risk of coronary heart disease. High saturated fat and cholesterol diets are estimated to be associated with one-third of the cases of coronary heart disease reported in this country.

The way diet affects blood cholesterol varies among individuals. However, blood cholesterol does increase in most people when they eat foods high in saturated fat and cholesterol and excessive in calories. Of these, saturated fat has the greatest effect; dietary cholesterol has less.

Cancer has many causes and several stages in its development. The risk factors for developing cancer include a family history of a specific type of cancer (such as breast, prostate or colon cancer), cigarette smoking, alcohol consumption, radiation, and dietary factors.

Currently, the strongest scientific evidence relating diet to cancer is that the amount of total fat in the diet may have a relationship with cancer. In particular, many experts agree that a high fat diet may influence the risk for developing breast, colon, and prostate cancers.

Not enough is known currently for scientists to decide whether different kinds of fats (animal or vegetable; saturated or unsaturated) may be responsible for an increased risk of developing cancer.

Because of scientific agreement that reducing total fat and saturated fat is likely to lower the rates of these two major chronic diseases, it is recommended that Americans 2 years of age and older choose a diet low in total fat and saturated fat. Animal products are the source of all dietary cholesterol. Eating less fat from animal sources will help to lower the cholesterol as well as the saturated fat in your diet.

Do Most People Get Too Much Fat, Saturated Fat and Cholesterol in What They Eat?

The average U.S. diet, it's estimated, contains about 37 percent of calories from total fat, 13 percent of calories from saturated fat, and 360 milligrams (mg) of cholesterol per day. Health experts recommend diets that contain 30 percent or less of calories from total fat, 10 percent or less of calories from saturated fat, and 300 mg or less of cholesterol a day. The U.S. Public Health Service has set a national health goal that all persons who are 2 years of age and older consume these levels of fat and cholesterol by the end of this decade.

How Do You Learn How Much Fat and Cholesterol Foods Contain?

You may or may not be able to tell that there's fat in a food by looking at it. Butter, margarines, shortenings, and oils are the more obvious sources of fat. In other foods, such as cheese, baked goods, nuts, and salad dressings, the fat is not as easily detected. Cholesterol content is not obvious at all in foods.

A good way to learn about fat and cholesterol content is to read nutrition labels. Most foods now have nutrition information on their labels.

The amounts of total fat and saturated fat in a serving of food are listed in grams (g) on the nutrition label. Cholesterol is listed in mg.

"Daily values" for fat, saturated fat, and cholesterol also appear on food labels. These numbers have been established by FDA for several nutrients that are important in diet and health relationships. The daily values are to help you learn how the amount of a nutrient in a serving of food relates to a reasonable amount for the day.

The daily value for total fat is 75 g, and for saturated fat is 25 g. That means total fat for a day of 75 g, of which no more than 25 g should be from saturated fat. These numbers are based on a 2,350-calorie diet that has 30 percent of calories from fat and 10 percent from saturated fat. A 2,350-calorie diet is about the calories recommended for an adult woman.

If you consume a different number of calories a day, it's not hard to figure out your own daily values for total fat and saturated fat. First, multiply the number of calories you consume by 30 percent (for example, $2000 \times .30 = 600$). Then divide that number by nine, which is the number of calories each g of fat provides (600 divided by 9 = 67 g of fat a day). Repeat for saturated fat ($2000 \times .10 = 200$; 200 divided by 9 = 22 g of saturated fat a day).

The daily value for cholesterol is 300 mg, which is an upper limit that is generally recommended for healthy people. A food that contains 150 mg of cholesterol per serving, therefore, would provide about half of the daily value for cholesterol.

What Do Label Claims About Fat and Cholesterol Mean?

In addition to the amount of fat and cholesterol listed on the nutrition label, you may see other claims about fat and cholesterol content on some food packages. There are two types of these claims—nutrient content claims and health claims.

Nutrient content claims describe the amount of fat, saturated fat, or cholesterol a food contains. These types of claims can be used on a label only if a food meets several definitions established by FDA.

Cholesterol Claims

A "cholesterol free" food has less than 2 mg of cholesterol and 2 g or less of saturated fat in a serving.

A "low cholesterol" food has 20 mg or less of cholesterol in a serving and in 100 g of food and 2 g or less of saturated fat in a serving.

A "reduced cholesterol" food has its cholesterol content reduced by 50 percent or more compared to the regular food product and contains 2 g or less of saturated fat in a serving.

Cholesterol claims may be made only on foods that contain a limited amount of fat (no more than 11.5 g per serving and per 100 g) unless the claim also tells the total amount of fat, for example, "cholesterol free, contains 12 g of fat per serving."

Fat Claims

A "fat free" food has less than a ½ g of fat in a serving and no added fat or oil.

A "low fat" food has 3 g or less of fat in a serving.

A "reduced fat" food has a 50 percent or more reduction in fat with at least a 3 g reduction in fat content.

A "low saturated fat" food has 1 g or less of saturated fat in a serving and no more than 15 percent of its calories from saturated fat.

A "reduced saturated fat" food has its saturated fat content reduced by 50 percent or more compared to the regular food product with at least a 1 g reduction in fat.

Also, the labels of some foods in which fat or cholesterol has been significantly reduced, but not enough to meet the definitions above, may have a statement that tells how much less fat or cholesterol the product contains than a comparable product; for example, "This pound cake contains 40 percent less fat than our regular pound cake."

Foods such as fruits and vegetables that meet the definitions for fat or cholesterol without special processing may have claims on them. However, the

label must say that fat or cholesterol is not usually present in the food, for example, "broccoli, a fat-free food," "frozen perch, a low fat food," or "raspberries, a low saturated fat food."

Health claims are those made about the relationship between the amount of a nutrient you eat and the risk of a disease, for example, between total fat and cancer or between saturated fat and cholesterol and heart disease.

Health claims about the relationship between fat and cholesterol and heart disease can only be made on products that are low in saturated fat and cholesterol, and have 15 percent or less of their calories from fat. To make a health claim, the product also cannot contain another nutrient that increases the risk of a diet-related disease other than atherosclerosis, for example, a high amount of sodium which has a relationship to high blood pressure.

Health claims about the relationship between fat and cancer can be made only on foods that are low in fat and do not contain another nutrient that increases the risk of a diet-related disease other than cancer.

These are some of the kinds of foods on which you may see health claims about nutrients related to cancer and heart disease: fruits, fruit juices, vegetables, breakfast cereals, dried peas and beans, skim milk, pasta products, and diet salad dressings.

Other Risk Factors for Cancer and Heart Disease

Coronary heart diseases and cancer are complex diseases with multiple causes, and they (usually) develop over a long period of life. Hereditary as well as environmental factors contribute to the risk for developing these diseases. In addition to practicing good nutrition, several other controllable factors are part of a healthy lifestyle and may help to decrease your chances of cardiovascular disease and cancer. These include maintaining a healthy body weight and good physical fitness, not smoking cigarettes, drinking only in moderation if at all, and not abusing drugs.

Facts To Keep in Mind

It's the total combination of foods that you eat regularly—both the kinds and the amounts—that is important in terms of good nutrition. Eating a particular food or a specific food is not a magic key that will assure you have a more healthful diet.

Eating a healthy diet, in itself, does not guarantee good health. A healthy diet, however, is an important part of a healthy lifestyle.

In addition to what you eat, many factors may be related to your own chance of developing a particular disease, for example, your heredity, your environment, and the health care that you get. Our knowledge about most diet-health relationships is incomplete, and will improve as scientific knowledge increases. However, enough is known today about some of these relationships to encourage specific dietary practices that are believed to be beneficial.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR Part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6, of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.73 is amended by adding paragraph (b) to read as follows:

§ 101.73 Health claims: lipids and cardiovascular disease and lipids and cancer.

* * * * *

(b) *Cancer*—(1) *Relationship between lipids (fat) and cancer.* (i) Cancer is not one disease, but a constellation of more than 100 different diseases, each characterized by the uncontrolled growth and spread of abnormal cells. Cancer has many causes and stages in its development. Both environmental and genetic risk factors may be involved in affecting the risk of cancer occurrence. Risk factors include a family history of a specific type of cancer, cigarette smoking, alcohol consumption, ultraviolet or ionizing radiation, and dietary factors.

(ii) The strongest positive association between fat intake and cancer risk has been found between total fat intake and some types of cancer. Based on the totality of the evidence available at this time, and despite some inconsistencies found in results of human studies, there is significant scientific agreement among experts, qualified by training and experience to evaluate such evidence, that diets high in total fat are associated with an increased cancer incidence. Research to date, although not conclusive, demonstrates that the total amount of fats, rather than any specific type of fat, is positively associated with cancer risk. The mechanism by which total fat affects cancer has not yet been established.

(iii) A question that has been the subject of considerable research is whether the effect of fat on cancer is site-specific. Studies which compared fat intake and cancer mortality in different countries or population groups found an association between total fat intake and cancer of the breast, colon, and prostate, but not at other sites. Although both human and animal studies are consistent in the association of fat intake with specific sites, the studies relying on animal data are more compelling. FDA concludes that the claim must be restricted to cancer of the colon, breast, and prostate due to the lack of adequate evidence for other types of cancer.

(iv) The question of whether the association of total fat intake to cancer risk is independently associated with fat intakes, or whether the association of fat with cancer risk is the result of the higher energy (caloric) intake normally associated with high fat intake, has been raised. After reviewing the evidence, FDA has concluded that there is adequate evidence from both animal and human studies to find that total fat intake alone, independent of energy intake, is associated with cancer risk.

(2) *Significance of fat intakes and risk of cancer.* Currently the average U.S. diet is estimated to contain 36 percent to 37 percent of calories from total fat. Current dietary guidelines and nutrition goals for the nation recommend that dietary fat intake be reduced to a level of 30 percent or less of energy (calories) from total fat. The scientific evidence supports the conclusion that this

lowered level is associated with a potential reduction in the risk of breast, colon and prostate cancer. Although there is evidence that reductions in total fat intake below the level of 30 percent of calories from total fat may confer even greater health benefits, the recommended levels for total fat were set at 30 percent of calories because they can be achieved without drastic changes in usual dietary patterns and without undue risk of nutrient deficiency.

(3) *General requirements.* A food label or labeling may contain a health claim stating that diets low in total fat may reduce the risk of some types of cancer, particularly colon, breast, and prostate cancer, in the general population provided that the following conditions are met by the product:

(i) The food meets all general requirements of § 101.14 for health claims.

(ii) The food meets requirements of § 101.62 for a "low fat" or "fat free" food.

(4) Health claims may be used on the label and labeling provided such statements comply with the following specific requirements:

(i) The claim states that diets low in fat (i.e., total fat) may reduce the risk of some types of cancer;

(ii) The claim is stated using words such as "may" or "might" in accordance with the strength of the evidence for the relationship;

(iii) The claim states that cancer has many causes, and that high total fat diets are only one of several factors associated with the risk of cancer;

(iv) In specifying the nutrient, the claim shall use the term "total fat", unless the food also meets the qualifications for a label statement on the cardiovascular disease-fat relationship in which case a combined statement may be used;

(v) The claim shall not quantitate the degree to which the risk of cancer may be reduced by diets low in total fat content; and

(vi) The claim shall not specify types of fats or fatty acids that may be related to the risk of cancer.

(5) Health claims describing the relationship between dietary lipids and cancer may include the following as optional information:

(i) The claim may indicate that low fat intake as part of a total dietary pattern is consistent with the latest U.S. Dietary Guidelines for Americans published jointly by the U.S. Department of Agriculture and the Department of Health and Human Services. Concepts or quotes from this publication may be used on the label provided that they are truthful and not misleading; and

(ii) The claim may include a reference that would direct interested consumers to more complete consumer information on the relationship of low total fat diets and cancer risk.

(6) The following sample health claims may be used on the label or labeling of a food to convey the relationship between dietary lipids (i.e., total fat or fat) and cancer:

Sample Health Claims

Developing cancer is associated with many factors, such as a family history of the disease, cigarette smoking, and what you eat. Eating a healthful, low fat diet may help reduce the risk for some cancers, including breast, colon, and prostate cancer.

Cancer is associated with many dietary and other risk factors. A diet low in total fat may reduce the risk of some types of cancers, including breast, colon, and prostate cancer.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

BILLING CODE 4160-01-M

Table 1

Dietary Lipids and Cancer: Animal Studies 1989-April 1991

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Shao et al., 1990 (Ref. 10)	The effects of energy source and energy restriction on tumor development and survival rate	Female, 4 to 5 month-old, C3H/Bi mice, 15 per group	40 weeks	Ad lib and 40% energy restriction High fat: 68.2% energy lard, free carbohydrate Low fat: 4.5% energy lard, 63% energy carbohydrate	Murine mammary tumor virus (MuMTV)	Mammary: No significant difference in incidence or survival rates between high fat and low fat groups Significantly increased incidence and survival rates with energy restriction Combined mortality from all causes (tumor-related and nontumor-related) were higher in the order of: low fat, ad lib > high fat, ad lib > high fat, restriction > low fat restriction (statistics not tested)	Energy consumption, not fat intake, may play a greater role in MuMTV-induced mammary tumorigenesis; however, the nontumor-death rate was very high (26 of 60 total) which greatly reduces the significance of the findings
Welsch et al., 1990 (Ref. 11)	The effect of caloric consumption and fat level on mammary cancer	Female, 55-day old, Spargue-Dawley rats, 41 to 42 per group	16 weeks	Ad lib. and 12% energy restriction High corn oil: 20 weight % Low corn oil: 5 weight %	7,12-Dimethylbenz(a) anthracene (DMBA)	Mammary: High fat diet significantly (~2 times) increased the yield (number and weight) of mammary carcinoma A 12% energy restriction significantly reduced the yield (number) of mammary carcinogenesis in high corn oil group, but not in low corn oil group The 12% energy restriction abolished the effect of fat level	When energy intake was sufficient, high fat corn oil significantly enhanced DMBA-induced mammary tumorigenesis in rats Because caloric intakes among groups were the same, the fat effect was independent of the energy effect Fat and energy might have separate functions in mammary tumorigenesis

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Sinkeldam et al., 1990 (Ref. 13)	Interaction of dietary fat (lard) and fiber on colon cancer	Male, 4-week-old, wistar rats, 30 per group	37 weeks	Ad lib 15 energy % lard 0.7 g fiber 2.2 per 3.8 100 Kilocalories (kcal) 27.5 energy % lard 0.7 g fiber 2.2 per 3.8 100 kcal 40 energy % lard 0.7 g fiber 2.2 per 3.8 100 kcal	N-methyl N-Nitro-N-nitrosoguanidine (MNNG)	Colon: High fat diet significantly enhanced incidence and multiplicity (see below, data pooled) % incidence fat energy% polyps carcinoma total tumor 15 44 9 48* 27.5 51 23* 60 40 61 11 62 fat energy % Multiplicity (#/tumor-bearing rats) Polyps Carcinoma Total Tumor 15 1.6 1.1 1.7 27.5 1.5 1.1 1.7 40 2.4* 1.5 2.6 High fiber significantly decreased body weights and abolished the effects of fat level on colon tumorigenesis *Means significantly different from other fat energy % within tumor type	High fat enhanced MNNG-induced colon tumorigenesis in rats; however, the response was neither dose-dependent nor consistently significant The results might have been confounded by inadequate provision of linoleic acid in 15% and 27.5% lard diet groups Energy intakes were similar among different fat groups; therefore, the fat effect was independent of energy effect

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Newberne et al., 1990 (Ref. 14)	Interaction of fat and vitamin A in colon tumorigenesis	Male, weanling, Spargue-Dawley rats, 25 to 30 per group	24 weeks	5 or 24 weight % corn oil Vitamin A 3 mg per kg 10 mg per kg 30 mg per kg	Dimethylhydrazine dihydrochloride (DMH)	Colon: High fat versus low fat: no significant difference in the incidence or malignancy Vitamin A significantly lowered the incidence in low fat group, but not in high fat group	Diets were not isocaloric; food consumption, body weights were not reported The differences in energy intakes and body weight changes might have confounded the effects of fat The high peroxidation level of high corn oil diet, which was not controlled to approximate human dietary conditions, might also have confounded the results
Birt et al., 1989 (Ref. 17)	To determine the energy effect in pancreatic tumorigenesis	Male, 6-week-old, Syrian hamster, 30 per group	91 weeks	Corn oil: 4.3 weight % 20.5 weight %	Tumor initiator: N-nitrosobis-(2-oxopropyl) amine (BOP)	Pancreatic ductular carcinoma: Both incidence (%) and yield (# carcinoma per effective animal) were significantly (3 to 4 times) enhanced in the high fat group compared to the low fat group; no differences in survival rates	Ad lib or pair feeding Caloric intakes were similar between groups; therefore the fat effect was independent of energy effect

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Appel et al., 1990 (Ref. 18)	Whether the linoleic acid level or the total fat level is the main determinant of pancreatic carcinogenesis	Male, weanling, SPF albino Wistar rats, 40 (lard group) or 23 (chow group) per group	15 month	High fat: 20 weight % lard 1.2 weight % linoleic acid Low fat: 4.5 weight % lard 0.5 weight % safflower oil 0.6 weight % linoleic acid Low fat supplemented: 1.4 weight % lard 3.6 weight % corn oil 2 weight % linoleic acid Chow: 6 weight % fat (3% linoleic acid)	Tumor inducer: azaserine	Pancreatic neoplasm: Linoleic acid supplementation did not significantly affect pancreatic neoplasm Fat level also did not significantly affect pancreatic neoplasm	The amount of dietary fat did not significantly affect azaserine-induced pancreatic carcinogenesis in rats; however, levels of linoleic acid in the test diets might not be adequate for optimal tumorigenesis The level of linoleic acid supplementation was too narrow to test the effect of linoleic acid Energy intakes were similar among groups

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Birt et al., 1990 (Ref. 19)	The effect of type or level of fat on pancreatic carcinogenesis	Male, 4 to 8-weeks-old, Syrian hamsters, 30 per group	84 weeks after BOP treatment	Control: 4.3% corn oil High corn oil: 20.5% corn oil Low beef tallow: 0.5% corn oil and 3.8% beef tallow High beef tallow: 0.6% corn oil and 19.9% beef tallow High mix: 5.1% corn oil and 15.4% beef tallow (as weight %)	Tumor inducer: BOP	Pancreatic ductular tumor and gall bladder and common duct tumor Pancreatic ductular tumor: Incidence and multiplicity of adenoma and adenocarcinoma, but not carcinoma in situ, was significantly higher (~2 times) in beef tallow than corn oil groups High fat (both corn oil and beef tallow) significantly increased carcinoma multiplicity in situ compared to low fat groups; however, fat level did not affect adenoma or adenocarcinoma multiplicity	The effect of the level and type of dietary fat differed with each of lesions of BOP-induced tumors examined The comparison of fat types might have been hampered by the fact that high or low beef tallow diets did not provide adequate linoleic acid for tumor development Caloric intakes were similar among groups The results in gallbladder or common duct tumor might have been weakened by the low

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Imaida et al., 1989 (Ref. 21)	The effect of high fat on lung tumorigenesis	Male, 6-week-old, ICR mice, 30 per group	25 weeks	Control: CRF-1 diet (3.5 kcal per g) High fat: 20% Corn oil supplementation to CRF-1 (4.7 kcal per g) Main Fatty acid composition(%) Control High fat oleic 22.4 32.8 linoleic 50.2 51.9 linoleic 4.6 1.8	Lung carcinogen: 4-nitroquinoline 1-oxide (NQO)	Lung: Corn oil supplemented high fat diet significantly enhanced incidence (80% versus 58%, high fat versus control) and yield (# tumor per mouse, 2.5 versus 1.2) compared to the control group	High fat (or high corn oil) in the diet significantly enhanced lung tumorigenesis in mice; however, diet composition, except main fatty acid was not reported There are apparent mistakes in the reported main fatty acid composition and we do not know the adequacy of linoleic acid in test diets Furthermore, nonisocaloric diets used and body weight gains were significantly different between groups which might have confounded the effect of fat level

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Katz and Boylan, 1989 (Ref. 22)	The effect of polyunsaturated fatty acid (PUFA) level on metastasis of transplanted mammary tumor	Female, aged virgin (14 to 16-month-old) or retired breeders (10 to 12-month-old), Fischer 344 rats, 12 per group	4 weeks before and 6 weeks after tumor transplant	High fat: 23% corn oil (4.59 kcal per g) Low fat: 5% corn oil (3.68 kcal per g) purina chow (6% fat)	13,762 rat mammary adenocarcinoma transplanted subcutaneously into just posterior to the 4th nipple	Pulmonary: High fat, fed either before or after the tumor implant, significantly enhanced pulmonary metastasis in rats (495 versus 135 mm^3, high fat versus low fat) This tumorigenic effect of high fat was abolished by previous feeding with chow diet; metastasis was comparable between chow and low fat groups	High fat (or high corn oil) in the diet significantly enhance pulmonary metastasis implanted from the 13,762 mammary tumor in rats; however, nonisocaloric diets were used Because energy intakes and body weight changes were not reported, energy-independent fat effect is not clear in the report

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Birt et al., 1989 (Ref. 23)	The effect of corn oil level on initiation and promotion of skin tumor	Female, 4-week-old, SENCAR mice, 30 to 40 per group	43 weeks	Corn oil 24.6 weight % 5.0 weight %	Tumor initiator: 12-O-tetradecanoylphorbol-13-acetate (DMBA) Tumor promoter: 12-O-tetradecanoylphorbol-13-acetate (TPA)	Skin papilloma: Incidence was not affected by fat level during DMBA period but promotion was significantly enhanced by high corn oil compared to low corn oil during TPA treatment period Final carcinoma yield (# per effective animal) was not affected by fat level	High fat (or high corn oil) diet significantly accelerated DMBA- and TPA-induced skin tumorigenesis in SENCAR mice The effect was evident during the promotion period, but not during the initiation period Because mice consumed similar energy by training, the effect of fat level was independent of the effect of energy or body weight changes
Borgeson et al., 1989 (Ref. 24)	The effect of fish oil on transplanted mammary tumor	Female, heterozygous BALB/cnu/+mice, 11 to 12 per group	32 days	Corn oil 10 weight % MaxEPA 10 weight %	Human mammary carcinoma MX-1, transplanted subcutaneously on the left side of each nude mouse	Mammary: Fish oil significantly depressed the growth (mg tumor yield) compared to corn oil	Fish oil depressed transplanted mammary tumorigenesis; however, the total fat level was very low and the fish oil diet did not provide adequate linoleic acid for growth of the host and tumor

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Fritsche and Johnston, 1990 (Ref. 25)	Whether n-3 fatty acid would affect transplanted mammary tumor growth and metastasis	Female, weanling, BALB/C mice, 10 to 15 per group	3 weeks prior to and 45 days to 13 weeks after the transplant	Corn oil 10 weight % Fish oil (menhaden oil and corn oil) at 10 weight % Linseed oil 10 weight % Corn oil 2% n-3 Fatty acid 53% n-6 Fatty acid Fish oil 24% n-3 Fatty acid 14% n-6 Fatty acid Linseed oil 56% n-3 Fatty Acid 18% n-6 Fatty Acid	BALB/cfc 3H mouse mammary tumor cell lines 410 and 410.4 (derived from spontaneously arising mammary adenocarcinoma) transplanted subcutaneously into the inguinal area of each mouse	Transplanted mammary tumor cells at inguinal area Different fat types did not significantly affect incidence of tumor; linseed oil, but not fish oil, significantly reduced the yield of tumor (weight) compared to corn oil Linseed and fish oil significantly reduced prostaglandin-E synthesis; fish oil reduced 410.4 tumor prostaglandin-E synthesis more than linseed oil, yet tumor growth was significantly inhibited only by linseed oil	The effects of n-3 fatty acid rich fish oil and linseed oil on transplanted mammary tumor growth were not consistent; however, fish oil and linseed oil might not have provided adequate linoleic acid for optimal tumor growth

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Adams et al., 1990 (Ref. 12)	The effect of fish oil on metastasis of transplanted mammary and lung tumor	Female, weanling, Fischer 344 rats, 15 per group	8 weeks before and 3 to 5 weeks after tumor transplant	Low fat: 5% corn oil High fat: 23.5% corn oil 8% corn oil and 15.5% fish oil 3% corn oil and 20.5% fish oil Fish Oil=Max EPA	13,762 NF mammary adenocarcinoma sublime (spontaneous model) was injected into thigh: 13,762 MAT:B ascites tumor cell sublime (experimental model) was injected into tail vein and grown in lung	Transplanted mammary and lung tumor 13,762 NF mammary tumor Levels or types of fat did not significantly affect incidence or growth 13,762 MAT:B lung tumor Low fat significantly inhibited the growth of the metastatic foci compared to high fat, high corn oil group 15.5% fish oil, but not 20.5% fish oil, significantly inhibited the growth of metastatic fish oil compared to high corn oil 20.5% fish oil significantly inhibit the growth of the metastatic foci compared to high corn oil, in one experiment, but not in another	The effects of corn oil level or fish oil level on metastasis of transplanted mammary or lung tumor were not consistent Diets might have provided adequate linoleic acid for growth of tumor; however, the fish oil level used were unrealistically high

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Sakaguchi et al., 1990 (Ref. 26)	The effect of n-3 fatty acid on human colon cancer cell lines inoculated into nude mice	6 to 8-week-old, BALB/c nude mice, 12 to 13 per group	4 weeks	Control: Low fat: 4.6 weight % lipids (chow diet) High saturated fatty acid (SFA): High fat: 19.2 weight % coconut oil and 0.8 weight % lipids High n-3 fatty acid: 19.2 weight % Max EPA and 0.8 weight % lipids % of n-6 fatty acid Control 12.7 High SFA 4.0 High n-3 fatty acid 2.5	Human colon cancer cell lines, COLO-320 or HT-29 were injected subcutaneously into dorsum of the chest wall	Transplanted colon tumor: fish oil significantly reduced (~50% reduction) volume and weight of tumor compared to the control and high SFA groups; there was no difference in tumorigenesis between the control and high SFA groups	High level of fish oil in the diet significantly suppressed the development of transplanted human colon cancer cells in mice; however, the test diets used might not have provided adequate linoleic acid for growth of tumor and the level of fish oil was unrealistically high Isocaloric diets were used and there was no differences in body weight changes among groups

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Deschner et al., 1990 (Ref. 15)	Combination of Max EPA with various levels of corn oil on colon tumor	Female, 5-week-old, CFI mice, 10 per group	2 weeks before and 48 weeks after azoxy-methanol treatment	16% corn oil and 4.4% Max EPA 10.2% corn oil and 10.2% Max EPA 4.4% corn oil and 16% Max EPA 20.4% corn oil 4.4% corn oil 4.4% corn oil was fed ad lib; the remaining diets were provided in controlled amounts as 40 g per cage per 2 days or 50 g per cage per 3 days to maintain body weights and reduce wastage	Azoxy-methanol	Colon: 4.4% fish oil diet group showed significantly higher incidence compared to 10.2% fish oil, 16% fish oil and 4.4% corn oil diet; there was no difference in incidence among 10.2% fish oil, 16% fish oil, and 4.4% corn oil groups 10.2% fish oil diet significantly reduced tumorigenesis compared to 4.4% fish oil diet (incidence: 30% versus 87.5%, # tumor per tumor bearing mouse: 1.3 versus 2.9) 16% fish oil diet did not affect incidence but significantly elevated tumor yield compared to 10.2% fish oil diet Compared to high corn oil diet, low corn oil diet significantly reduced the incidence (40% versus 63.3%): Effect of fat level on tumor yield was not significant	Biphasic response has been observed; 4.4% fish oil elevated, 10.2% fish oil suppressed, and 16% fish oil again elevated the tumorigenesis Corn oil level did not consistently affect the tumorigenesis Antioxidants were used

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Reddy et al., 1991 (Ref. 16)	The effect of n-3 rich fish oil and n-6 rich corn oil fed either during the initiation or/and during the postinitiation period on colon carcinogenesis	Male, 5-week-old, F344 rats, 39 per group	2 weeks before and 42 weeks after the treatment	Low corn oil: 5% corn oil High corn oil: 23.5% corn oil High fish oil: 18.5% menhaden oil and 5% corn oil	Azoxymethane	Colon: High corn oil diet, fed during the postinitiation period but not during the initiation period, significantly increased azoxymethane-induced tumorigenesis (incidence and multiplicity of colon adenoma and adenocarcinoma) compared to low corn oil diet High fish oil fed either during the initiation or the postinitiation period, significantly reduced azoxymethane-induced incidence and multiplicity of colon adenoma and adenocarcinoma compared to high corn oil; there was no difference in tumorigenesis between low corn oil and high fish oil diet groups	Azoxymethane-induced colon tumorigenesis in rats were significantly enhanced by high fat (high corn oil) diet and significantly suppressed by high fish oil diet; however, the fish oil level, tested, was unrealistically high Caloric intakes were similar among groups and there was no difference in body weight gains; therefore, the effect of corn oil level (total fat) was independent of energy effect

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
O'Connor et al., 1989 (Ref. 27)	The effect of n-3 fatty acid:n-6 fatty acid ratio on the development of pancreatic preneoplastic lesions	Male, 14-day-old, Wistar rats, 15 per group	4 months	Corn oil varied from 0 to 20 weight % menhaden oil varied from 20 to 0 weight % n3:n6 = 0.01 to 7.0 total fat = 20 weight %	Azaserine	Pancreatic tumor: Increased ratio of n-3:n-6 in the diet resulted in significantly decreased atypical acinar cell nodules (AACN) in the number and volume Type Oil: #AACN per cm^3: % vol of pancreas 20% corn oil: 632: 6.01 20% menhaden oil: 318*: 2.37* *Significantly different from the corn oil group There was significant, but unstable, regression between increased n3:n6 ratio and decreased AACN diameter More than 15 weight % menhaden oil (less than 5 weight % corn oil) in the diet did not further suppress the AACN development High menhaden oil significantly decreased serum prostaglandin-thromboxaneB_2, prostaglandin-E_2 and 6-Keto-prostaglandin-$F_{1\alpha}$	Preneoplastic lesion, not tumor, was tested Because less than 5 weight % corn oil (more than 15 weight % menhaden oil) in the diet did not affect the tumorigenesis, 5 weight % of n-6 fatty acid rich corn oil may be required for optimal tumorigenesis The results suggest that high n-3 fatty acid in the diet may suppress the development of azaserine-induced preneoplastic lesion of the pancreas in rats Isocaloric diets were used, and there were no differences in body weight changes among groups

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Orengo et al., 1989 (Ref. 28)	The effect of menhaden oil on photocarcinogenesis in hairless mouse	4 to 5 1/2 month-old, 40 SKH-Hr-1 mice, 40 per group	2 weeks before and 20 weeks after ultraviolet radiation	Corn oil 0.75 weight % 4 weight % Menhaden oil 4 weight % 12 weight % total fat = 0.75 - 12 weight %	Ultraviolet radiation	Skin: 12% menhaden oil significantly prolonged latency period compared to 4% menhaden oil, 4% corn oil, or 0.75% corn oil 4% menhaden oil significantly prolonged latency period compared to 4% corn oil, but not 0.75% corn oil 12% menhaden oil significantly suppressed multiplicity compared to 4% corn oil, but not 4% menhaden oil or 0.75% corn oil 4% menhaden oil significantly suppressed multiplicity compared to 4% corn oil, but not 0.75% corn oil Latency (med. tumor time, week) / Multiplicity (# tumor per animal at 20 week) Corn oil 4% 19.0[A] 1.43[D] 0.75% 21.9[B] 0.47[E] Menhaden Oil 4% 23.2[B] 0.41[E] 12% 26.1[C] 0.23[E] Different letter as a superscription shows a statistically significant difference	n-3 fatty acid-rich fish oil in the diet significantly suppressed the development of ultraviolet radiation-induced skin tumorigenesis in mice; however, the test diets, except 4% corn oil, might not have provided adequate linoleic acid for growth of tumor and the host animal Total fat level was very low Iso caloric diets used

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Locniskar et al., 1990 (Ref. 29)	The effect of fish oil on skin tumorigenesis	Female, weanling SENCAR mice, 30 per group	4 weeks initiation period and 42 weeks promotion period	(wt%) Menhaden oil / Corn oil / Coconut Oil 0 / 1.5 / 8.5 1 / 1.5 / 7.5 4 / 1.5 / 4.5 8.5 / 1.5 / 0 0 / 10 / 0 Total fat 10 weight %	Initiator: 7,12-dimethyl benz(a) anthracene (DMBA) Promoter: 12-0-tetradecanoyl phorbol-13-acetate (TPA)	Skin: No differences in the incidence of papilloma or carcinoma, and in the multiplicity among groups	Fish oil was not protective in the DMBA- and TPA-induced skin tumorigenesis in mice; however, test diets, except 10% corn oil, might not have provided adequate linoleic acid for tumor growth The total fat level was very low Caloric intake, food consumption, and body weight changes were similar among groups
Yam et al., 1990 (Ref. 30)	The effect of n-6 fatty acid:n-3 fatty acid ratio on transplanted tumors	Male, 26 to 30-weeks-old, C57BL/65 mice, 30 per group	12 to 16 days	Soybean oil 4 weight % Linseed oil 4 weight % Fish oil 4 weight %	Transplant of EL4-lymphoma cells (insulin producing cells) or thymoma cells (insulin-dependent cells) into right flank muscle	Transplanted lymphoma and thymoma cells In EL4 mice, linseed oil, but not fish oil, significantly suppressed the growth of tumor (weight) compared to the soybean oil group In thymoma mice, fish oil, but not linseed oil, significantly suppressed the growth of tumor compared to the soybean oil group	Test diets contained unrealistically low total fat and the findings cannot be extrapolated to normal human physiology Furthermore, linseed oil and fish oil diets might not have provided adequate linoleic acid for tumor growth

Table 1--continued

Reference (author, date)	Objective	Test animals	Duration of Study	Diet	Additional Treatment	Results	Assessment
Ling et al., 1991 (Ref. 31)	The effects of fish oil and medium-chain triglyceride in parenteral nutrition regimen on transplanted tumor	Male, Sprague-Dawley rats (age not reported), 90 to 100 g, 10 per group	11 days	Control: Intralipid containing 2.4 weight % lipids Test: 2.6 weight % fish oil with medium-chain triglyceride of 40% fish oil: 60% medium-chain triglyceride	Transplant of Yoshida Sarcoma cells by subcutaneous injection Intravenous tumor necrosis factor (TNF)	Transplanted Sarcoma cells The replacement of long-chain fatty acid with fish oil of medium-chain triglycerides in the TPN solution significantly inhibited tumor growth as volume, but not as w	Fish oil with medium-chain triglyceride TPN regimen did not provide adequate linoleic acid for growth of the host animal and tumor

Dietary Lipids and Cancer: Human Studies 1988-April 1991

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Prentice et al., 1988 (Ref. 37)	Ecologic; 21 Countries: 45 to 69 year old Women	To offer explanations for international variations in breast cancer rates	Food disappearance data rather than actual food intakes are used to estimate per capita consumption	Breast cancer	Breast cancer incidence was strongly correlated with national estimates of per capita intake of dietary fat, but not with other calorie sources (protein and carbohydrate) There was a weak correlation for total calories ($p = 0.09$) Total calories alone explained only 14% of the variation in breast cancer incidence compared with 58% for fat calories alone When fat and other sources of calories are entered simultaneously into regression analysis, fat calories remained highly significant ($p = 0.0004$) with unchanged regression coefficient Nonfat calories were not significant ($p = 0.88$)	Ecological studies all suffer from ecological fallacy Comprehensive controlling of confounding factors is not possible In this study, adjustment for other dietary factors - total calories was done by regression Because food disappearance data was used, more affluent countries would incorrectly show higher consumption, reflective of higher waste

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Hursting et al., 1990 (Ref. 38)	Ecologic: Registry data in 20 countries for 35 to 64 year olds	To test the hypothesis that different kinds of fatty acids have different tumor-promoting capabilities	Per capita dietary intakes were obtained form food balance sheets for 1975 to 1977 and assessed by a multiple regression analysis	Breast, cervix, lung, colon, and prostate	The incidence of breast cancer was significantly associated with intakes of total fat (r=0.72), Saturated fat (r=0.57), n-6 polyunsaturated fat (n=0.5), but not with monounsaturated fat or n-3 polyunsaturated fat The incidence of female colon cancer was significantly associated with intakes of total fat (r=0.62) and saturated fat (r=0.47), but not with polyunsaturated fat, monounsaturated fat, n-6 polyunsaturated fat, or n-3 polyunsaturated fat The incidence of prostate cancer was significantly associated with intakes of total fat (r=0.69), saturated fat (r=0.55), and polyunsaturated fat r=0.46), but not with n-3 polyunsaturated fat; n-6 polyunsaturated fat intake showed a borderline association (r=0.46, p=0.074) The incidence of both cervical and lung cancer was not significantly associated with any type of fat intake or total fat intake Total calorie intake was not associated with cancer at any site when controlled for total fat intake	Dietary assessment: Dietary fat consumption disappearance increases with social and economic development and may simply be a marker for affluence, which would affect the incidence figures for cancers, such as improved cancer detection W-3 polyunsaturated fat intake among the populations was relatively small and invariable Confounding: All regression analyses were adjusted for age and intakes of all other component fats as well as for total calories As is the case with all ecologic studies, because populations, rather than individuals are measured, associations may be spurious Comprehensive controlling of confounding factors is not possible Correlations were reported only for female cancers and male prostate cancer; results reported to be similar for males were not shown

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Kneckt et al., 1990 (Ref. 39)	Prospective; 20 year followup; 3,988 initial cancer-free Finnish women aged 20 to 69 years From 30 different regions of Finland: 54 cases were identified	To examine the relationship between dietary fat and breast cancer	Examined role of total fat, saturated fatty acid (SFA), monounsaturated fatty acid (MUFA), polyunsaturated fatty acid (PUFA), cholesterol intakes, and energy intake through dietary history	Breast Cancer	The overall relative risk (RR) for the association between relative fat intake and occurrence of breast cancer is: Overall RR 1.7 (0.6-4.8)* SFA intake 1.4 (0.5-3.7)* MUFA intake 2.7 (1.0-7.4)** PUFA intake 1.2 (0.6-2.8)* Cholesterol intake 2.2 (1.0-5.0)** * = Nonsignificant ** = borderline significant Breast cancer is inversely associated with energy intake, but not significantly related to fat intake	Method of dietary assessment: Dietary history was collected 20 years prior up to diagnosis, so recall bias is eliminated However, changes in diet over the 20 year followup interval were not evaluated Dietary confounders: Adjustment was made for total energy intake Confounders: Adjustments were made for age, body-mass index, stature, smoking, parity, menopausal status, and rural versus urban geography

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Howe et al., 1991 (Ref. 40)	Prospective study; 5 year followup period (1982-1987); 56,837 women, 40 to 59 years enrolled in the Canadian National Breast Screening study; 519 breast cancer cases were identified during the followup	To examine the relationship between energy sources and breast cancer risk	The self-administered diet-history questionnaire on 86 food items; and an interview-administered dietary history; subjects had completed the dietary questionnaire before diagnosis	Breast cancer	Except for the lowest quartile, there was a significant association between increasing fat intake and the incidence of breast cancer (RR for the highest quartile=1.3 : 95% HIGHEST =1.00-1.82) All three fat types (SFA, MUFA, and PUFA) showed a general pattern of increasing risk of breast cancer with increasing intake The exceptions were the first quartiles for SFA and MUFA (The mean % of calories from fat was 31% and 47% for the lowest and highest quartiles, respectively) Menopausal status did not affect the results	Dietary measure: Comparison of the results from the interview-administrated dietary history and the self-administered dietary history showed good validity and reliability Subjects had completed the dietary questionnaire before diagnosis, eliminating recall bias Confounders in diet: The association between fat intake and risk was assessed after adjusting for other sources of calories Total calorie intake was not associated with increased risk Adjusted for education, age at menarche, age at first pregnancy, nuliparity, surgical menopause, age at menopause, history of benign breast disease, and breast cancer in first degree relatives

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Mills et al., 1988 (Ref. 41)	Nested case-control; 142 fatal breast cancer and 852 age-matched controls among CA Seventh-day Adventist women from 1960 to 1980; 30 to 85 years; whites	To test the hypothesis that breast cancer mortality is related to the usual frequency of use of specific foods of animal origin, including meat, cheese, milk and eggs	A 21-item food frequency questionnaire	Breast	No significant relationship between the consumption of animal products (meat, milk, cheese, eggs) and breast cancer risk Among women with relatively early age at menopause (≤ 48 years), a suggestive but nonsignificant, positive association between meat consumption and the risk of breast cancer was noted	Although there was significant variation in the frequency of meat consumption between cases and controls, both groups were low meat consumers by American standards: 47% of the total population never or only occasionally consumed meat Dietary measure: The 21-item food frequency questionnaire was not sufficiently detailed to allow analysis of specific nutrients; therefore, the consumption of fat specifically was not tested for its relationship with the risk of breast cancer

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Rohan et al., 1988 (Ref. 42)	Case-control: 451 female Australian case-control pairs; 20 to 74 years old; Cases were with first diagnosis with breast cancer 1982 to 1984 Controls were without a history of breast cancer; randomly selected from the electoral roll; age matched with the case 113 premenopausal pairs and 262 postmenopausal pairs The remainders were either premenopausal or discordant on menopausal status	To test the hypothesis that the risk of breast cancer increases with increasing intake of total fat, protein, and energy; and decreases with increasing intake of vitamin A	A 179 food item, self-administered food frequency questionnaire; cases were instructed to disregard any dietary changes that had occurred subsequent to their diagnosis of breast cancer	Breast	No significant association between dietary intake of fat, energy, protein, or carbohydrate and breast cancer risk	Dietary measure: Instructing the cases to disregard dietary changes subsequent to their diagnosis of breast cancer may have helped eliminate some of the recall bias The range of total fat intake among the total population was 35% versus 46% in the lowest versus highest quintile of fat intake Dietary fat intake in this population may not be sufficiently heterogeneous to detect variation in disease risk Dietary confounders: The difference in fat intakes between the cases and the controls was not reported Energy intake was not adjusted in the risk analysis for lipid intake

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Gerber et al., 1989 (Ref. 43)	Case-control: Hospital-based population of French women 25 to 65 years; Cases: 120 with a first diagnosis of breast cancer Controls: 109 with admission for neurologic syndromes of other than cardiovascular or tumoral origin, or for lumbalgias or disc pathologies	To address the question of the specific role of fatty acids in relation to breast cancer	Nutritional data from a questionnaire on the dietary history: Weekly or monthly frequency of consumption for 55 key food items in lipid and vitamin consumption	Breast	Pre-menopausal and postmenopausal groups considered separately Intakes of total lipids, SFA, MUFA, PUFA, and olive oil were greater in cases than in controls (borderline-significance: p=0.07) Intakes of sunflower oil was greater in cases Fatty acid serum distribution is comparable in both samples, except arachidonic acid, which is significantly lower in premenopausal patients than in premenopausal controls Plasma lipid peroxidation is significantly lower in patients than controls	Major confounding factor: The association between calcium and decreased peroxidation can be fortuitous or reflect the decreased rate of lipid peroxidation association with an increased rate of cell division The authors admit that the fat intake result is controversial and have undertaken a larger case-control study

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Toniolo et al., 1989 (Ref. 46)	Case-control: Cases: 250 women with breast cancer, but no metastases; Controls: 499 women from a randomized, stratified sample of the general population All < 75 year old and from the Vercelli province in Italy	To investigate the role of diet in breast cancer	An interviewer-administered dietary history questionnaire	Breast	Cases consumed more calories (2,419 vs 2,294 kcal per day) and total fat (94.4 vs 88.2 g per day) compared to the control Age and calorie-adjusted relative risk showed a significant association for SFA intake (p=0.001) and total fat intake (p=0.056) The intake of dairy products was significantly associated with the risk of breast cancer Neither meat consumption nor poultry consumption significantly increased the risk	Well-done study; Dietary assessment: Questionnaire had been tested previously, validated, and used in a study with, which produced comparable results Variation of fat intake in diet is 26% to 46% in this study, as opposed to only 32 to 44% in Willet's Confounding for nondietary risk factors: Adjusted for age at menarche, age at menopause, age at first birth, height, weight, Quetelet index (weight divided by height squared), socioeconomic status, and martial status
Ewertz and Gill et al., 1990 (Ref. 47)	Case-control: 1,486, breast cancer cases diagnosed over a 1 year period in Denmark; <70 year 1,336 age-stratified random sample from the general population as the control	To elucidate the influence of dietary factors and hormones on breast-cancer risk	Self-administered questionnaire, given 1 year after the diagnosis: the semi-quantitative food-frequency questionnaire collected food intake data for the year prior to diagnosis for 21 food items	Breast	Total fatty acid intake was significantly and linearly associated with breast cancer risk (RR for the highest quartile=1.45; p<0.001 for the test of a trend)	Dietary measure: The 21 food item included in the questionnaire covers about 80% of fat consumption The questionnaire was designed with two global questions to monitor the frequency of consumption of meat and vegetables The sum of the frequencies of consumption was compared with the global frequency and weights were assigned to adjust overestimations Confounders: Effect of energy intake was not controlled

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Mettlin et al., 1990 (Ref. 48)	Case-control Cases: 3,334 men and women (50% of each); ages 19 to 97 years Controls: 1,300 men and women, hospital-based	To test the hypothesized positive association between fat and cancer, and hypothesized inverse association between cancer and vitamin A, D, riboflavin, and calcium	Dietary questionnaire for milk-drinking habits	oral, stomach, colon, rectum, lung, Breast, uterus, cervix, prostate, bladder	Controls were more likely to never drink whole milk than cases, after adjusting for sex, age, smoking, education and county of residence Findings were significant only when comparing whole milk to no milk (reference group) and for the oral cavity, stomach, colon, rectum, lung, bladder, prostate and breast	This study is of little value because it does not address the correlation of milk intake with dietary fat intake Many other factors which may be associated with milk drinking habits were not controlled Biases inherent in hospital based sample
Boyd et al., 1988 (Ref. 54)	Randomized clinical trial; 295 women with ≥ 50% of the breast volume occupied by mammographic dysplasia; ≥ 30 year (mean age 44), (147 control and 48 intervention): 5% of the control group and 20% of the treatment group lost during followup; 76% of subjects premenopausal	To determine (1) if long-term compliance with a low fat diet can be achieved and (2) if mammographic dysplasia increases one's risk of breast cancer	Dietary advice: Control group to maintain healthy diet without changing dietary fat intake Intervention group to reduce fat intake to 15% of the calories A 3-day food record and a 1-day dietary recall	Breast cancer	(1) Combined control and intervention groups experience higher cancer than expected in the general population (2) Dietary compliance was maintained over the 1-year intervention period	This study is important as an precursor for future intervention trials; it tells us that compliance is possible for at least 1 year, and it supports the hypothesis that mammographic dysplasia is a high risk factor in breast cancer development However, the time is too short and the numbers too small to draw any conclusions about dietary fat and the incidence of breast cancer

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Verreault et al., 1988 (Ref. 55)	Survey of 666 women with a newly diagnosed infiltrating breast carcinoma 1982 to 1984; Quebec City area, Canada	To study the possible effect of diet on the progression of breast cancer, once it has occurred	An interviewer administered food frequency questionnaire covering 114 food items for the year preceding diagnosis	Breast	After the adjustment for energy intake, total fatty acid intake showed no association with the frequency of nodal development after diagnosis After adjusting for energy intake, age, body weight, and tumor size, the intake of SFA was not significantly associated with the frequency of axillary node development at diagnosis among post-menopausal patients PUFA intake was negatively and significantly associated with nodal development	Dietary measures: The type of PUFA is not identified The study assessed a growth of nodes (proxy for progression of the disease), but not directly the risk of cancer
Boyd et al., 1989 (Ref. 56)	Case-control; 30 women with extensive mammographic dysplasia (≥ 75% of the breast involved) and 16 women without dysplasia (≤ 25% dysplasia); 30 to 50 years; Breast center at Women's College Hospital and National Breast Screening Center at the Mt. Sinai Hospital	To determine biochemical associations with mammographic dysplasia	A 7-day recall plus a 4-day food record	Breast	No significant difference in consumption of total fat, different types of fat, cholesterol, total calories, carbohydrate, or protein for those with and without dysplasia	Dietary concerns: There may be an insufficient difference in nutrient intake between the two groups to detect an effect Confounders: Because the study's objective was to determine plasma lipid levels, dietary fat was examined as a confounder for lipid plasma levels - the study did not examine for confounders of dietary fat intake

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Eid and Berry et al., 1988 (Ref. 52)	Case-control; 85 Israeli women (ages not given) who were undergoing biopsies for breast masses 37 had carcinoma, 27 had fibroadenoma, 21 had other types of masses	To study the effects of the quality of fat (i.e., saturated versus polyunsaturated) and carcinogenesis	Dietary measures not necessary; fatty acid composition measured directly through biopsy Breast tissue from each individual was analyzed for fatty acid composition (16 also had adipose tissue biopsied from buttocks to compare breast tissue fat as an indicator for overall subcutaneous body fat: 98% correlation)	Breast	The quality of dietary fat does not appear to be associated with the development of neoplasia of the breast: Fiber-adenoma Other Cancer PUFA:SFA Ratio 0.99 0.98 1.03 The PUFA:SFA ratio was no different between the group with cancer, fibroadenoma, or other tumors	Age is a possible confounder However, an analysis of 400 biopsies revealed insignificant correlation between age and polyunsaturated to saturated ratio All subjects are patients with breast lesions Data was reported only as a ratio for tissue fatty acids; the actual amount is important as well
Brisson et al., 1989 (Ref. 57)	Case-control; 290 newly diagnosed breast cancer patients and 645 women who participated in the Canadian National Breast Screening Study as the control; 40 to 62 year; in Quebec	To evaluate the association of the morphology of breast tissue seen on mammograms with breast cancer risk and to assess the relation of diet, especially intake of fat and vitamin A, to the high-risk mammographic images	An interviewer-administered food frequency questionnaire of intake of 114 food items during the previous year	Breast Cancer	Among controls, energy adjusted intakes of saturated fat, but not polyunsaturated fat or cholesterol was significantly associated with an increase in extent of high-risk mammographic features The risk of breast cancer incidence increases regularly with the extent of modular and homogeneous densities on the mammogram	Dietary measure: acceptable; suffers recall bias Confounding: adjusted for age, weight, parity, and education Fiber intake was measured and considered separately in analysis

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Pryor et al., 1989 (Ref. 45)	Case-Control; white females between the ages of 20 and 54; 172 cases are women who were diagnosed with histologically confirmed first primary breast cancer 190 matched controls	To assess how intake of dietary fat and fiber during adolescent years is related to the incidence of breast cancer	Used National Cancer Institute food frequency questionnaire to assess past intake during adolescent years	Breast Cancer	Stratified on groups High fat intake consistently lowered the odds ratio (OR) below 1.0 in premenopausal women, but not significantly (OR = 0.7, confidence interval (CI) = 0.2-2.1 for highest versus lowest quartile) The relationship was inconsistent and not significant in postmenopausal women (OR = 0.7. CI = 0.2-2.7 for highest versus lowest quartile) The relation of breast cancer to dietary intake during adolescence is not clear	Dietary measure: Very long recall period, producing bias Controlling: Done for age, education, age at first pregnancy through multiple logistic regression Fiber intake adjusted in analysis Fat from dairy products considered separately from other sources

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Holm et al., 1989 (Ref. 53)	Case-control; 240 women 50 to 65 years who had surgery for breast cancer (1983-1986); mainly post- menopausal	To examine the relationship between dietary habits and prognostic factors for breast cancer	A dietary history interview within 4 months after resection of the primary tumor for prediagnostic food consumption	Breast cancer	Patients with tumors ≥ 20 millimeter (mm) in diameter had significantly higher mean percent energy from total fat and monounsaturated fat, and significantly lower mean energy from carbohydrates compared to patients with tumors < 20 mm; there was no significant difference in the total energy intake mm Tumor size < 20 > 20 p Total energy, energy % 36.3 38.1 0.02 Monounsaturated fatty acid energy % 12.4 13.2 0.003 Carbohydrate energy % 46.3 44.6 0.06 Total energy in millijoules 8.2 7.8 Nonsignificant	Poor study due to lead-time bias: Timing not corrected for the women who have surgery earlier (more routine care, self-exam, better diets, etc.) Adjustment was made for fiber, carbohydrates, and total energy

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Iscovich et al., 1989 (Ref. 44)	Case-control; 150 women with breast cancer, diagnosed 1984 to 1985, 0 to 75 year mean 56 year; controls: for each case, one hospital control, matched by age and hospital, and one neighborhood control, matched by residential area and age	To uncover associations between diet and breast cancer	An interviewer-administered semiquantitative food frequency questionnaire on 147 food items during the 5 year period up to 6 months prior to interview	Breast cancer	Intake of energy total fat, protein, and carbohydrates were significantly associated with the risk of breast cancer Intakes of processed meat, fried meat, animal fat, eggs, grains, and pulses were significantly associated with the risk of breast cancer Intakes of fruit and vegetables were negatively associated Intakes of red meat, poultry, and vegetable oil were not significantly associated	Confounders: Adjustment for education, age, age at first pregnancy, and parity Adjustment for total calorie intake was not done No significant difference was found between the effects of fat, protein, and carbohydrates
Boyd and McGuire 1990 (Ref. 58)	Case-control; 30 women with extensive mammographic densities (≥ 75% dysplasia) and 16 controls without radiological changes (<25% dysplasia); 30 to 50 years	To determine if mutagenic products generated by lipid peroxidation may influence breast cancer rate	4 day food record	Breast cancer	The group with extensive mammographic dysplasia excreted twice the amount of malonaldehyde int the urine compared to the control group ($p<0.02$) The quantity of malonaldehyde in the urine is an indicator of lipid peroxidation in diet or tissue No difference in nutrient intakes including total fat between the two groups	Because the main objective of this study was to examine malonaldehyde, fat was just one of the selected variables considered for confounding Confounding for fat was not considered here

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Simard et al., 1990 (Ref. 49)	Case-control: 68 women with breast cancer age-matched and 343 women as the control; 40 to 49 year; in Montreal	To compare fibrocystic patients with age-matched controls selected within the same cohort population of women attending the Canadian National Breast Screening Study (NBSS)	A semiquantitative food-frequency questionnaire for the breast cancer patients A 24 hour dietary recall for the control subjects	Breast	The breast cancer patients consumed significantly more poultry, fish, pastry, and margarine; and, less milk and butter	Dietary Assessment: The method for collecting food consumption was different between the control and the cases The risk was assessed with current food consumption while it was noted that 16% of cancer patients had been on a reducing diet
Vaint Veer et al., 1990 (Ref. 50)	Case-control: 133 newly diagnosed breast cancer cases; 25 to 44 year (98% premenopausal) or 55 to 64 year (97% postmenopausal); 289 age-stratified healthy controls from general population; Netherlands	To design and carry out a study which examines the role of dietary fat in breast cancer, but overcomes problems of many other studies; specifically, methodological problems in dietary assessment and confounding by energy intake is corrected through the use of a standardized and reproducible dietary history technique	A 236 food item diet history interview was conducted to cover the dietary pattern in the 12-month period prior to diagnoses or the interview date	Breast	Age-adjusted dietary fat intake in breast cancer cases was significantly higher than that in healthy controls (120 vs 92 g) The age-adjusted OR showed a significant positive trend with increasing fat intake The multivariate adjusted OR was 3.5 for subjects in the highest quintile of fat intake compared to those in the lowest quintile The OR, adjusted for energy intake and age, was 1.54 per 24 g fat or 10% fat energy Intake of each type of fat (SFA, MUFA, PUFA) was positively associated with the risk as well	Dietary Measure: Reproducibility of the questionnaire was verified by a repeated measurement one year after in 39 control subjects Confounding by Nondietary factors: Adjustment was made for familial history, history of benign breast disease, education, employment, age at menarche, age at first full-term pregnancy, parity usage of oral contraceptives, smoking, body mass index, and alcohol intake

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Van't Veer et al., 1991 (Ref. 51)	Case-control: Newly diagnosed 133 women breast cancer cases and 289 population controls in the Netherlands; 25 to 44 and 55 to 64 year	To examine several combinations of dietary factors - total fat, fermented milk products and fiber on breast cancer occurrence because these dietary factors are hypothesized to alter estrogen metabolism by the intestinal microflora	A 236 food item, interviewer-administered diet history questionnaire; Dietary pattern in the 12-month period prior diagnosis	Breast	Dietary fat intake was positively associated with the risk of breast cancer after adjustment for age (OR=0.57; CI=0.36-0.90) When total fat is included as a main effect, fiber, fermented milk and total fat produce an interactive effect which is positively associated with the risk (OR=0.33; 0.15-0.73)	Dietary method: Most cases were interviewed within 6 months after diagnosis Energy intake was not adjusted Nondietary confounders considered: Age, alcohol intake, history of benign breast disease, familial history, smoking, educational level, oral contraceptive use, age at menarche, parity, body mass index and geographical area

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Willett et al., 1990 (Ref. 62)	Prospective; 88,751 registered nurses; 34 to 59 year; no history of cancer, inflammatory bowel disease, or familial polyposis; 150 colon cancer cases were documented during the 6-year followup (1980-86)	This is part of the Nurses' Health Study Cohort Its objective is to determine risk factors for cancer and coronary heart disease	A 61 food-item, interviewer-administered, semi-quantitative food frequency questionnaire focusing on fat and fiber foods was used The dietary interview was done in 1980	Colon	Total energy intake or body-mass index was not associated with the incidence of colon cancer Age and energy-adjusted intakes of total fat, animal fat, SFA, and MUFA were significantly associated with the incidence of colon cancer; intakes of vegetable fat, linoleic acid, and cholesterol were not RR C.I. Total fat 2.0 1.1-3.6 Animal fat 1.9 1.1-3.2 SFA 1.4 0.8-2.3 MUFA 1.7 1.0-2.9 Strongest associations with beef, pork, or lamb eaten as a main dish; daily eaters had 2 1/2 times the risk of those less than once a month eaters (P for trend = 0.01) Consumption of whole milk, cheese, and ice cream was not significantly related to the risk	Dietary assessment: The dietary method was validated by comparing its results with results of one-week weighed food record method in a random cohort Since the interview was done in 1980, prior to disease development, there is no recall bias Controlling dietary factors: Controlling for physical activity did not alter the association of the intake of animal fat or meat with the risk Energy adjustment was done

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
La Vecchia et al., 1988 (Ref. 66)	Case-control: 339 cases of colon cancer and 236 cases of rectal cancer; both sexes; 1985 to 1987; median ages, colon cancer = 61 year, rectal cancer = 62 year; northern Italy 776 controls; both sexes; median age = 58 years The controls were also patients admitted to hospital for acute, nonneoplastic or digestive disorders	To examine the relationship between diet and colorectal cancer in a population in which there is good heterogeneity in dietary consumption	A 29 food item interviewer-administered food frequency questionnaire on food consumption prior to diagnosis	Colon and rectal	Age and sex adjusted consumptions of beef or veal and pasta or rice were significantly associated with the risk of colon and rectal cancer Age and sex adjusted consumption of butter and olive oil, but not margarine, was significantly associated with the risk of colon cancer but not the risk of rectal cancer	Dietary method: Energy consumption was not adjusted in the data analysis Frequencies, but not quantities of food consumption were analyzed Confounding of nondietary factors: Adjustment was made through multiple logistic regression for age, sex, social class, and area of residence
Neoptolemos et al., 1988 (Ref. 59)	Case-control: Cases: 30 men and 19 women, between the ages of 49 and 92, with colorectal cancer Controls matched for age and sex	To assess the erythrocytic fatty acid profile in a relatively homogenous group of patients with cancer of the colon and rectum, using closely- matched controls	Fatty acids were determined in erythrocytes and adipose tissue An interviewer-administered 7-day dietary recall during hospitalization on the day before surgery	Colorectal	Marginally increased levels of stearic acid ($p<0.06$) and oleic acid ($p<0.06$) and decreased arachidonic acid ($p<0.04$) in cancer patients Marginally increased levels of stearic acid ($p=0.06$) and oleic acid ($p=0.06$) and decreased arachidonic acid ($p=0.04$ occurred in cancer patients These findings indicate a disturbed fat metabolism in cancer patients	The study did not address the association of diet intake and the risk of cancer

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
West et al., 1989 (Ref. 61)	Case-control: 231 colon cancer patients and 391 population controls Both sexes; 40 to 79 year; whites; 1979 to 1983 in Utah	To evaluate the role of fiber and fat ingestion on colon cancer development, as well as to study the associations between intake of energy, types of fat, protein, vitamins A and C, and cruciferous vegetables and the disease	A 99 food item interviewer-administered, food frequency questionnaire for 2 to 3 years prior to the interview; over 90% of foods eaten by Utah residents	Colon	Both in females and in males, total fat intake was significantly associated with the risk (OR=1.9 in females and 2.0 in males. in the highest quartile) Intakes of different types of fats (MUFA, SFA, PUFA) were not consistently associated with the risk	Dietary analysis: recall bias; omitted data due to physician's refusal (23 of 324 cases), patient's refusal (70 of 324), death before the interview (53 of 324) Dietary confounders: Adjustment of data by multiple logistic regression for fiber and body mass index; energy intake was not controlled in the data analysis
Benito et al., 1990 (Ref. 67)	Case-control: 286 colorectal cancer cases, 295 population controls, and 203 hospital controls; Majorcan residence; mean age and was 64 year both sexes	To investigate the role of dietary factors in the etiology of colon and rectum cancer	A 99 food item interviewer-administered food frequency questionnaire for average consumption for the previous year	Colorectal	A significantly increased risk of colon cancer was found for consumption of fresh meats (RR=2.87) while consumption of cruciferous vegetables afforded protection (RR=0.48) Consumption of dairy products significantly increased the risk of rectal cancer but not the risk of colon cancer Consumption of oil was not associated with the risk of colon or rectal cancer	Dietary survey: The average interval between diagnosis and interview was relatively short, 3 months Adequacy of controls: The results were reported by comparisons with the population controls only Adjustment of confounders: Age and sex, but not energy intake were adjusted in the data analysis

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Ghadirian et al., 1991 (Ref. 63)	Case-control: 179 pancreatic cancer patients in Greater Montreal from 1984 to 1988; 35 to 79 year; both sexes 239 population-based, age, sex, and place of residence matched controls	This study was a subset of the SEARCH collaborative Study Group for the case-control study of cancers of the pancreas, bile ducts and gallbladder of the International Agency for Research on Cancer	A more than 200 food-item and beverage, interviewer-administered food frequency questionnaire was used	Pancreatic	After adjustment for age, sex, energy intake, response status, and cigarette consumption, total fat intake (OR=2.24) and SFA intake (OR=4.32) were significantly associated with the risk of pancreatic cancer	Dietary intake measurement: 25% of the cases and 83% of the control were interviewed directly; 75% of the cases and 17% of the control were interviewed by proxy Confounders: Adjustments made for age, sex, energy intake, response status, and cigarette consumption
Goodman et al., 1988 (Ref. 64)	Case-control: 226 men and 100 women with lung cancer; 597 men and 268 women population-based controls, sex and age matched to the cases; five ethnic groups in Hawaii; 30 to 84 years	The specific objective of this study was to test the effects of dietary fat and cholesterol on lung cancer	An interviewer-administered diet history questionnaire on food consumption for a usual month prior to diagnosis; the food items would provide ≥ 85% of the intakes of cholesterol and fat	Lung	Intakes of total fat SFA and MUFA were significantly higher in the cases compared to the controls in men, but not in women; in women, only the same tendencies were found (nonsignificant) Cholesterol intake was significantly associated with the risk in smoking men (OR=2.2), but not in women or past smokers; the association was consistent for three of four ethnic groups analyzed separately	Dietary measurement: Among cases, 28% of men and 32% of women were interviewed by proxy Among controls, 6% of men and 7% of women were interviewed by proxy Dietary confounders: Fat intake was not adjusted in the assessment of cholesterol and the risk association; cholesterol was not adjusted in the assessment of fat intake and the risk association Adjustment for other confounders: Adjustments for age, ethnicity and cigarette smoking

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Franceschi et al., 1989 (Ref. 68)	Case-control: 208 nonHodgkins lymphoma cases and 401 control subjects who were in the hospital for acute, nonimmunologic or neoplastic conditions; men and women; 18 to 80 year; northeastern part of Italy	The role of various lifestyle factors, including dietary habits, was investigated in the etiology of nonHodgkins lymphoma	Food frequency questionnaire including 14 food items or groups of foods and 7 beverages	Lymphoma: NonHodgkins lymphoma is a heterogeneous group of disorders resulting from malignant transformation of lymphoid cells	The consumption of butter and oil was positively related with NonHodgkin's lymphoma risk The consumption of milk also was positively related with the risk The consumption of meat or fish was not related with the risk	Dietary survey: The questionnaire method was verified by a repeated telephone survey on a subpopulation Selection of controls: The controls were also hospitalized patients Confounders: The data was presented after adjustment for age and sex, but not for total fat or energy intakes
Steineck et al., 1990 (Ref. 65)	Case-control: 323 urothelial cancer cases in Stockholm, Sweden during 1985 to 1987 and 392 population-based controls selected by gender and age stratified random sampling	To investigate the association between urothelial cancer and dietary factors, with special reference to vitamin supplements, dietary vitamins, and fried foods	A 56 food-item food frequency questionnaire; recall dietary habits 3 years prior to interview	Urothelial	A dose-response relationship was seen with an increasing intake of fat (RR=1.7 in the highest quintile) and the risk Adjustment for fried foods, in addition to gender, age, and smoking decreased the relative risk (RR=1.3 in the highest quintile) No association was noted for meat other than fried meat	Dietary measure: long recall period, inadequacy of the questionnaire to analyze fat intake Dietary confounders: failure to adjust energy intakes Other confounders: Adjustment made for gender, age and smoking

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Franceschi et al., 1991 (Ref. 69)	Case-control: 302 oral cavity and pharynx cancer cases and 699 controls admitted to hospital for acute, nonneoplastic, and non-digestive disorders; in Pardonone province, northeast Italy	To examine the relationship between dietary indicators and the risk of cancer of the oral cavity and pharynx	A 40 food item food frequency questionnaire	Oral cavity, pharynx	Intakes of beef, poultry, fish were not associated with the risk	Control group selection: The controls were hospitalized patients Method of Dietary measure: Food items questioned were limited and hardly allowed any inference concerning total macro- and micro-nutrient intake Dietary confounders: Total caloric intake was not adjusted for data analysis Other confounders: Adjustment made for age and sex, occupation, smoking, drinking
Howe, 1990 (Ref. 73)	Meta-Analysis of 12 Case Control Studies	To evaluate the consistency of 12 studies of diet and breast cancer	varied	breast	Consistent, statistically significantly positive association between breast cancer risk and saturated fat intake in post menopausal women (RR = 1.5 p < .0001)	Not controlled for: Total Caloric intake. Problem of multiple comparisons
Buiatti 1990 (Ref. 74)	case-control study in Italy: 1016 cases 1159 population-based controls	To evaluate dietary factors and their contribution to gastric cancer mortality	Dietary questionnaire: frequency of intake and portion size in 12 month period 2 years before interview (146 food items)	stomach	Decreased cancer risk with increased vegetable fat (statistically significant) No association with animal fat	Didn't adjust for total calories
Baghurst, 1991 (Ref. 75)	Case-control 104 cases, 253 population-based controls	Assess relationship of diet to pancreatic cancer	Quantitative food frequency questionnaire 179 food items (usual intake)	pancreas	Increased risk with increased cholesterol intake (significant); increased risk with decreased PUFAS (significant) Others not significant when controlled for total energy	Controlled for total energy Difficult to interpret results

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Demirer, 1990 (Ref. 76)	Case-control (Turkey) 100 cases 100 control population-based and hospital (39+61)	Assesses role of diet in stomach cancer	Dietary questionnaire assessed for past 15 years	stomach	Increased risk with decreased meat consumption (statistically significant)	Poorly controlled study Fat consumption is not measured directly
de Verdieu, 1990 (Ref. 77)	Case-control (Sweden) 720 cases (268 rectal, 452 colon) 624 controls population based	Assess association between colorectal cancer and intake of total energy, protein, fat, fiber and body mass	Quantitative food frequency questionnaire (55 food items) for previous 5 years	colorectal	The following are significant for trends only, not for individual levels: Increased risk with increased energy Increased risk with increased total fat (for both colon and rectal cancers) Also increased risk with increased saturated fat increased risk with increased monounsaturated fat increased risk with increased PUFAS rectum only	Adjusted for fiber intake only, not total energy. High non response rate among cases (21%)
Farrow and Davis, 1990 (Ref. 78)	Case-control (148 male cases, 188 population-based controls)	Assess relationship between diet and pancreatic cancer	Telephone interview and self administered food frequency questionnaire (135 food items assessed 3 years prior to diagnosis	pancreatic	Increased risk with increased protein only (statistically significant); no risk associated with total fat, saturated fat, cholesterol, or omega-3 fatty acids	Wives used as surrogates when necessary for cases and for controls Controlled for total caloric intake Adjusted for major risk factors of pancreatic cancer such as smoking Study is well done

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Jain, 1990 (Toronto) (Ref. 79)	Case control 839 cases 772 controls (pop-based)	Dietary factors and lung cancer risk	In-person interview diet consisted of 81 food items (usual intake)	lung	Borderline increased risk with highest cholesterol consumption level No association with fats	Dietary questionnaire focused on usual intake, which could be influenced by disease, rather than 2-3 years previously Controlled for smoking but not total energy
Kato, 1990 (Japan) (Ref. 80)	Case-control 427 cases 3014 controls(all underwent gastroscopic examination)	Assess stomach cancer risk factors for purposes of prevention	Dietary questionnaire self administered; limited number of food items-usual intake	stomach	No association with meat consumption or "Western-style breakfast (actual fat intake not measured)	No adjustment for confounding factors (smoking, total energy) Fat consumption not assessed directly Controls underwent gastroscopic exam so potentially could be diseased (i.e., misclassification bias)_
La Vecchia, 1990 (Italy) (Ref. 81)	Case-control (110 women cases and 843 hospital controls for acute conditions non-neoplastic, non-respiratory	Laryngeal cancer risk and dietary factors	In person questionnaire 10 indicator foods assessed prior to onset of symptoms	laryngeal	No relationship with indicators of dietary fat	Controlled for smoking and some other confounders but not total energy Limited dietary assessment
La Vecchia (1990) (Ref. 82)	Case-control 247 cases 1089 controls hospitalized for acute nonneoplastic or digestive conditions	Diet and pancreatic cancer	In-person questionnaire on 14 indicator foods assessed at least 1 year prior to onset of symptoms	pancreas	No relationship with indicators of dietary fat	Controlled for smoking and some other confounders but not total energy Limited dietary assessment

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Maclure, 1990 (Ref. 83)	Case-control 410 cases 605 controls (population based)	Assess dietary factors in risk of renal adeno-carcinoma	Questionnaire in person at home on average food consumption in early 1970's	Renal	Animal fat and saturated fat weakly associated with risk, with and without adjustment for energy Total energy not associated	Recall bias 20-year period for recall Well controlled Low participation rate (69% for cases and 59% for controls)
Mettlin, 1990 (Ref. 84)	Case-control (303 cases and 606 controls hospitalized for non-malignant diseases	Assess ovarian cancer risk in relationship to milk drinking (lactose)	Self-administered questionnaire with 66 food items assessed prior to onset of symptoms	ovarian	Total milk consumption not associated with increased risk Drinking whole milk regularly associated with increased risk compared with drinkers of skim and 2%	Can not use results of this study to assess risk of fat consumption Authors assume that whole milk is a major source of dietary fat among adults (but didn't assess cooking milk, etc)
Stemmermann, 1990 (Ref. 85)	Prospective 8006 Hawaii Japanese men ages 46-68 at the beginning of the study 22 years duration	To assess the impact of fat and calcium intake on the risk of developing cancer in each large-bowel subsite	24 hours diet recall interview	colon/rectal	Age-adjusted mean intake of fat in patients with colon cancer is lower than that of non-cases (P=.05) no difference between rectal cases and non-cases. No interaction between fat and calcium intake No difference in mean calcium intake between colon or rectal cancer cases versus non-cases	Not adjusted for total energy intake

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Slatery, 1990 (Ref. 86)	Case-control white males from Utah aged 45-74; 362 cases, 685 population-based controls	To evaluate prostate cancer risk associated with fat consumed during adolescent years	Food frequency questionnaire-compared reported results with national food consumption trends to assess the accuracy of the dietary instrument	prostate	Men who consumed a high fat dies as adults were at a slightly increased risk of developing aggressive prostate cancer after adjustment for adolescent diet (OR=1.8, P=.05) whereas men who consumed a high saturated fat diet as adolescents were not at increased risk of developing these tumors after controlling for adult diet.	Recall bias large factor Multiple confounders not adjusted for (only age and high saturated fat diet in adolescent) Total energy intake not adjusted Borderline significance
Zhang, 1990 (Ref. 87)	Case-control of Chinese women in Shanghai: 186 cases, 186 hospital controls, 186 neighborhood controls	To assess the relationship between diet and breast cancer	Diet Histories	Breast	Cases have a significantly greater daily caloric intake than controls. After adjusting for the total energy intake, increased consumption of total fat is significantly associated with breast cancer (RR is 1.7, p =.05) for the highest vs lowest quintile of fat intake.	Well-done analysis. Major confounders adjusted for. Both hospital and neighborhood control used.
Slattery, 1988 (Ref. 88)	Case-control - Cases: 119 females, 110 males Controls: 204 females, 180 males	To assess the relationships of physical activity and diet to the development of colon cancer in Utah.	quantitative food-frequency questionnaire	colon	Total fat intake shows borderline increase in the risk for colon cancer in males (OR = 2.1, P=.09) and females (OR = 2.0, P=.09) between highest and lowest range of intake. Adjusted for age, BMI and fiber intake	Total energy intake not adjusted for.

Table 2--continued

Reference (author, date)	Study Design and Population	Objective	Method of Dietary measure	Type of cancer	Results	Assessment
Hislop, 1990 (Ref. 89)	Case-control of Canadian women; Cases: 801 histologically confirmed benign breast disease Controls: 865 age-matched	to investigate the relation between diet and histologic types of benign breast disease	self-administered questionnaire consisting of usual frequency of consumption during the past year of 39 specific food items	breast	Severe atypias and borderline carcinoma in situ were directly associated with frequent meat fats consumption (result not statistically significant: OR = 3.2 ; 95% CI 0.75-13.21)	Small subgroups; findings not statistically significant
Morales Suarez-Varela, 1990 (Ref. 90)	cross-sectional	to evaluate the relation of Spanish diet to rectal cancer morbidity and mortality	consumption by province was determined from National Statistics Institute publications for total lipids, total animal fats, total vegetable fats (in g/person/day)	rectal and colon	a positive correlation between morbidity and mortality and total lipid consumption was found. All morbidity and mortality rate (males, females and total) showed correlation in excess of .4 ($p<.001$)	Total energy not adjusted Lifestyle confounders not adjusted (smoking, etc)

21 CFR Part 101

[Docket No. 91N-0095]

RIN 0905-AB67

Food Labeling: Health Claims and Label Statements; Sodium/ Hypertension

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule.

SUMMARY: The Food and Drug Administration (FDA) is proposing to authorize health claims on food labels and labeling that state that a low sodium diet is associated with lower blood pressure in some people. The agency reviewed the relationship between dietary sodium intake and hypertension under provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). On the basis of this review, the agency tentatively concludes that there is significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims, and that the strength and consistency of the publicly available scientific evidence supports such claims. The agency's tentative conclusion is based on its review of the scientific literature and on review of conclusions and recommendations provided in Federal government and other authoritative documents.

DATES: Written comments by February 25, 1992. The agency is proposing that any final rule that may issue based upon this proposal become effective 6 months following its publication in accordance with requirements of the 1990 amendments.

ADDRESSES: Written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, rm. 1-23, 12420 Parklawn Dr., Rockville MD 20857.

FOR FURTHER INFORMATION CONTACT: Ellen M. Anderson, Center for Food Safety and Applied Nutrition (HFF-266), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-472-5375.

SUPPLEMENTARY INFORMATION:

I. Background

A. The Nutrition Labeling and Education Act of 1990

On November 8, 1990, the President signed into law the 1990 amendments (Pub. L. 101-535), which amended the Federal Food, Drug, and Cosmetic Act (the act). The 1990 amendments, in part, authorize the Secretary of Health and Human Services (the Secretary) to issue regulations authorizing nutrient content and health claims on the label or labeling of foods. With respect to health claims, the new provisions provide that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with the procedures and standards established under section 403(r)(1)(B) of the act (21 U.S.C. 343(r)(1)(B)).

Published elsewhere in this **Federal Register** is a proposed rule to establish general requirements for health claims that characterize the relationship of nutrients, including vitamins and minerals, herbs, or nutritional substances (referred to generally as "substances") to a disease or health related condition on food labels and in labeling. In this companion document, FDA has tentatively determined that such claims would be justified for dietary supplements as well as conventional foods only if the agency determines based on the totality of the publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles) that there is significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The 1990 amendments also require (section 3(b)(1)(A)(ii), (b)(1)(A)(vi), and (b)(1)(A)(x)) that, within 12 months of their enactment, the Secretary shall issue proposed regulations to implement section 403(r) of the act (21 U.S.C. 343(r)), and that such regulations shall determine, among other things, whether claims respecting 10 topic areas, including sodium and hypertension, meet the requirements of section 403(r)(3) of the act (21 U.S.C. 343(r)(3)). In this document, the agency will consider whether a claim on food or food products, including conventional foods and dietary supplements, on the relationship between sodium and hypertension would be justified under the standard proposed in the companion document entitled "Food Labeling: General Requirements for Health Claims for Food: Proposed Rule."

B. Sodium/Hypertension Relationship

1. Hypertension

Hypertension, commonly referred to as high blood pressure, is a serious public health concern. One in three adults in the United States is hypertensive (Ref. 85) approximately 58 million adults (Ref. 23). Individuals with high blood pressure have an increased risk of developing stroke, heart disease, and several types of kidney disease (Refs. 43 and 62). Heart disease and stroke are 2 of the 10 leading causes of death in the United States (Ref. 43). In 1988, 35.3 percent of all deaths were attributable to heart disease and 7.9 percent to stroke (Ref. 82).

In spite of improvements in the awareness and control of hypertension and a decline in related mortality rates for heart disease and stroke, hypertension continues to be a serious public health problem. Developing strategies to lower blood pressure in the general population remains an important public health goal (Ref. 74).

2. Sodium and Salt

Sodium is an essential nutrient with a variety of physiological functions (Ref. 63). It is the major electrolyte of blood plasma and other noncellular fluid and is essential for maintenance of fluid and electrolyte balance within the body. Sodium is also necessary for normal kidney function, nerve conduction, and muscle contraction (Ref. 7).

Sodium requirements vary with age, physical activity, environmental factors, and pregnancy status. Estimates have been made for safe minimum daily requirements for sodium in healthy persons taking into account wide variations in climate and physical activity but not including an allowance for large or prolonged sweat losses. These estimates range from approximately 300 milligrams (mg) per day for children 2 through 5 years of age to 500 mg per day for adults over 18 years of age (Ref. 63). In the United States, sodium is generally consumed well in excess of bodily needs. Dietary intake estimates range from 3,000 to 6,000 mg per day (refs. 18, 34, 35, and 43).

3. Relationship Between Sodium and Hypertension

An association of salt intake with high blood pressure was first observed in 1904 (Ref. 1). Since then, considerable experimental evidence linking sodium intake to hypertension has accumulated (Ref. 14). This increasing body of evidence resulted in public health concerns about the high levels of sodium intake in the U.S. population (Refs. 3, 9, 11, 22, 43, 62, 63, and 85). Consequently, a series of recommendations for Americans to moderate or reduce their sodium consumption have been made (Refs. 43, 62, 63, and 85).

Despite widely accepted recommendations to reduce or moderate sodium intake, estimating the

effectiveness of sodium restriction in reducing blood pressure has proven difficult because high blood pressure has many causes, and blood pressure levels are affected by many factors. The 1990 amendments require FDA to review and evaluate the data on sodium and hypertension to determine whether health claims on this topic are appropriate.

C. Sodium: Regulatory History

Sodium and salt have long regulatory histories. Salt (sodium chloride) has been regulated as an ingredient (21 CFR 100.140) and a flavoring (21 CFR 101.22). It has traditionally and historically been regarded as a generally recognized as safe (GRAS) substance (21 CFR 182.1). Sodium has been regulated as an essential nutrient (21 CFR 107.10, 21 CFR 107.100, and current 21 CFR 101.9). However, in the early 1980's, concern over high sodium consumption led to the GRAS safety review of sodium chloride (June 18, 1982, 47 FR 26590) and to FDA regulations (June 18, 1982, 47 FR 26580; April 18, 1984, 49 FR 15510) to include sodium content information on nutrition labels (current 21 CFR 101.9), to define descriptive terms for "low sodium" and "reduced sodium" foods (current 21 CFR 101.13), and to permit sodium labeling without full nutrition labeling on foods used to regulate sodium intake (21 CFR 105.69).

The intent of these regulations was to provide guidelines for sodium and salt labeling on foods, to establish definitions for descriptor terms useful in labeling foods low in sodium and salt, and to encourage manufacturers to provide a greater number and variety of low sodium foods. The emphasis was on developing and maintaining policies appropriate for the general public so that consumers could structure their diets to meet individual health needs, and so that medical professionals could better manage those patients requiring control of dietary sodium intake. Two quotes summarize the agency position in 1982 to 1984. The first refers to the general public:

> Adult intake of sodium in the United States is in excess of physiological needs, and it would be prudent for the general population to reduce sodium intake whenever possible. The role of excess dietary sodium in the development of hypertension needs to be defined more clearly, but there is no evidence that a moderate reduction in sodium intake for the general public would have any adverse effects, and there is a strong indication that such a reduction would be beneficial to a large segment of the population. (47 FR 26580 at 26581.)

The second quote refers to that portion of the U.S. population predisposed to hypertension:

> Although many epidemiological studies indicate a relationship between sodium intake and the prevalence of hypertension, the evidence that sodium consumption is a major factor in causing hypertension is not fully conclusive. Nevertheless, the evidence is strong enough for most members of the medical and scientific community to conclude that a substantial portion of the U.S. population which is predisposed to hypertension would benefit from a reduction in dietary sodium. (47 FR 26580 at 26581.)

In the **Federal Register** of June 18, 1982 (47 FR 26590), FDA reviewed the GRAS status of sodium chloride. Regulatory action was deferred until the agency could assess the impact of sodium descriptor and labeling regulations and voluntary efforts of manufacturers to reduce the salt and sodium content of their products. It was recognized that salt occupies a unique place in the food supply because it occurs naturally in foods, has a wide variety of manufacturing uses, and has a long history of direct consumer use in food preparation and at the table. In addition, the level of dietary sodium recommended for different individuals varies widely, from severe sodium restriction for some hypertensive patients, to moderate restriction for others, to general recommendations to reduce sodium intake for the general public. FDA concluded that it would be impractical to set upper safe limits for salt in individual foods, and that it was more appropriate to provide sodium content information than to try to restrict sodium use. In the years following the sodium labeling initiatives, FDA has taken no further action on the GRAS status of salt.

Consideration of health claims for a sodium and hypertension relationship was first proposed by FDA in a reproposed rule on health messages published on February 13, 1990 (55 FR 5176). Sodium and hypertension was proposed as one of six possible topics most likely to be suitable for health claims.

Elsewhere in this issue of the **Federal Register**, FDA is publishing a supplementary proposal on mandatory nutrition labeling, Reference Daily Intakes (RDI's), and Daily Reference Values (DRV's) for nutrients. The proposed DRV for sodium is 2,400 mg. Also in this issue of the **Federal Register**, FDA is proposing a revision of nutrient content claims that include sodium content claims.

D. Evidence Considered in Reaching the Decision

The agency has reviewed relevant scientific evidence on sodium and hypertension. Federal government documents considered include the Surgeon General's Report on "Nutrition and Health" (Ref. 43), the U.S. Department of Agriculture's (USDA) and the Department of Health and Human Services, (DHHS) "Nutrition and Your Health—Dietary Guidelines for Americans" (Ref. 85), the National Institute of Health (NIH), National Heart, Lung, and Blood Institute's (NHLBI) "The 1988 Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (Ref. 38), and the NIH/NHLBI Hypertension Workshop (Ref. 103).

The agency also reviewed additional documents prepared by recognized scientific bodies: The National Academy of Sciences/National Research Council's (NAS/NRC) "Diet and Health—Implications for Reducing Chronic Disease Risk" (Ref. 62), and the NAS/NRC "Recommended Dietary Allowances" (Ref. 63). FDA recently contracted with the Federation of American Societies for Experimental Biology (FASEB), Life Sciences Research Office (LSRO) to prepare an independent evaluation of the available scientific evidence on the relationship between sodium and hypertension. The agency has also considered the results of this "Sodium and Hypertension" review (Ref. 108). These reports considered the weight of the publicly available scientific evidence up until their publication, and they provided a foundation for studies published subsequently. The agency considered the results of animal studies to the extent that they clarified human studies or suggested possible mechanisms of action. FDA updated the evidence in these documents by reviewing relevant human studies that have become available since 1988. The agency evaluated one major, multinational investigation (Ref. 37), four clinical trials (Refs. 44, 70, 79, and 109), and three meta-analyses (Refs. 100, 106, and 107).

To ensure that its review of relevant evidence was complete, FDA requested, in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas identified in section 3(b)(1)(A) of the 1990 amendments. The topic of sodium and hypertension was among the 10 subjects on which the agency requested information.

E. Comments Received in Response to FDA Request for Scientific Data and Information

FDA received 13 comments in response to the **Federal Register** request for data and information about the relationship between sodium and hypertension (56 FR 12932). One comment was a request for an extension for additional time for comments, and this request was denied because of the limited time available. Several provided comments about the general process of writing health claims. Others expressed opinions in support of or in opposition to sodium reduction or health claims for sodium and hypertension. Among those taking positions, a manufacturer and a trade association opposed reducing sodium intake and sodium/hypertension health claims. Reduced sodium intake and sodium/hypertension health claims were supported by a professional health association, a distributor of health foods, and a foreign government.

Comments from a trade association stated that health claims were inconsistent with the statutory requirements of the act. However, this comment was contained in a letter that was written before the enactment of the 1990 amendments which explicitly authorize health claims.

Comments from a State department of health, an association of State and territorial public health nutrition directors, a trade association, and a distributor of health foods included support for the 1990 amendments and the Surgeon General's report (Ref. 43). The comments favored requiring significant scientific agreement as a precondition to a health claim and suggested that FDA should authorize such claims only if other nutrient levels do not contradict the health benefits from the substance. These comments said that such claims should emphasize the total diet rather than individual foods, supplementation, or fortification. Some expressed concern that industry could abuse health claims or that the general public could misinterpret them. One suggested that FDA should do a literature search to obtain an impartial selection of data for review. Another emphasized that the public should continue to rely on modern medicine for the cure and mitigation of diseases. FDA believes that the proposed rule is responsive to these concerns.

Comments from a health food distributor and a professional health association made recommendations about levels of daily sodium intake. The health food distributor advised that adult sodium intake should not exceed 1,600 mg per day, while the professional health association recommended that adult sodium intake should not exceed 3 grams (g) (3,000 mg) per day. In this issue of the **Federal Register**, as stated above, FDA is proposing a DRV of 2,400 mg of sodium per day. Comments concerning recommended daily sodium intakes are more appropriately discussed in response to the establishment of a DRV for sodium. Copies of these two comments have been placed under Docket No. 90N-0134.

A distributor of health foods recommended a two-tiered approach to establishing the maximum amount of sodium that a food could contain and still bear a health claim. It suggested an absolute value (less than 100 mg of sodium per 100 calories) and recommended a secondary criteria based on the naturally occurring sodium levels in the various food categories. The health food distributor emphasized the importance of maintaining standard levels of other important nutrients and suggested that sodium/hypertension health claims would be misleading on low sodium foods if other ingredients in the food caused increased hypertension. These issues have been addressed in the proposed regulation on general requirements for health claims published elsewhere in this issue of the **Federal Register**.

Comments from a trade association suggested that health claims should be national in scope and uniform nationwide, and that FDA should not proceed without the resources to adequately enforce any new regulations. Under the 1990 amendments, regulations established by FDA on health claims are national in scope. FDA is required to prepare appropriate regulations in response to the congressional mandate. The agency will enforce the food labeling regulations to the best of its ability with the resources available.

Comments from a trade association suggested that model label statements should be created by expert advisory committees, evaluated through consumer testing, and published in the **Federal Register** for public comment. Manufacturers will have the latitude to develop claims that meet the requirements of the rule. FDA has tentatively decided that, under the act, the appropriate course is for the agency to determine the requirements that a health claim must meet. In this and other documents, FDA is proposing to authorize health claims and is proposing a model claim. FDA is inviting public comment on that model claim as well as on the proposed rule.

Comments from both a State health department and a health food distributor suggested that health claims should recognize the populations affected, refer to other factors that contribute to the disease, and emphasize the overall diet and lifestyle and not overstate the effectiveness of the nutrient or allow short descriptive statements separate from the total health claim. As discussed below and in the document on general principles for health claims, FDA's proposal is responsive to these concerns.

Several organizations sent in references for scientific studies. All recent and pertinent studies and comments concerning the scientific evaluation are included in the scientific review and summary elsewhere in this document.

A comment from a trade association included detailed objections to the Surgeon General's report (Ref. 43) and the NAS report (Ref. 62) and suggested that the documents were outdated, incorrect, incomplete, and biased. The comment concluded that the reports should not be given special consideration. FDA disagrees with these comments and believes that the documents are appropriate for consideration.

The Canadian Government also submitted a comment, outlining its position on the relationship of diet and nutrients to disease. The position reflects the work of the Canadian Scientific Review Committee (the Committee) (Ref. 84). The Committee reviewed the scientific data and recommended that the sodium content of the Canadian diet should be reduced. The report stated that there were insufficient data to support a quantitative recommendation. However, it concluded that a reduction in current sodium intakes of the Canadian population would involve no risk. Canada also pointed out that its Food and Drug Act expressly prohibits the sale or advertisement of foods represented to treat, prevent, or cure hypertension and other diseases.

II. Review of the Scientific Evidence

A. Introduction

Definitions of hypertension are related to both contracting, or systolic, blood pressure (SBP) and resting, or diastolic, blood pressure (DBP) measurements, are based on correlations with risk of heart disease and stroke, and differ by organization and purpose (Refs. 4, 17, 27, and 38). Currently, individuals with SBP greater than or equal to 140 millimeters of mercury (mm Hg) or DBP greater than or equal to 90 mm Hg or currently taking

antihypertensive medication are considered hypertensive. Those with SBP less than 140 mm Hg and DBP less than 90 mm Hg are considered normotensive (Refs. 17, 38, and 83). "High normal" DBP is defined as DBP between 85 and 89 mm Hg. All definitions are currently under review by the NIH/NHLBI Joint National Committee.

In considering the scientific evidence on the relationship between dietary sodium intake and hypertension, FDA reviewed three Federal government documents (Refs. 38, 43, and 85), a Federal government workshop (Ref. 103), and three other documents from recognized scientific bodies (Refs. 62, 63, and 108). FDA also reviewed the human studies that have become available since these documents were written. The agency included in its review English language reports of primary human studies involving sodium and hypertension specifically. FDA considered review articles and issues involving hypertension or other nutrients only as they related to the primary relationship between sodium and hypertension.

B. Federal Government Documents

1. "The 1988 Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure"

"The 1988 Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (Ref. 32) noted that research on hypertension prevention was in progress, and that recommendations for ways to prevent hypertension could not yet be made. It concluded that population studies suggest that low sodium intake, weight reduction, and moderation of alcohol consumption may contribute to prevention of age-related increases of blood pressure. The report noted that "high sodium intake plays a critical role in maintaining the elevated blood pressure of some hypertensive patients and in limiting the effectiveness of certain antihypertensive drugs," and that "some patients with mild or moderate blood pressure elevation may achieve control through moderate sodium restriction." The report observed that there is no easy way to identify specific individuals who would profit from sodium restriction and indicated that moderate sodium intake (approximately 1,500 to 2,500 mg per day) produced no serious adverse consequences.

2. "The Surgeon General's Report on Nutrition and Health," 1988

"The Surgeon General's Report on Nutrition and Health" (Ref. 43) observed that epidemiological studies have shown that, in populations with low sodium intake, blood pressure does not rise with age, and that populations with low blood pressure do not generally consume much salt. The report noted that the correlation between salt intake and blood pressure is not consistent in population studies, and that the associations among individuals within a population have been less consistent, which may be due to methodological reasons.

The report observed that long-term clinical studies have shown that 40 percent of hypertensive patients and 30 percent of mildly hypertensive patients could control their blood pressures by reducing sodium intake below 1,150 and 1,720 mg per day, respectively. It further noted that the effect of sodium restriction has been less well studied in normotensive populations as compared to hypertensive populations. There are fewer studies of normotensive individuals, and the studies have been small in size and short in duration. A few studies have indicated that dietary sodium restriction in normotensive adults or infants can result in small blood pressure decreases.

The report observed that intervention studies have suggested that sodium restriction and weight control can be beneficial in helping control hypertension in mildly hypertensive individuals who have discontinued their antihypertension medication.

The Surgeon General's Report on Nutrition and Health" concluded that "[d]ietary factors that clearly contribute to high blood pressure include obesity and excessive intake of sodium and alcohol," and that "[s]tudies indicate a relationship between a high sodium intake and the occurrence of high blood pressure and stroke."

The report observed that the average sodium consumption by U.S. adults (4,000 to 6,000 mg per day) significantly exceeds the range that NRC estimated in 1980 as would be a safe and adequate daily intake (1,100 to 3,300 mg). It noted that there is no easy way to identify individuals who would profit from sodium restriction, and that some individuals appear to respond to sodium restriction and are considered "salt-sensitive" and others do not respond and are considered "salt-resistant." The report observed that there is no practical way of distinguishing the two groups other than by measuring the blood pressure response itself. It concluded that moderate reduction of dietary sodium would not be harmful and might be of significant benefit to that portion of the population at risk of developing hypertension. The report suggested that most Americans should consider reducing their sodium intake by choosing foods with less sodium, using less sodium in food preparation, and adding less sodium at the table.

3. "Nutrition and Your Health—Dietary Guidelines for Americans," 1990

In 1990, "Nutrition and Your Health—Dietary Guidelines for Americans" (Ref. 85) made seven nutrition recommendations for the U.S. population. Among other suggestions, it stated that Americans should "[u]se salt and sodium in moderation" and recommended that Americans choose foods with less sodium, use less sodium in food preparation, and add less sodium at the table.

4. Summary

These three Federal government documents acknowledged a relationship between sodium intake in excess of physiological need and the prevalence of hypertension. There was agreement that limiting dietary sodium may benefit a portion of the population with elevated blood pressures, i.e., be of benefit for some hypertensive individuals. Dietary Guidelines and the Surgeon General's report also indicated that in addition to benefitting individuals identified as hypertensive, moderation of dietary sodium might also benefit the portion of the normotensive population at risk of developing hypertension.

C. Federal Government "Workshop on Salt and Blood Pressure," 1989

On November 1 and 2, 1989, NHLBI sponsored a "Workshop on Salt and Blood Pressure" to review the scientific evidence on the relationship between sodium and blood pressure, to consider the variability in human response, to review research findings relative to clinical and public health policies, and to provide recommendations for future research (Ref. 103). Three articles that resulted from this workshop (Refs. 109, 111, and 114) are discussed elsewhere in this document. Positions and opinions expressed at the meeting were highly polarized on the value of salt restriction. A wide range of topics was presented, and the scientific discussions reflected the controversy surrounding this topic. Some participants at the conference supported reducing sodium intake and argued that the relationship is scientifically supported (Refs. 94, 97, and

113), that many hypertensives are "salt-sensitive" (Ref. 95), that there are no negative consequences of decreased sodium intake (Ref. 98), and that since the target population cannot be identified easily or cheaply (Ref. 104), a population approach, which is often used for nutrition policies (Ref. 99), is necessary (Ref. 104). Some indicated that reductions in sodium intake are possible because interventions have been successful and have made significant contributions to treatment and prevention (Ref. 98). Others contended that only expensive, labor-intensive interventions with highly motivated participants have been successful (Ref. 105), and that the most pragmatic approach would be to alter the sodium content of the entire food supply (Refs. 102 and 105).

Other participants opposed reducing sodium intake and contended that more research is necessary because electrolytes other than sodium may affect hypertension (Ref. 110). Some indicated that sodium restriction affects people in very different ways, and that some individuals might be closer to a critical deficit of extracellular fluid or might have more difficulty reconstituting losses after acute salt-depleting stress. They argued that sodium reduction should be used only for individuals at risk and for those in whom it has proven effective (Ref. 112). Some asserted that long-term, substantial reductions in sodium intake have not been successfully achieved in comparative trials (Ref. 113).

D. Other Documents and Statements

1. "Diet and Health—Implications for Reducing Chronic Disease Risk," 1989

The NAS "Diet and Health—Implications for Reducing Chronic Disease Risk" (Ref. 62) observed that cross-cultural, epidemiological studies show that blood pressure does not increase with age, and that there is a low prevalence of hypertension in populations with low sodium intake. However, the relationship between low sodium intake and low blood pressure or low incidence of hypertension has been less consistent in epidemiological studies within individual cultures. The report noted that INTERSALT, a large, multinational, pooled study, showed both a small but significant positive correlation between sodium excretion and mean SBP and also a significant positive correlation between sodium excretion and increases in blood pressure that occur with age (Ref. 37).

The report observed that small, short-term clinical studies suggest that sodium restriction is related to reductions in blood pressure in normotensive individuals. However, these results have not been confirmed in long-term, prospective, controlled trials in normotensive populations.

The report noted that animal studies support the conclusions from human studies. High salt intake appears to promote the development of high blood pressure in some animal models, especially when renal defects reduce the ability of the kidney to excrete salt. The report noted that these findings suggest that high-salt diets in combination with reduced sodium excretion may be related to the development of hypertension in humans. It further noted that, once high blood pressure is induced by high sodium intake, it cannot necessarily be reversed by resumption of a moderately low intake, due probably to irreversible changes in the kidney.

"Diet and Health—Implications for Reducing Chronic Disease Risk" concluded that: "[b]lood pressure levels are strongly and positively correlated with the habitual intake of salt," and that "the weight of evidence supports the contention that intake of sodium is an important factor in the occurrence of hypertension." The report recommended that total daily salt intake should be not greater than 6 g (2,400 mg sodium), with a possible future goal of 4.5 g salt (1,800 mg sodium). It suggested reducing salt and sodium intake by choosing low sodium foods and using less sodium in food preparation and at the table. The report observed that there is a wide variability in genetic susceptibility to salt-induced hypertension, that some people are more salt-responsive ("salt-sensitive") than others, and that there is no reliable way to identify individuals in the population who would benefit from sodium restriction. It concluded that limiting dietary sodium may be of significant benefit to that portion of the population at risk of developing hypertension and noted that the recommended intake levels would not be harmful to the general public.

2. "Recommended Dietary Allowances," 1989

"Recommended Dietary Allowances," 10th Edition (Ref. 63) noted that: "[s]ustained overconsumption of sodium, particularly as salt, has been related to development of hypertension in sensitive individuals." It supported the recommendation of the NAS Report to limit daily sodium intake to 2,400 mg. It noted that 500 mg sodium per day is a safe minimum intake for adults, and that there is no known advantage in consuming large amounts of sodium.

3. "Dietary Sodium Chloride and Blood Pressure," 1991

FASEB recently prepared an independent evaluation of the available scientific evidence on the relationship between sodium and hypertension (Ref. 108). The FASEB report concluded that the association between increased sodium or salt intake and increased blood pressure is due to sodium and chloride in combination, and that the increase is mitigated by the presence of potassium and calcium ions. It indicated that the most convincing evidence comes both from studies across populations and from controlled clinical trials which have shown a small, significant positive correlation between dietary sodium chloride intake and blood pressure for hypertensive and normotensive individuals.

The FASEB report noted that studies within populations have been inconclusive or have shown a low correlation. The report noted that there was little long term information about the effect of dietary sodium intake on the development of hypertension, and that the available data have been inconclusive. The report concluded that observational data and intervention trials document a small, but consistent effect of dietary sodium chloride on blood pressure.

4. Summary

There is general agreement among the three authoritative documents that there is a relationship between sodium intake and hypertension.

E. Review of the Scientific Evidence Since the Authoritative Reports

1. INTERSALT, 1988

INTERSALT (Ref. 37) was a large, multinational investigation of the relationship between electrolytes, including sodium, and blood pressure (Table 1). The intent was to apply highly standardized methods across varied populations, to examine the major confounding factors, and to evaluate the relationships in individuals (Ref. 64). The study involved 10,079 adults in 52 population centers around the world (Refs. 37, 50 through 54, 58, 59, and 64). Within-individual variability in sodium excretion was estimated using data from a random sampling (8 percent) of individuals who provided two 24-hour urine collections. The within-center data were pooled, and a statistically significant relationship between sodium intake and increased SBP was reported. A relationship between sodium intake and DBP was significant under some analysis conditions and not others.

Similar results were found when the data were analyzed by gender and by age (Ref. 51), and when the normotensive population was considered independently (Ref. 50).

The across-center data analysis considered relationships between sodium intake and blood pressure and between sodium intake and trends in blood pressure with age. The data were analyzed with and without four isolated population centers, two Brazilian Indian (Yanomamo and Xingu), the Papua New Guinean, and the Kenyan. These four centers had exceptionally low median sodium intakes (ranging from 5 to 1,180 mg per 24 hours) and the lowest average blood pressures of all 52 centers (SBP of 103 mm Hg, DBP of 63 mm Hg) (Ref. 58). The relationship between sodium intake and blood pressure, across centers, was strongly dependent on the inclusion or exclusion of these four populations. When these populations were included, the relationship between sodium intake and blood pressure was positive and significant. Results were negative and significant or inconclusive when these four populations were excluded from the analysis. The relationship between sodium intake and trends in blood pressure with age was positive and significant under all analysis conditions. The four centers with exceptionally low sodium intakes had little or no upward slope of blood pressure with age and low prevalence of hypertension (5 percent in Kenya, absent in remaining three centers) (Ref. 58). The Yanomanu Indians consumed as little as 1 mg of sodium in 24 hours and appeared healthy and physically active with no evidence of malnutrition or protein deficiency (Ref. 59).

The INTERSALT Cooperative Research Group analysis included adjustments for age, sex, potassium excretion, body mass index, and alcohol intake. The group estimated that an average sodium reduction of 100 millimole (mmol) per day (2,300 mg sodium) would correspond to an average reduction in SBP and DBP of 2.2 mm Hg and 0.1 mm Hg, respectively, on a population basis. In addition, assuming a cumulative effect over time, the group estimated the difference that this 2,300 mg reduction in sodium would have on the age-related increase in blood pressure that is characteristic of Western populations. It calculated that the average blood pressure would increase more slowly and, after 30 years (from 25 to 55 years of age), would be 9.0 mm Hg (SBP) and 4.5 mm Hg (DBP) lower than it would have been with a diet higher in sodium. The INTERSALT Cooperative Research Group concluded that even these small changes in blood pressure could result in important public health benefits when applied to the population as a whole.

In recent years, there have been many published opinions on the INTERSALT findings. In reviewing the totality of publicly available scientific evidence, FDA also included these articles and considered the INTERSALT findings in this total context. The arguments were similar to those expressed at the government workshop discussed above. Several authors supported sodium restriction and emphasized the predicted benefits on a population basis (Refs. 52, 60, 69, 75, 111, and 114). Two authors objected to sodium restriction, contended that it is unclear whether the relationship is nonexistent or small with negligible benefit, and expressed concern about potential adverse effects of sodium restriction (Refs. 90 and 120).

The Stamlers, et al. (Refs. 69 and 114) used the INTERSALT data (Ref. 37) to estimate that the 2.2 mm Hg reduction in SBP would correspond to a 4 percent reduction in coronary mortality and a 6 percent reduction in stroke mortality, or 12,000 fewer U.S. deaths each year for people in the age range from 45 to 64. They estimated that the 9 mm Hg reduction in the expected increase in blood pressure from age 25 to 55 would correspond to a 16 percent reduction in deaths from coronary heart disease (CHD) and a 23 percent reduction in deaths from stroke. R. Stamler estimated that 85 percent of the American population have some risk for mortality associated with blood pressure levels (Ref. 114).

2. Clinical Trials (Table 2)

Many of the studies considered involved hypertensive subjects. Dustan and Kirk (Ref. 121) investigated sodium depletion (210 mg sodium per day) and loading (varied by body weight, added 90 mg sodium per kilogram (kg) per day) in 31 hypertensive and 84 normotensive subjects. The authors reported that in hypertensives and some normotensives, mean arterial blood pressure fell with sodium depletion and rose with sodium loading. In other normotensives, blood pressure remained stable throughout. The study phase was very short (4 days sodium depletion, and 3 days sodium loading), and the sodium loading was administered intravenously which introduced additional uncontrolled variability. In addition, the sodium depletion regime was very extreme, allowing only 210 mg sodium per day.

Lasaridis et al. (Ref. 55) studied the responses of 18 (10 male, 8 female) hypertensive patients to controlled diets low (1,150 mg per day) and high (4,600 mg per day) in sodium. Average supine blood pressure rose significantly (6.7 mm Hg). Average standing blood pressure rose (5.0 mm Hg), but the increase was not significant. The study size (18 subjects) was small.

The Australian National Health and Medical Research Council Dietary Salt Study Management Committee (Ref. 44) conducted an 8-week, double blind, placebo-controlled intervention study with 103 (86 male, 17 female) mildly hypertensive subjects (DBP: 90 to 100 mm Hg). Lower and statistically significant decreases in SBP (average decrease of 6.1 versus 0.6 mm Hg) and DBP (average decrease of 3.7 versus 0.9 mm Hg) were observed in the low sodium intake group (1,840 mg sodium per day) as compared to the normal sodium intake group (3,680 mg sodium per day). A large range of variation in individual response was observed but not confirmed.

The Australian National Health and Medical Research Council Dietary Salt Study Management Committee (Ref. 45) continued the intervention study into a crossover design. Eighty eight (73 male, 15 female) subjects continued into the second phase of the study. Similar decreases in SBP (average decrease of 6.0 versus 0.1 mm Hg) and DBP (average decrease of 4.1 versus 0.4) were observed for the low and high sodium intake groups when the data were analyzed as a parallel design identical to that of the first study (Ref. 44). When individual response was considered in accordance with the crossover design of this second study, the average reduction was 3.6 mm Hg (SBP) and 2.1 mm Hg (DBP) in the placebo phase (1,840 mg dietary sodium per day) versus the diet phase (1,840 mg dietary sodium plus 1,840 mg sodium chloride tablets per day).

Koopman et al. (Ref. 76) conducted an intervention trial in 28 mild to moderate hypertensives (average initial SBP of 144.5 mm Hg and DBP of 95.4 mm Hg) to encourage reduced sodium diets through dietary counseling and feedback from results from urinary sodium excretion. At the end of 18 months, the average sodium had decreased by 510 mg per 24 hours (from 3,590 to 3,080 mg), accompanying average decreases in SBP of 3.7 mm Hg and in DBP of 4.0 mm Hg. In general, over the 18 months, the sodium intake and blood pressure decreased over the first 6 months and then remained at the lower levels for the rest of the trial period. Four subjects dropped out because of high blood pressure. This was a small study (18 subjects) with no untreated control group (CG).

In another study of mildly hypertensive subjects, Luft et al. (Ref. 79) used a placebo controlled, crossover study design to investigate sodium effects on blood pressure of 10 mildly hypertensive (SBP > 140 mm Hg or DBP > 90 mm Hg) and 10 normotensive (SBP < 140 mm Hg and DBP < 90 mm Hg) subjects (10 male, 10 female) (10 black, 10 white). Sodium chloride (1,810 mg sodium per day) or sodium bicarbonate (1,810 mg sodium per day) supplements were supplied with a controlled basal diet (1,380 mg sodium per day). During the sodium chloride intake period, no statistically significant change in blood pressure was observed in either the mildly hypertensive or the normotensive group. The SBP of the mildly hypertensive group was decreased by 5 mm Hg during the sodium bicarbonate intake period. The population size was small (2 groups of 10 subjects).

In another study involving 20 (11 male, 9 female) (5 black, 15 white) mild hypertensives (DBP: 90 to 110 mm Hg), MacGregor et al. (Ref. 122) investigated blood pressure response in a crossover study involving three levels of sodium intake determined by urinary excretion (1,130 mg, 2,480 mg, and 4,370 mg sodium per 24 hours). Blood pressure increased stepwise with sodium intake (SBP: 147, 155, and 163 mm Hg, DBP: 91, 95, and 100 mm Hg). The differences were statistically significant and were not affected by the order of sodium intake.

Several studies involved normotensive subjects. In addition to the two studies considered above (Refs. 79 and 121), Mascioli et al. (Ref. 109) conducted a double blind, placebo controlled, crossover study involving 48 (79 percent male) (1 black, 47 white) normotensive (SBP < 150 mm Hg; DBP: 80 to 89 mm Hg; not on antihypertensive medication or diagnosed as hypertensive) subjects, randomized into two groups, ingesting sodium capsules (2,210 mg sodium per day) or a placebo in addition to a low sodium diet (monitored as less than 805 mg sodium per 8-hour overnight urine collection). In 65 percent of the participants, SBP was higher during the sodium chloride intake period than during the placebo period (Group 1: 4.3 mm Hg higher, 126.4 versus 122.1 mm Hg; Group 2: 2.8 mm Hg higher, 121.4 versus 118.5 mm Hg). In 69 percent of the participants, DBP was higher during the sodium chloride intake period than during the placebo period (Group 1: 2.7 mm Hg higher, 78.8 versus 76.1 mm Hg; Group 2: 1.8 mm Hg higher, 78.5 versus 76.6 mm Hg). The study used timed, overnight, 8-hour urine excretion to assess adherence to low sodium diet.

Mtabaji et al. (Ref. 80) investigated blood pressure response to salt intake in 30 normotensive, black male Tanzanians. In the group on the low sodium diet (1,200 mg per 24 hours), the average mean arterial blood pressure decreased from 87 to 81 mm Hg, whereas, in the group on the high sodium diet (7,750 mg per 24 hours), the average mean arterial blood pressure increased from 86 to 89 mm Hg. The high sodium diet phase was excessively high in sodium (7,750 mg per day).

Three studies, from Scotland (Ref. 41), Japan (Ref. 71), and Belgium (Ref. 42), were cross sectional. The Scottish heart health study (Ref. 41) investigated the relationship of blood pressure to sodium in 7,354 (3,754 male, 3,600 female) free-living subjects from 22 districts in Scotland. The study concluded that there was a weak, positive correlation between sodium and SBP (males: 0.025, females: 0.055) and between sodium and DBP (males: 0.026, females: 0.052) in both sexes. Sodium intake was not independently significant after multivariant analysis. Single sodium measurements in cross sectional studies do not assess previous or habitual sodium intake habits.

Takemori et al. (Ref. 71) considered sodium intake and blood pressure response in 7,441 Japanese females from 88 urban (3933 subjects) and 81 rural (3,508 subjects) municipalities including all prefectures in Japan. The authors concluded that an increase of 2,300 mg sodium per day was related to an increase in SBP of 4.5 mm Hg (urban: 4.1 mm Hg; rural: 4.9 mm Hg) and to an increase in DBP of 1.6 mm Hg (urban: 1.2 mm Hg; rural: 2.0 mm Hg). Spot urine and predictive equations were used to estimate 24-hour sodium which added uncertainty to the results.

Staessen et al. (Ref. 42) conducted a 5-year, cross sectional, intervention trial in two Belgian towns (12,000 and 9,000 inhabitants). A mass media campaign to avoid salt was implemented in one of the two towns, and the second town received no information and served as a control. Data from a random sampling of 777 males and 733 females were analyzed. There were decreases in average urinary sodium, SBP, and DBP for men in the intervention town, and the trends in the control town were not significantly different. In women, sodium decreased in the intervention town and increased in the control town; whereas SBP and DBP decreased similarly in both towns. No conclusions about the relationship between sodium intake and blood pressure could be made. There was a large range of variability in the results, and no independent assessment was made of what information was available to inhabitants in the control town.

Three of the studies were intervention trials. Stamler et al. (Ref. 70) conducted a 5-year, dietary, multiple intervention trial involving 201 subjects with high normal blood pressure (DBP: 80 to 89 mm Hg). The intervention group (IG) was encouraged to reduce alcohol and sodium intakes (goal: 1,800 mg sodium per day or less), reduce weight, and increase physical activity. The intervention group significantly modified their behavior in three of these four categories relative to the control group (CG), increased frequent, moderate physical activity, weight reduction, and sodium reduction (IG: drop of 25 percent from 3980 to 3040 mg sodium per day; CG: drop of 6 percent from 4,300 to 4,060 mg sodium per day). Both groups showed similar reductions in alcohol consumption. After 5 years, the incidence of hypertension (IG: 9 percent; CG: 19 percent), the average SBP (IG: decrease of 2.6 mm Hg from 122.5 to 119.8 mm Hg; CG: decrease of 1.3 mm Hg from 122.7 to 121.5 mm Hg), and the average DBP (IG: decrease of 1.3 mm Hg from 82.5 to 81.2 mm Hg; CG: decrease of 0.1 mm Hg from 82.6 to 82.5 mm Hg) were significantly lower in the IG as compared to the CG. After multiple regression analysis, the independent effect of reduced sodium intake on lowering blood pressure was not statistically significant. Appropriate statistical tools were used to assess the effect; however, the analysis was complicated due to the four simultaneous interventions.

The Hypertension Prevention Trial Research Group (Ref. 124) conducted a dietary counseling intervention involving 841 subjects randomized into four intervention groups and a control. The four interventions involved dietary counseling to encourage reduced calories, reduced sodium, reduced sodium and calories in combination, and reduced sodium and increased potassium. Sodium and blood pressure were reduced in all groups, including the control group. In the sodium only intervention group, sodium was reduced significantly at 6 months and marginally at 3 years. Blood pressure was generally lower in the sodium only intervention group than in the control group, but the decreases were not statistically significant.

The Trials of Hypertension Prevention (TOHP) Collaborative Research Group (Ref. 123) investigated seven nonpharmacological interventions (weight loss and exercise; sodium restriction; stress management; and

supplementation with four nutrients: calcium, magnesium, potassium, and fish oil) relative to a control population, in 2,182 subjects with high normal blood pressure (DBP: 80 to 89 mm Hg). After 18 months, there was a 39 percent reduction in sodium in the sodium restriction population, and SBP and DBP were reduced by 1.5 and 0.8 mm Hg, respectively. The authors concluded that weight loss and sodium restriction were the most promising nonpharmacological interventions.

3. Meta-Analyses

FDA evaluated five meta-analyses (Refs. 94, 97, 100, 106, and 107) which analyzed the effect of sodium intake on blood pressure (table 3). Meta-analyses combine data collected using a wide variety of methodologies, and this complicates data analysis and assessment.

Cutler et al. (Ref. 94) considered 23 randomized clinical trials involving 1536 subjects. Net reductions in sodium ranged from 370 to 3,910 mg sodium, and average pooled reductions in blood pressure were 2.9 mm Hg (SBP) and 1.6 mm Hg (DBP). When hypertensive and normotensive subjects were considered separately, the reductions were larger for the hypertensive subjects (SBP: 4.9 mm Hg; DBP: 2.6 mm Hg) and smaller for the normotensive subjects (SBP: 1.7 mm Hg; DBB: 1.0 mm Hg). The results were statistically significant except for DBP results in normotensive subjects after including adjustments for inverse variance weights.

Elliott et al. investigated the combined results of 14 observational studies involving 12,503 (7,099 male, 6,136 female) subjects in 16 populations. The authors concluded that an average reduction of 2,300 mg sodium per day was related to average reductions in SBP and DBP of 3.7 and 2.0 mm Hg, respectively. Regression coefficients were somewhat larger in women than in men.

Three meta-analyses from one group (Refs. 100, 106, and 107) considered the relationship of sodium intake to blood pressure among populations, within populations, and from clinical trials of salt reduction. In the analysis among populations (47,000 subjects) (Ref. 106), 12 economically undeveloped and 12 economically developed communities were considered separately. The authors developed a model to analyze the relationship of blood pressure to sodium intake. The variability in blood pressure increases with age was controlled by age-stratified analysis. On a population basis, the analysis showed small but consistent increases in blood pressure with increases in sodium intake for both economically developed and undeveloped populations. The magnitude of the increase was greater for older people and for those with higher initial blood pressures. A difference of sodium intake of 100 mmol per day (2,300 mg) was associated with an average change in SBP of 5 mm Hg (ranging from 3 to 7 mm Hg) for those 15 to 19 years of age and of 10 mm Hg (ranging from 6 to 15 mm Hg) for those 60 to 69 years of age. The magnitude of the change was greatest for those with higher initial blood pressure. Smaller changes were observed for those with lower initial blood pressure, but some change was observed in even the lowest blood pressure range.

The within-population analysis of 14 studies (Ref. 100) tested the model developed in the first paper. Using a concept previously applied to 24-hour dietary recall data (Ref. 5), the analysis demonstrated that there is considerable day-to-day variability in sodium intake, determined that a single 24–hour excretion study underestimates the true variance, and used two studies of daily variation to estimate the magnitude of the bias. After adjustment for bias, the magnitude of the correlation between blood pressure and sodium excretion for the within population data agreed with the estimates of the correlation for the among population data in the first paper.

The authors noted that for a small effect, such as the change in blood pressure with sodium intake, very large sample sizes are required to produce statistically significant results because of the substantial random error in measuring sodium intake and the wide range of blood pressures associated with each level of sodium intake. The authors estimated that a study would need to include 400 hypertensive subjects and 400 normotensive subjects to have a 50 percent probability of detecting such a small effect. Doubling the sample size would increase the probability to 80 percent. The authors concluded that, when estimates of the correlation of sodium intake and blood pressure are based on 24-hour dietary intake data, the estimates of the true correlation are too low, and the relationship is stronger than previously reported.

The third analysis included data from 68 crossover trials and 10 randomized controlled trials (Ref. 107). The authors concluded that lower sodium intake was associated with reduced blood pressure in those with high and normal initial blood pressure levels. The authors estimated that, in people between 50 and 59 years of age, a 50 mmol per day (1,150 mg) reduction in sodium intake would lower SBP by an average of 5 mm Hg in the total population and by 7 mm Hg in those with initially high blood pressures. They also estimated that these lower blood pressure levels for the entire population would result in a 26 percent reduction in stroke and a 15 percent reduction in heart disease in Western populations.

Sodium intake was associated with blood pressure. Studies of 4 weeks or less showed smaller differences than studies that lasted 5 weeks or longer.

Taken together, the three meta-analyses concluded that the correlation between sodium intake and blood pressure is stronger than previously estimated, and that the INTERSALT study, among others, underestimated the magnitude of the correlation. The meta-analyses supported the conclusion that modest sodium intake is related to lower blood pressure on a population basis and suggested a beneficial effect on an individual basis, the magnitude depending on the age and the existing blood pressure of the individual.

4. Summary

FDA reviewed the totality of available human studies published since the authoritative documents. One of the studies showed a decrease in blood pressure with increased sodium bicarbonate intake in 10 mildly hypertensive subjects (Ref. 79). For the other subjects in the study and for all subjects during the sodium chloride intake period, the results were inconclusive. The results of the 5-year study involving four simultaneous interventions, the results of the 5-year intervention in two Belgian towns, and the results of the 3-year dietary counseling intervention were also inconclusive (Refs. 42, 70, and 124). However, the large, multinational INTERSALT study (10,079 subjects) (Ref. 37), 11 other recent studies (Refs. 41, 44, 45, 55, 71, 76, 80, 109, 121, 122, and 123), and 5 meta-analyses (Refs. 94, 97, 100, 106, and 107) supported the relationship between sodium intake and blood pressure levels.

F. Summary and Conclusions

There was significant scientific consensus among the three Federal government documents (Refs. 38, 43, and 85), most of the position papers presented at the Federal government workshop (Ref. 103), and the other documents of recognized scientific bodies (Refs. 62, 63, and 108) that high dietary sodium intake, particularly as sodium chloride, is related to the prevalence of hypertension, and that diets that are low in sodium will be

associated with low occurrences of hypertension.

FDA updated the evidence in the documents described above by reviewing the totality of available human studies published since these documents. One study (Ref. 79) was negative in mildly hypertensive subjects, and four studies (Refs. 42, 70, 79, and 124) showed no effect or were inconclusive with respect to a relationship between sodium intake and blood pressure. The other studies (Refs. 37, 41, 44, 45, 55, 71, 76, 80, 94, 97, 100, 106, 107, 109, 121, 122, and 123) supported the conclusions reached in earlier government and authoritative reviews which recognized a link between sodium intake and hypertension. Based on its review, FDA tentatively concludes that the contradictory or inconclusive studies are insufficient to affect the consensus among the government documents and other reviews discussed above.

In summary, the effect of changes in dietary sodium on blood pressure is small but statistically significant. Changes in sodium intake are associated with changes in blood pressure across a wide range of normotensive and hypertensive blood pressures. Thus, reductions in sodium intake have broad applicability. The magnitude of the effect varies widely, with benefit for some but not for all individuals. This variability is typical of nutrient and chronic disease relationships. The responsiveness of some individuals is thought to be the result of a "salt sensitivity"; however, the difficulty in identifying these individuals makes it impractical to predict those individuals most likely to benefit by moderation or reduction in sodium intake. There is some indication that different sodium salts may produce different blood pressure responses, and thus, increasing emphasis is being placed on the potential importance of the chloride ion in combination with the sodium ion in producing blood pressure increases. Additional research is needed in this area. However, because most sodium in foods is in the form of sodium chloride, this issue has little practical impact on public health policies.

G. Tentative Decision To Authorize a Health Claim Relating Sodium and Hypertension

FDA reviewed the publicly available scientific data and authoritative documents on the association between dietary sodium intake and hypertension. On the basis of this review, the agency tentatively concludes that there is significant scientific agreement among experts who by training and experience are qualified to evaluate such evidence to support health claims that high sodium intake is related to the prevalence of hypertension. The basis for this decision is threefold: (1) The strength and the scientific evidence relating high sodium intakes to the prevalence of hypertension; (2) the extent and significance of the likely public health benefit; and (3) the safety of expected dietary changes.

1. Scientific Evidence Is Sufficient to Support the Relationship

Proposed § 101.14(c) states that a health claim may be made if the Secretary determines, "based on the totality of publicly available scientific evidence (including evidence from well designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by the evidence." A companion document, published elsewhere in this issue of the **Federal Register**, considered this requirement and is proposing this standard for health claims for both conventional foods and dietary supplements.

In the case of sodium and hypertension, the "totality of publicly available scientific evidence" included three Federal government documents derived through consensus-building processes (Refs. 38, 43, and 85), a Federal government workshop (Ref. 103), three other documents prepared by recognized scientific bodies (Refs. 62, 63, and 108), one major international epidemiological investigation (Ref. 37), 17 clinical trials (Refs. 41, 42, 44, 45, 55, 70, 71, 76, 79, 80, 94, 97, 109, 121 through 124), and five meta-analyses (Refs. 94, 97, 100, 106, and 107).

In determining whether there was "significant scientific agreement," FDA first looked for consistency in the conclusions and recommendations of the relevant, Federal government documents. The agency then considered the contribution of the Federal government workshop, other recent authoritative documents, and all pertinent human studies available since 1988. In considering the value of particular studies and assessing the quality of the research that produced the data, FDA took into consideration the relevance of study objectives for examining the relationship of sodium to hypertension, the experimental design of the study, the treatment of resultant data, and the statistical significance of the conclusions.

In reviewing the recent primary research, the agency looked for general agreement or disagreement with the conclusions and policy of the Federal government and other comprehensive, authoritative documents and evaluated whether inconsistencies in results from newer studies were sufficient to cause the agency to reverse or modify the conclusions reached in those earlier review documents.

Throughout its evaluation, FDA focused primarily on human studies because the public health issue is hypertension in humans, and especially in Americans. In addition, FDA concentrated on the relationship between the nutrient, sodium, and the disease, hypertension. FDA is aware that a wide range of variables, in addition to sodium intake, have been reported to affect hypertension. Among others, these include chloride, calcium, and magnesium ions; chemical forms of sodium other than sodium chloride; the ratio of serum sodium to serum potassium; alcohol consumption; and obesity. Given the severe time constraints and other specific requirements of the 1990 amendments, FDA limited its evaluation of the scientific data to, the relationship between "sodium" and "hypertension." The agency considered these other issues to be peripheral, and they were addressed only if they related directly to interpretation of the relationship between sodium and hypertension.

In general, the Federal government documents (Refs. 38, 43, and 85), the Federal government workshop (Ref. 103), and the other documents (Refs. 62, 63, and 108) were in agreement that sodium intake specified as sodium chloride in the FASEB document) is related to the prevalence of hypertension. While the effect of the average change in blood pressure in response to sodium restriction is "small" in magnitude, much larger benefit can be expected for persons at greater risk because of already elevated blood pressure levels or because of a predisposition or sensitivity to the adverse effects of salt. Many of the documents noted that there is some indication that, in addition to benefiting many hypertensive individuals, reduced sodium levels may reduce blood pressures and associated risks in some normotensive individuals as well.

In research published subsequent to the documents described above, a few of the human studies showed no effect. However, most of the studies supported the previous conclusions of a link between sodium and hypertension. Thus, the more recent studies were

generally consistent with the conclusions reached by earlier government and authoritative reviews.

FDA tentatively concludes that, having reviewed the relevant, publicly available, scientific evidence, there is significant scientific agreement among experts qualified by scientific training and experience to evaluate claims on a relationship between sodium and hypertension that such claims are supported by the evidence.

2. Public Health Impact

The prevalence of hypertension in the U.S. population is very high, with about one in three adults classified as hypertensive (Ref. 85). As many as 58 million people in the United States have elevated blood pressure (SBP equal to or greater than 140 mm Hg and/or DBP equal to or greater than 90 mm Hg) (Refs. 23 and 38), and only one-quarter to one-third of these individuals have their blood pressure under control (Ref. 74).

Uncontrolled high blood pressure is a serious public health problem because it is associated with mortality from heart disease and stroke, which were ranked as the first and third leading causes of death respectively in the United States in 1987 (Ref. 43). In 1988, 35.3 percent of all deaths were attributable to heart disease and 7.0 percent to stroke (Ref. 82). Individuals with uncontrolled high blood pressure have seven times the risk of developing a stroke and three to four times the risk of developing CHD as persons with normal blood pressure levels (Ref. 74).

Though mortality risk is greatest for hypertensives, normotensives are also at risk, and the higher the blood pressure, the greater the risk (Refs. 69 and 114). A recent, followup, surveillance study of the men screened for the Multiple Risk Factor Intervention Trial (Refs. 68 and 114) showed age-standardized death rate among middle-aged (35 to 57 years of age) U.S. men to be directly proportional to SBP across all blood pressure ranges. Not only did hypertension appear to be a risk factor for premature death, but below average blood pressure appeared to have a beneficial effect on survival. The death rate among hypertensive men (SBP greater than 160 mm Hg) was 41.7 deaths per 1,000; the death rate among those with high normal blood pressure (SBP from 135 to 139 mm Hg) was 20.5 deaths per 1,000; and the death rate among those with low normal blood pressure (SBP from 115 to 119 mm Hg) was 14.9 deaths per 1,000. Because there is a continuum of risk across all blood pressure levels, reducing blood pressure has the potential to benefit the entire population.

In the adult U.S. population, the prevalence of hypertension varies with age, gender, and race (Refs. 27, 43, 57, and 62). High blood pressure and related risks increase sharply with age. Less than 1 percent of individuals under 18 years of age are hypertensive, whereas 23 percent of those from 45 to 64 years of age and 38 percent of those over 65 years of age are hypertensive (Ref. 81). Hypertension commonly occurs in males at a younger age than in females. However, as people age, the prevalence of hypertension increases more rapidly in women and eventually surpasses that of men (Ref. 57). The group with the highest prevalence of hypertension is non-Hispanic blacks, and both males and females are at risk (Refs. 27 and 57). In those over 65 years of age, 52 percent of blacks and 37 percent of whites are hypertensive (Ref. 81).

Changes over time in mean blood pressure and in the prevalence of hypertension have been estimated using data from three large national health surveys. These changes were estimated using an earlier definition of hypertension: SBP equal to or greater than 160 mm Hg and/or DBP equal to or greater than 95 mm Hg and/or currently taking antihypertensive medication (Ref. 27). Although the data from these surveys show that, between 1960 and 1980, the prevalence of hypertension among black adults decreased from 34 to 29 percent, this difference was not statistically significant. There was no decrease of hypertension among white adults during the 20-year period. Average SBP decreased by 5 and 10 mm Hg in white and black adults, respectively. The greatest improvement was among older adults. The data suggest a trend toward lower average blood pressure in the U.S. population that has been attributed to increased public awareness, diagnosis, and treatment. The prevalence of undiagnosed hypertension decreased from 52 to 29 percent, medical treatment of hypertension increased from 30 to 45 percent, and the proportion of individuals with hypertension whose condition was medically controlled increased from 39 to 52 percent.

Recognition of the continuum of mortality risk across all blood pressures prompted recent changes in the clinical definition of hypertension. The current definition identifies hypertension as SBP greater than 140 mm Hg or DBP greater than 90 mm Hg or currently taking antihypertensive medication. Based on this definition, DHHS, in its "Year 2000 Health Objectives for the Nation" (Ref. 74), established a goal for reducing uncontrolled high blood pressure such that at least 50 percent of people with high blood pressure would have their blood pressure under control, a 108 percent increase. Achievement of this goal is expected to have a major effect on reducing the number of deaths from CHD and stroke, two other Year 2000 objectives.

Blood pressure is regulated by a complex process involving multiple factors that are not well understood. Sodium intake, alcohol consumption, and obesity are considered the major dietary factors that influence the development of hypertension in genetically susceptible individuals (Refs. 38, 43, and 62). Nonpharmacological approaches to controlling hypertension have included sodium restriction, alcohol restriction, and weight control (Ref. 29). Thirty to 60 percent of hypertensives and 15 to 45 percent of normotensive individuals respond to sodium reduction and are considered "salt sensitive" (Ref. 116).

The most common source of dietary sodium in the U.S. food supply is sodium chloride or common table salt. The terms "salt" and "sodium" have frequently been used interchangeably although salt (sodium chloride) is only 39 percent sodium by weight. Additional food sources of sodium include sodium bicarbonate or baking soda, baking powder, monosodium glutamate, sodium nitrite, and sodium citrate. Additional sources of sodium include drinking water and sodium-containing drugs (Ref. 16).

In addition to providing sodium to meet nutrient needs of individuals, salt has important uses in foods. Salt is added to a wide variety of foods to enhance and improve flavor. In pickling brines and salted meats, salt helps retard spoilage by inhibiting bacterial growth. In food processing, sodium salts promote curd formation in cheeses, serve as leavening agents in chemically-leavened baked goods, control the growth of yeast in yeast-leavened baked goods, and help to solubilize muscle proteins in some processed meat products (Refs. 6, 7, 8, and 10). Some of the sodium used for these functions can be reduced without unduly affecting the final food product (Ref. 13).

Sodium intake is a small, but significant risk factor for high blood pressure. It has been estimated that reducing sodium intake by 100 mmol per day (2,300 mg) would correspond to an average reduction in SBP and DBP of 2.2 mm Hg and 0.1 mm Hg respectively, on a population basis (Ref. 37), resulting in a 4 percent reduction in CHD mortality

and a 6 percent reduction in stroke mortality each year (Refs. 69 and 114). Assuming a cumulative effect over time, it has been estimated that reducing sodium intake by 100 mmol per day (2,300 mg), from the age of 25 to 55, would correspond to a 16 percent reduction in CHD mortality and a 23 percent reduction in stroke mortality (Refs. 69 and 114). Other estimates suggest that a 50 mmol per day (1,150 mg) reduction in sodium intake, from the age of 50 to 59, would result in a 15 percent reduction in heart disease and a 26 percent reduction in stroke (Ref. 107).

Based on the weight of the evidence that high dietary sodium intake increases the prevalence of high blood pressure, several authoritative groups have recently recommended that Americans reduce or moderate their sodium intake: "Nutrition and Your Health—Dietary Guidelines for Americans" (Ref. 85), "The Surgeon General's Report on Nutrition and Health" (Ref. 43), and "Diet and Health—Implications for Reducing Chronic Disease Risk" (Ref. 62). "Diet and Health—Implications for Reducing Chronic Disease Risk" recommended limiting daily salt intake to 6 g or less (2,400 mg sodium). This recommendation serves as the basis for the proposed DRV for sodium in the proposal on mandatory nutrition labeling published elsewhere in this issue of the **Federal Register**. Current consumption is estimated at between 3,000 and 6,000 mg sodium per day (Refs. 18, 34, 35, and 43), approximately 25 to 150 percent above the maximum level recommended.

It has been estimated that 90 percent of the sodium in foods is from added salt (75 percent added during processing and manufacturing and 15 percent added during preparation and consumption). Therefore, only 10 percent of dietary sodium is attributable to the natural salt and sodium content of foods (Refs. 34 and 35). Because approximately 90 percent of the sodium in foods is added, reduction in sodium consumption is an achievable goal.

FDA has long recognized that sodium is a risk factor contributing to high blood pressure, and the agency first outlined its position concerning sodium and hypertension in 1982 to 1984 in the proposed sodium claim and labeling regulation (47 FR 26580) and in the discussion on the GRAS status of salt (47 FR 26590). FDA concluded that sodium consumption should be reduced in the general population because sodium intake was in excess of biological requirements, that moderate sodium intake would have no adverse effects, and that a large portion of the population would benefit. The agency emphasized that the policy was intended for the general public so that consumers could make informed decisions about their diets.

FDA has monitored sodium labeling since the first Food Label and Package Survey (FLAPS) in 1976 to 1978 (Ref. 25), and sodium education initiatives were included as part of The National High Blood Pressure Education Program, begun in 1981 by FDA and NHLBI (Ref. 47). The labeling and education initiatives resulted in more sodium content labeling on foods (an increase of nearly 60 percent between 1978 and 1988) (Ref. 46), the introduction of more products with lower sodium levels by manufacturers (Ref. 56), greater public awareness of the relationship between sodium and hypertension (up from 12 to 34 percent between 1979 and 1982) (Refs. 47 and 56), an increase in the number of consumers who have seen sodium reduced products and in the number who have purchased such products (Ref. 56), lower sales of table salt (down by 13 percent) (Ref. 47), and an increase in sodium avoidance dieting (practiced by approximately 40 percent of survey population) (Ref. 78).

In conjunction with sodium content in the nutrition label and the use of sodium content claims, the sodium/hypertension health claims, described in this proposal, will provide additional assistance to consumers in implementing the dietary guidelines and in understanding the nature of the relationship between sodium and hypertension. These regulations will be supplemented by extensive, educational initiatives. Such efforts have proven effective in the past in encouraging responsive actions by manufacturers (Refs. 46 and 56), in increasing consumer awareness (Refs. 47 and 56), and in affecting consumer s purchasing habits and behaviors (Refs. 56 and 78).

In summary, because high sodium intake is related to the prevalence of high blood pressure, and because high blood pressure is related to increased risk of heart disease and stroke, reduction and moderation in sodium intake have the potential for having a significant impact on the health of the general U.S. population. Although average changes in salt and sodium intake are associated with changes in average blood pressure that are small in magnitude, the overall potential effect on health care costs and morbidity and mortality rates is quite significant. Persons who are sensitive to sodium would be expected to benefit significantly, and at the recommended levels, there is no apparent risk for those who are not sensitive to sodium Reductions in sodium intake are feasible within current dietary patterns, both through potential changes in food formulations and through the potential for altered consumer awareness and behavior in food selection and in decreased use of discretionary salt.

3. Safety

Minimum average adult requirements for sodium, under conditions of maximum adaptation and without active sweating, have been estimated to be 115 mg per day (Ref. 63). A safe minimum intake has been estimated to be 500 mg per day (Ref. 63), more than three times the minimum requirements. This estimate takes into account wide variations in patterns of physical activity and climatic exposure but does not include an allowance for large amounts of sodium loss from sweating. Current sodium intakes in the U.S. population are thought to be 5 to 10 times higher, well in excess of physiological needs (Refs. 18, 34, 35, and 43).

The DRV proposed for sodium (2,400 mg per day) represents a 20 to 60 percent reduction below current estimates of sodium intake (3,000 to 6,000 mg per day) (Refs. 18, 34, 35, and 43). The DRV is well in excess of the safe minimum intake, and NAS has noted that there is no known advantage in consuming large amounts of sodium (Ref. 63). Reductions in sodium intake, in response to Dietary Guidelines to use salt and sodium in moderation (Ref. 85), to the proposed DRV for sodium, or to sodium/hypertension health claims in this proposed rule, are unlikely to pose a safety risk given the large gap between current intakes (3,000 mg to 6,000 mg sodium per day) and minimum safe levels (500 mg sodium per day) and the wide margin between the proposed goal (2,400 mg sodium per day) and the minimum safe intake levels (500 mg sodium per day).

Sodium is naturally present in many foods, albeit frequently in small amounts. A diet that includes a variety of foods is likely to remain above the minimum safe intake level even without additional salt or sodium being added. Moderate sodium intake, below current consumption levels, is a reasonable public health objective for the general population. This policy would benefit a large segment of the population and would maintain adequate sodium intake for biological functions.

Recommendations to reduce sodium intake are likely to result in reduced chloride intake because sodium chloride, or "salt," is the most common

form of dietary sodium. Reduced chloride intake is not likely to pose a safety concern because dietary chloride deficiencies do not occur under normal circumstances, and the safe minimum intake of chloride was formulated jointly with sodium and salt minimum intakes (Ref. 63).

Of some concern is the loss of sodium as salt during periods of heavy sweating from high temperatures or vigorous physical activity (Ref. 30). Sodium losses can be significant under such conditions and tend to be more severe in individuals who are not acclimated to the temperature or conditioned to the level of activity (Refs. 20 and 30).

Illness can result from heat exhaustion, primarily as a result of salt depletion, and if accompanied by unreplaced fluid losses, can lead to potentially fatal heatstroke (Ref. 30). The concerns over excessive sweat losses led to recent experiments investigating the impact of dietary sodium on the adaptation of soldiers to high temperatures and vigorous exercise (Refs. 117, 118, and 119). Subjects consumed either 4 g salt (1,600 mg sodium) or 8 g salt (3,200 mg sodium) per day, and fluid losses were replaced frequently. Heat acclimation was safely achieved by all subjects, though subjects on the lower salt diet reported more symptoms of heat illness during the first few days, and Johnson (Ref. 118) recommended that higher sodium intakes may be beneficial during the first few days of heat acclimation.

Reports of heat exhaustion tend to involve isolated situations with excessive temperatures or extreme activity levels (Ref. 30). When making health policy recommendations, FDA must balance concerns about hypertension, which affects one third of the U.S. population, against safety concerns under conditions of extreme sweat losses. Heat acclimation was safely achieved on the controlled, low salt diet (1,600 mg sodium per day), and FDA is recommending a DRV for sodium (2,400 mg per day) that is well in excess of 1,600 mg per day. FDA's policy to encourage moderation in sodium intake provides for a wide safety margin. It is the agency's position that concerns about excessive sweat losses should be part of educational efforts aimed at groups that experience heavy physical exertion and especially at those who work with people under conditions of high temperature or vigorous exercise, such as military personnel, sports coaches, and officials involved in exercise programs in hot regions of the nation.

A few studies suggest that some individuals may respond to sodium reduction with blood pressure increases instead of decreases (Refs. 33 and 72). As with many physiological measurements, a heterogeneous distribution may be the result of random variation, especially because the magnitude of the blood pressure lowering effect is small. Additional studies are needed under controlled conditions to determine whether these results are significant and reproducible.

There are a few studies in which plasma lipids were associated with increased sodium restriction (Refs. 40, 49, and 89) and another study that was inconclusive (Ref. 2). The intervention periods in these studies were very short (1 week or less), and the sodium restriction was extreme (460 mg and 780 mg as compared with the 2,400 mg DRV recommended by FDA). FDA believes that these studies are so few in number, so short in duration and conducted under such extremely restricted conditions that they have no bearing on public health recommendations for the general public.

Between 1982 and 1984, FDA concluded that moderate sodium intake would not have any adverse effects on the general public (47 FR 26560). After reviewing the scientific evidence related to sodium and hypertension and the safety issues relevant to moderate dietary sodium, FDA reaffirms that moderate sodium intake is unlikely to pose a safety concern in the U.S. population. Recommendations to moderate sodium intake have been part of public health policy guidelines for more than 10 years (Refs. 9, 22, and 85) with no adverse effects. There is significant agreement among the authoritative documents that moderate sodium intake would not be harmful (Refs. 38, 43, and 62), and serious problems have not been observed in populations that traditionally consume low amounts of salt (Ref. 69). In addition, the review of the scientific evidence indicates that high sodium intakes pose a significant health risk to a large number of people (Refs. 43 and 62).

FDA welcomes any additional information or data on the safety of sodium and salt intake and will continue to monitor the safety implications of all public policy recommendations.

III. Provisional Requirements for Health Claims

A. Relationship

FDA is proposing in § 101.74 to authorize health claims on the relationship of dietary sodium and hypertension on food labels and labeling. The agency has identified several key points that it considers essential for helping consumers to understand this relationship. These points are made in § 101.74(a).

The definition of hypertension used in § 101.74(a) is taken from U.S. DHHS/PHS/NIH reports (Refs. 23 and 38). It defines hypertension as SBP of more than 140 mm HG or DBP of more than 90 mm HG. The regulation also distinguishes sodium from salt.

Proposed § 101.74(a) describes the relationship between sodium and hypertension. Based on its review of the available scientific evidence, FDA states that high sodium intake is related to the prevalence of hypertension and to the increase of blood pressure with age. The agency also states that low sodium intake is related to low prevalence of hypertension and to a low rise or no increase of blood pressure with age.

A substantial amount of human and animal data indicate that high potassium intake may be related to reduced blood pressure levels (Refs. 38, 43, and 62). In addition, high sodium-potassium ratios have been positively correlated with blood pressure levels (Refs. 43 and 62), and NAS (Ref. 62) noted that low sodium intake in combination with high potassium intake "is associated with the lowest blood pressure levels and the lowest frequency of stroke in individuals and populations." FDA considered including potassium intake information in sodium/hypertension health claims. However, because of time and resource constraints, the lack of evidence for a quantitative ratio, and safety concerns involving potassium supplementation and fortification (21 CFR 201.306), FDA at this time has limited the relationship statement to sodium and hypertension. This is the topic that FDA was directed to address in section 3(b)(1)(A)(vi) of the 1990 amendments.

B. Significance

In summarizing the significance of reductions and moderation in sodium intake relative to the reduction in the prevalence of hypertension in the general U.S. population and within the total dietary context, FDA has identified in proposed § 101.74(b) several key points that it considers essential for helping consumers in understanding this nutrient and disease relationship.

This section states that hypertension is a public health concern because it is a risk factor for CHD and stroke. This statement is based on the Surgeon General's Report (Ref. 43) and the NAS Report (Ref. 62). The recognition that there is a continuum of risk across the range of blood pressures, which is reflected in this provision, was

documented in the followup surveillance study of the men screened for the Multiple Risk Factor Intervention Trial (Refs. 68 and 114). The agency has included a statement from Dietary Guidelines on the prevalence of high blood pressure in the United States in this section to provide some indication of the magnitude of the problem and the number of Americans currently affected (Ref. 85).

Based on FDA's evaluation of the scientific evidence, proposed § 101.74(b) goes on to state that reduced sodium intake may benefit some but not all hypertensives and possibly some but not all normotensives. The range of percentages in § 101.74(b) of responsive hypertensive and normotensive individuals that respond to sodium reduction was taken from the Sullivan review (Ref. 116). The regulation recognizes, however, based on the Surgeon General's report (Ref. 43), the NAS report (Ref. 62), and "Dietary Guidelines" (Ref. 85) that there are no practical biological markers for identifying responsive individuals.

The regulation goes on to list the populations most at risk for hypertension and most likely to benefit from sodium reduction. These populations were identified in the Surgeon General's report (Ref. 43), the NAS report (Ref. 62), and the National Health and Nutrition Examination Survey (Ref. 27). It then lists the risk factors for hypertension other than sodium intake. These factors are mentioned in the Surgeon General's report (Ref. 43) and the NAS report (Ref. 62). The statement that the magnitude of the effect is "small" but statistically significant is based on FDA's evaluation of the scientific evidence, which is summarized in section II. of this document. Proposed § 101.74(b) goes on to cite the estimated magnitude of the change in blood pressure in response to a change in dietary sodium intake. The agency took this information from the conclusions of the INTERSALT study (Ref. 37). The estimated reductions in mortality cited in proposed § 101.74(b) were taken from the Stamler's analysis of the impact that the change in blood pressure would have on a population-wide basis (Refs. 69 and 114). This section concludes with recommendations for ways to reduce sodium intake, which were taken from "Dietary Guidelines" (Ref. 85), the Surgeon General's report (Ref. 43), and the NAS report (Ref. 62).

In discussing the magnitude of the effect of a change in sodium intake, the agency uses the words "estimate" and "approximate" to indicate that the values cited are based on the best information available and are close to but not identical to the actual and true values. FDA would consider changing these estimates only if newer estimates that were based on better data and that were significantly different from these values were presented to it.

C. General Requirements

In § 101.74(c)(1), FDA is requiring that for a food to bear a health claim on the topic of sodium and hypertension, it must meet the general requirements for health claims set forth in proposed § 101.14, published elsewhere in this issue of the **Federal Register**. Under this regulation, a sodium/hypertension health claim is prohibited if any of the specified disqualifying nutrient levels are exceeded. This requirement assures that sodium/hypertension health claims may not appear on foods and food products that contain 11.5 g or more of fat per reference amount commonly consumed, per label serving size, or per 100 g, 4 g or more of saturated fat per reference amount commonly consumed, per label serving size, or per 100 g, and 45 mg or more of cholesterol per reference amount commonly consumed, per label serving size, or per 100 g. There are also disqualifying criteria for sodium: 360 mg or more of sodium per reference amount commonly consumed, per label serving size, or per 100 g. However, to qualify to make a sodium/hypertension health claim under proposed § 101.74(c)(2), it must contain 140 mg or less of sodium per serving and per 100 g. A more thorough discussion of the criteria for identifying risk nutrients and the levels of these nutrients allowed in foods that bear health claims is included in the document on general requirements for health claims, published elsewhere in this issue of the **Federal Register**.

The requirement that a food must meet the "low sodium" definition to bear a sodium/hypertension health claim assures that such claims will appear only on foods and food products that contain 140 mg or less of sodium per serving and per 100 g. A more thorough discussion of the "low sodium" criteria and the rationale for the established sodium content levels is presented in the adjectival descriptor document published elsewhere in this issue of the **Federal Register**. Should additional considerations or evidence prompt the establishment of a different definition for "low sodium," only the descriptor document will require revision.

FDA used the qualifying criteria and the disqualifying criteria, described above, to identify foods that would likely be allowed to bear sodium/hypertension health claims (Ref. 93). Examples of foods qualifying for sodium/hypertension health claims include tuna and salmon without added salt; most fruits and vegetables, except for canned and frozen vegetables processed with salt; lowfat milk (2 percent or less fat), evaporated milk, lowfat yogurt with fruit, cottage cheese, ice milk, sherbet, and nondairy dessert toppings and cream substitutes; most flours, meals, grains, and pastas (except for egg pastas); and breakfast cereals such as shredded wheat, low sodium corn flakes, frosted shredded (mini-sized) wheat, puffed rice, sugar crisp, wheat germ, and many prepared cereals such as cream of wheat, cream of rice, and grits. In addition to these types of foods, several other food types would qualify for sodium/hypertension health claims including beverages such as carbonated soft drinks, coffee, tea, some fruit juices, drinks, and punches; some candies, cookies, baked goods, and icings; jams, jellies, and other sweeteners; and margarines and salad dressings without added salt. Given the minimal nutrition value of many of these foods, FDA requests comments as to whether they should be allowed to bear a health claim.

D. Relationship Statement

In the companion document on general principles for health claims published elsewhere in this issue of the **Federal Register**, FDA is proposing to require that claims present an accurate representation of the nutrient/disease relationship. Consequently, based on the scientific evidence regarding the relationship between sodium and hypertension, in § 101.74(c)(2), FDA is proposing that sodium/hypertension health claims must state that a low sodium diet is associated with lower blood pressure in some people, or that a high sodium diet is associated with higher blood pressure in some people. Because sodium reduction helps lower blood pressure in some but not all individuals, FDA is proposing that health claims acknowledge this fact. It is the agency's position that, without such an acknowledgement, the health claim would be misleading to those people whose blood pressures do not respond to sodium reduction.

E. Populations at Greatest Risk and Dietary Risk Factors

In § 101.74(c)(3), FDA is proposing to require that health claims acknowledge that many factors are associated with the development of high blood pressure. Thus, under this proposal, claims will be required to identify high risk populations

and dietary risk factors associated with hypertension. Those most at risk of developing hypertension, and consequently most likely to benefit from sodium restriction, include the elderly and those with family histories of high blood pressure, which may encompass individuals in specific racial or gender groups (Refs. 27, 43, 57, and 62). In addition to dietary sodium intake, alcohol consumption and obesity are identified, modifiable, dietary risk factors for hypertension (Refs. 43 and 62). Consequently, achieving weight control and reducing alcohol consumption have been recommended to assist in lowering blood pressure levels in the general population (Ref. 85). This additional information on populations and risk factors provides a broader context for the nutrient/disease relationship. Presentation of this information will ensure that consumers are aware that, in addition to sodium intake, there are many other factors that contribute to the development and control of hypertension.

IV. Optional Health Claim Information

A. Sodium as an Essential Nutrient

Sodium is an essential nutrient, and it is important that consumers include sodium in their total diets. On the other hand, NAS has recommended a safe, minimum level of 500 mg sodium per day (Ref. 63) and an upper limit of 2,400 mg sodium per day (Ref. 62). Elsewhere, in this issue of the **Federal Register**, FDA is proposing to establish a DRV for sodium of 2,400 mg per day for use in nutrition labeling. Yet, while some sodium is required for good health, excessive intake of sodium is unnecessary and may be harmful. For consumers to understand the significance of the sodium contained in a food that is qualified to bear a sodium/hypertension health claim in relation to the total daily intake goal, FDA considered requiring that sodium/hypertension health claims state that adults should consume at least 500 mg but not more than 2,400 mg sodium per day. However, in an attempt to keep health claims short and not overwhelm consumers with information, FDA is tentatively proposing in § 101.74(d) (1) to allow, but not to require, quantitative limits for sodium intake. The agency requests comments on whether this additional information will be beneficial to consumers, and whether it should be required on health claims or remain optional.

B. Consultation of Physicians

Many people are now aware of the dangers of high blood pressure (Ref. 56). With the ready availability of "do it yourself" machines to measure blood pressure levels in grocery stores and shopping malls and the common practice of having blood pressure levels checked each time an individual visits a physician or health professional, many people now know what their blood pressure levels are. FDA is concerned that some individuals may attempt to use the ready-availability of sodium labeling, and in particular sodium/hypertension health claims, to self-medicate or treat their hypertension without consulting a physician. For this reason, the agency considered requiring that health claims state that individuals with high blood pressure should consult their physician for specific medical advice and guidance.

Health claims that result from this regulation are intended for the general healthy public, however. Hypertension is a serious medical condition. It is FDA's view that any individual with an identified medical problem should be under the care of a physician, and that health claims are not intended as a substitute for individual patient/doctor care and especially not for individuals with identified medical diseases or health-related conditions. The agency has tentatively decided to include this information as an optional element, § 101.74(d) (2), and requests comments.

C. Sodium and Salt

FDA is proposing in § 101.74(d) (3), to allow manufacturers to use the term "salt" in addition to the term "sodium," both of which have been incorporated into "Dietary Guidelines" to use salt and sodium in moderation. Salt, which is 39 percent sodium by weight, is the most common source of dietary sodium and is a more familiar term to the general public than sodium. A recent FDA survey found that approximately 70 percent of the survey population generally understood that sodium and salt are related (Ref. 1982). Respondents frequently used "sodium" and "salt" interchangeably, which is technically incorrect but functionally effective because reducing salt intake also reduces sodium intake. The available evidence suggests, however, that sodium is the nutrient most clearly implicated in hypertension. Furthermore, in the proposed nutrition labeling document published elsewhere in this issue of the **Federal Register**, FDA is proposing to use the term "sodium" in the nutrition label to inform consumers of the sodium content of a food. Therefore, allowing use of the term "salt" in a sodium/hypertension health claim, rather than the term "sodium," would be potentially confusing to consumers because it would be inconsistent both with the nutrition label and with the strongest scientific evidence for linking dietary factors to hypertension. Conversely, using the term "salt" in addition to the term "sodium" would seem less likely to be misleading and may actually be useful to those consumers who are unfamiliar with the more technical term but who wish to reduce their sodium intake. Therefore, the agency is proposing to allow the use of the term "salt" if the term "sodium" is also used.

The agency is aware that a few recent studies and reviews suggest that the chloride ion, rather than or in addition to the sodium ion, may be important in the development of high blood pressure (Refs. 31, 48, 79, 87, and 92). Early studies with sodium chloride attributed blood pressure increases to the chloride ion; however, in the 1950's the sodium ion was considered to be more important (Refs. 14 and 43). Because many of the studies that investigated the relationship between sodium and hypertension used sodium chloride as the source of dietary sodium, these studies do not distinguish the effects of sodium from the effects of sodium chloride.

In the early and mid-1980's, studies with various sodium salts found that while sodium chloride raised blood pressure levels in sensitive individuals and animals, other sodium salts had no effect (Refs. 31 and 43). The recent studies (Refs. 79 and 87) are inconclusive with respect to chloride or indicate that the sodium and chloride ions have different roles. Recent reviews (Refs. 48 and 92) suggest that sodium and chloride together produce larger blood pressure changes, and that the ion that is associated with the sodium may greatly influence the subsequent blood pressure response. To date, the studies involving humans have been few in number and small in size. Consequently, at this time, there is insufficient information available for drawing substantive conclusions or for changing public health policy recommendations. Nonetheless, these results raise important questions, and FDA encourages additional research to determine the independent and combined effect of sodium and of chloride on blood pressure.

Sodium chloride is the major source of dietary sodium. Because FDA's policy of encouraging sodium reduction will also result in chloride reduction, the policy remains prudent regardless of whether sodium, chloride, or sodium chloride is determined to be important in relationship to hypertension. In addition, compliance is simplified because sodium content is identified on the labeling and

verification would involve detection of sodium alone. The agency requests data and comments on the appropriateness of selecting sodium rather than sodium chloride as the specified nutrient and on the appropriateness of allowing the term "salt" in addition to the term "sodium" on sodium/hypertention health claims.

D. High Blood Pressure and Hypertension

In § 101.74(d)(4), FDA is proposing to allow manufacturers to use the term "hypertension" in addition to the term "high blood pressure." Hypertension is a broader term which encompasses persons with untreated high blood pressure levels as well as persons with "normal" levels as a result of effective treatment. Hypertension is also the disease specified in section 3(b)(1)(A)(vi) of the 1990 amendments. The term "high blood pressure" means nearly the same thing as hypertension and individuals with controlled high blood pressure are frequently considered to have high blood pressure even though, technically, the blood pressure levels are in the normal range. The term "high blood pressure" is less technical and more familiar to consumers since blood pressure measurement is included in routine physical examinations, and blood pressure response is used to monitor the treatment of hypertension. Because simple, uncomplicated terminology is useful for assuring that health claims are clear and understandable to consumers, FDA is proposing to require the use of the term "high blood pressure" and to allow for the optional addition of the term "hypertension." The agency requests comments on the appropriateness of this proposed usage.

E. Additional Information

In § 101.74(d)(5), FDA is proposing to allow manufacturers to develop sodium/hypertension health claims that provide factual information about hypertension, including information contained in the "Relationship" and "Significance" statements included as part of the regulation and estimates of the number of people in the United States who are affected with high blood pressure or hypertension. It is FDA's policy that one of the purposes of health claims is to inform and educate the general public. Consequently, manufacturers should be allowed to include accurate, factual information in their health claims about the prevalence and seriousness of hypertension for the U.S. population. FDA is proposing to limit the additional information allowed to that contained in these statements because they are based on FDA's review of the scientific evidence concerning sodium and hypertension. By using an approximate estimate of prevalence, such as "one in three" adults, updating this estimate is likely to be less of a problem than if a more precise estimate were used.

F. Model Health Claim

FDA is including in proposed § 101.74(c) a model health claim on sodium and hypertension. The agency is including this model to assist manufacturers in formulating an appropriate claim.

V. Environmental Impact

The agency has determined under 21 CFR 25.24(a) (11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VI. Effective Date

FDA is proposing to make these regulations effective 6 months after the publication of a final rule based on this proposal.

VII. Comments

Interested persons may, on or before February 25, 1992, submit to the Dockets Management Branch (address above) written comments regarding this proposal. Two copies of any comments are to be submitted, except that individuals may submit one copy. Comments are to be identified with the docket number found in brackets in the heading of this document. Received comments may be seen in the office above between 9 a.m. and 4 p.m., Monday through Friday.

VIII. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96-354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**. The agency requests comments on the RIA.

Appendix to the Preamble—Consumer Health Message Summary—Sodium and High Blood Pressure

The following Appendix is a proposed consumer summary on sodium and hypertension. FDA solicits comments on this document as explained in the proposal on the general requirements for health claims published elsewhere in this issue of the **Federal Register**.

Appendix—Consumer Summary on Sodium and High Blood Pressure

Sodium and High Blood Pressure

Under the provisions of the recent Nutrition Labeling and Education Act of 1990, manufacturers may put clear information on the food label about the relationship between a nutrient, such as sodium, and a disease or health-related condition, such as hypertension. To prevent consumers from being misled, FDA allows only truthful label statements about diet and health relationships that are firmly supported by the current scientific evidence. There is agreement that the scientific evidence is strong enough to allow health claims about the relationship between sodium in the diet and hypertension.

Many consumers have said that health claims on food labels could be useful to them in making improvements in their diets. However, label space is often limited. Therefore, the label statement may refer to an attached pamphlet, or other adjacent labeling that provides additional information about the health claims that appear on the label of the food product itself.

In addition to allowing health claims about the relationship between sodium and hypertension, FDA is allowing health claims about the relationship between calcium and osteoporosis, saturated fat and cholesterol and cardiovascular disease, and fat and cancer. For information about these other diet and health relationships, write to: (to be supplied by manufacturer).

What is Hypertension?

Hypertension means high blood pressure, a condition in which your blood pressure goes up and stays above a normal level. Blood pressure measures the force of blood against the artery walls as the heart pumps blood through the body.

When you get your blood pressure checked, you are given two numbers. The first number (systolic pressure) is the force of blood against the artery walls when the heart beats. The second number (diastolic pressure) is the force on the artery walls when the heart relaxes between beats. Currently, people with systolic blood pressure of 140 or more millimeters of mercury (mm Hg) and/or diastolic blood pressure of 90 or more mm Hg are considered to have high blood pressure.

Why is There Concern About Hypertension?

In the United States, about one in three adults has high blood pressure. The disease affects approximately 58 million people and is a public health concern primarily because it is a major risk factor for death from coronary heart disease and stroke. Risk of death increases steadily as blood pressure increases. People with high blood pressure levels are at greatest risk, and the lower the blood pressure the lower the risk.

Hypertension occurs more frequently among persons with a family history of high blood pressure, elderly men and women of all races, black men and women, and men at an earlier age than women. In the U.S., hypertension and its related risks increase with age. Less than 1 percent of people below age 18, about 23 percent of people between ages 45 through 64, and about 38 percent of people over 65 have hypertension.

Primarily because of increased public awareness and treatment of the disease, hypertension has decreased somewhat in the U.S. population in recent years; nevertheless it remains a serious public health concern.

What Is the Cause of Hypertension?

In most people with high blood pressure the cause is unknown. Regulation of blood pressure by the body is a complex process that is not completely understood. Probably a variety of factors influence the development of hypertension in people whose heredity makes them susceptible to the disease.

Currently, scientists generally agree that three major diet-related factors have an effect on blood pressure—obesity or being overweight, excessive sodium in the diet, and excessive alcohol consumption.

The terms "salt" and "sodium" often are used interchangeably, although salt (which is sodium chloride) is only part sodium. Salt is our most common source of dietary sodium.

Studies of populations around the world provide the primary basis for associating dietary sodium with hypertension. In populations that have diets low in sodium, high blood pressure is less common than in populations with diets high in sodium. Scientists believe that dietary sodium is related to hypertension, and that diets which are lower in sodium will be associated with lower frequency of hypertension.

These studies also indicate, that in populations with diets low in sodium, blood pressure increases less rapidly or does not increase at all with age. This contrasts sharply with the blood pressure increases with age that are seen in the U.S. Less salt in the diet may be particularly appropriate for people who are at increased risk for developing hypertension in later life, such as blacks and those with either a family history of high blood pressure or current high normal blood pressure levels. The blood pressure of some—but not all—people will be lowered by decreasing dietary sodium. Persons whose blood pressure is decreased by lowering sodium are considered "salt sensitive." There is no practical way to identify the "salt-sensitive" people in the population, to predict who might develop high blood pressure, or to determine who will benefit from reducing dietary sodium. Authorities currently recommend that most people use salt and sodium only in moderation. Reduction in sodium will benefit those people whose blood pressure rises with high salt intake. No harmful effect is known to occur from moderately reducing dietary sodium.

Do Most People Eat Too Much Salt and Sodium?

Sodium is an essential nutrient that is required by the body. The National Academy of Sciences has set a minimum safe amount for adults of 500 milligrams (mg) per day under normal temperature and activity conditions. People who lose a lot of sodium and water through sweat need to drink extra water and in rare cases replace the lost salt. The Academy has stated that there is no known advantage in consuming large amounts of sodium in excess of body needs. Most Americans consume several times the minimum amount of sodium needed.

The U.S. Public Health Service has set a national health goal for the public to use salt and sodium in moderation. To do this, people are encouraged to prepare foods without adding salt, to avoid salt at the table, and to make a habit of purchasing foods that are low in sodium or modified to lower sodium content.

Which Foods Are Sources of Sodium?

Sodium in the diet comes from many sources. Small amounts of sodium are found naturally in many foods, so if you eat a variety of foods, you'll easily get the minimum safe amount.

However, your salt intake can increase dramatically depending on the choices you make. Salt is added for flavoring and preserving during processing of many foods, but products are often available in a "low sodium" version as well. Salt may also be added during cooking at home, or by yourself at the table. In addition to table salt, many substances added to foods, such as baking soda, baking powder, sodium nitrite, and monosodium glutamate (MSG), contain sodium.

A good way to learn about the amount of sodium in foods is to read nutrition labels. Most foods now have nutrition information on their labels. The amount of sodium in a serving of food is listed in milligrams. FDA has established "Daily Values" for several nutrients, including sodium, that are important in diet and health relationships. The daily value is intended to help consumers determine how a single serving of a food contributes to the total amount of nutrient for the day. The daily value for sodium is 2,400 mg, based on a report from the National Academy of Science. Therefore, a food that contains 600 mg sodium per serving would provide about one-quarter of the daily recommended value for sodium. When you add up the sodium from all the foods you eat in a day, it should total less than 2,400 mg.

What Do Label Claims About Sodium Mean?

In addition to the amount of sodium per serving on the nutrition label, you may see other kinds of claims about sodium on some food packages. There are two kinds of label claims—nutrient content claims and health claims.

Nutrient content claims may be made about the amount of sodium the food contains. For example, a food that contains 35 mg sodium or less per serving may be labeled "very low sodium." Foods that contain 5 mg or less of sodium per serving may be labeled "sodium free" or "no sodium," and foods that contain 140 mg sodium or less per serving may be labeled "low sodium." A reduced sodium claim on a food label indicates that the sodium content has been reduced by 50 percent or more compared to the regular product.

Some foods that are low in sodium may contain one or more nutrients that may increase the risk of a diet-related disease other than high blood pressure. For example, a low sodium food could be high in saturated fat which has a relationship to elevated blood cholesterol and heart disease. A content claim about sodium cannot be made on such foods without indicating the presence of the other nutrient, for example, "Low, sodium; see nutrition label for saturated fat content."

Health claims are those made about the relationship between the nutrient, sodium, and the disease, hypertension. Health claims of this type may appear only on foods that qualify as "low sodium." In addition, the food must not contain any other nutrient that FDA has determined increases the risk of a diet-

related disease or health condition other than hypertension. For example, a health claim could not appear on a "low sodium" food that contains a high amount of saturated fat, because saturated fat has a relationship to heart disease.

Many foods are eligible to make sodium and hypertension claims. For example, at least some products in each of the following categories of foods can make such claims: Fruits and vegetables; fruit juices and drinks; milk and dairy products; breakfast cereals; cereal grains (such as rice); pasta products (such as spaghetti); flours; legumes (peas and beans); nuts and seeds; and seafood.

Other Diet-Related Risk Factors for Hypertension

In addition to sodium, there are at least two other diet-related factors for hypertension over which a person has control—body weight and alcohol consumption. Increased body weight is related to increased blood pressure, and blood pressure falls when weight is reduced. Weight loss is recommended for all overweight persons, particularly those with hypertension. People who regularly consume large amounts of alcohol have higher blood pressure than people who don't drink or who drink only in moderation. Authorities recommend maintaining a healthy weight and drinking alcoholic beverages in moderation, if at all.

Facts to Keep in Mind

It's the total combination of foods that you eat regularly— both the kinds and the amounts—that's important in terms of good nutrition. Eating particular foods or one specific food isn't a magic key that will assure you have a more healthy diet.

Eating a healthy diet, in itself, doesn't guarantee good health. A healthy diet, however, is an important part of a healthy lifestyle that includes, for example, regular physical exercise, not smoking, not drinking alcoholic beverages to excess, and not abusing drugs.

In addition to what you eat, many factors may affect your own chance of developing a particular disease. Among these are your heredity, your environment, and the health care you receive. Our knowledge about most diet-health relationships is incomplete and will improve as scientific knowledge increases. However, enough is known today about some of these relationships to encourage specific dietary practices that are believed to be beneficial.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under the authority delegated to the Commissioner of Food and Drugs, it is proposed that 21 CFR part 101 be amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR Part 101 is revised to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 501, 502, 505, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 351, 352, 355, 371).

2. Section 101.74 is added to subpart E to read as follows:

§ 101.74 Health claims: sodium and high blood pressure.

(a) *Relationship between sodium and high blood pressure.*

As used here, hypertension, or high blood pressure, means systolic blood pressure of greater than 140 millimeters of mercury (mm Hg) or diastolic blood pressure of greater than 90 mm Hg. Normotension, or normal blood pressure, is a systolic blood pressure below 140 mm Hg and diastolic blood pressure below 90 mm Hg. Sodium is specified here as the chemical entity or mineral "sodium" and is distinguished from sodium chloride or salt, which is 39 percent sodium by weight. The scientific evidence from epidemiological, clinical, and animal data establishes that high sodium intake is related to the prevalence of hypertension or high blood pressure and to the increase of blood pressure with age, and that low sodium intake is related to low prevalence of hypertension or high blood pressure and to a low rise or no increase of blood pressure with age.

(b) *Significance of sodium in affecting high blood pressure.* High blood pressure is a public health concern primarily because it is a major risk factor for mortality from coronary heart disease and stroke. There is a continuum of mortality risk that increases as blood pressures rise. Individuals with high blood pressure are at greatest risk, and individuals with moderately high, high normal, and normal blood pressure are at steadily decreasing risk. The 1990 "Dietary Guidelines for Americans" states that: "In the United States, about one in three adults has high blood pressure." The scientific evidence from clinical data indicates that reducing sodium intake lowers blood pressure and associated risks in some but not all hypertensive individuals; approximately 30 to 60 percent respond to sodium reduction. There is some evidence that reducing sodium intake lowers blood pressure and associated risks in many but not all normotensive individuals as well: approximately 15 to 45 percent respond to sodium reduction. There are no practical genetic markers to identify responsive individuals. The populations at greatest risk for high blood pressure, and those most likely to benefit from sodium reduction, include those with family histories of high blood pressure, the elderly of all genders and races, males because they develop hypertension earlier in life, and black males and females. Sodium intake, alcohol consumption, and obesity are identified risk factors for high blood pressure. On a population-wide basis, the indications from epidemiological and clinical data are that reducing the average sodium intake would have a small but statistically significant effect on reducing the average blood pressure. Estimates suggest that reducing sodium intake by 100 millimoles (mmol) per day (2,300 mg of sodium or approximately one rounded teaspoon of salt) would correspond to an average lowering of blood pressure of approximately 2.2 mm Hg systolic and 0.1 mm Hg diastolic. Because these are population-wide estimates, the magnitude of the effect for sensitive individuals would be greater. Estimates suggest that, for the age range from 25 to 55, a 100 mmol per day (2,300 milligrams (mg) per day) lower lifetime intake of sodium would correspond to a reduction in mortality rates of approximately 16 percent for coronary heart disease and 23 percent for stroke. In order to reduce sodium intake, individuals can choose foods with less sodium and salt, reduce the amount of sodium and salt used in food preparation and cooking, and reduce the amount of salt added at the table.

(c) *Specific requirements.* A food label or labeling may contain a sodium/hypertension health claim provided that:

(1) The health claim for a food or food product meets all the general requirements of § 101.14 for health claims.

(2) The health claim states that a low sodium diet is associated with or related to lower blood pressure in some people. Alternatively, the health claim can state that a high sodium diet is associated with or related to higher blood pressure in some people.

(3) The health claim identifies the populations at greatest risk of developing high blood pressure as being the elderly and those with family histories of high blood pressure and states that other dietary risk factors associated with high blood pressure include alcohol consumption and excess weight.

(d) *Optional information.* Sodium/hypertension in health claims may provide additional information:

(1) The health claim may state that sodium is an essential nutrient or necessary for good health, and that the total intake of sodium should be at least 500 mg per day but not more than 2,400 mg per day.

(2) The health claim may state that individuals with high blood pressure should consult their physicians for medical advice and treatment.

(3) In specifying the nutrient, the health claim may include the term "salt" in addition to the term "sodium".

(4) In specifying the disease, the health claim may include the term "hypertension" in addition to the term "high blood pressure".

(5) The health claim may include information from paragraphs (a) and (b)

of this section, which include summaries of the relationship between sodium and high blood pressure and of the significance of sodium reduction in affecting high blood pressure.

(e) *Sample health claim.* High blood pressure is associated with many factors, including a family history of the disease, growing older, being overweight, drinking too much alcohol, and diets high in sodium. A low sodium diet is associated with lower blood pressure in some people.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

TABLE 1.—INTERSALT STUDIES

Reference	Study design and duration	Subjects	Base diet	Other factors	Results	Assessment and comments
INTERSALT Cooperative Research Group (1988). (Ref. 37)	Cross sectional study. Sodium (Na) intake determined by single 24-hour urine collection blood pressure determined by average of 2 seated measurements. Repeated urine collections for 8% of subjects to estimate within-individual variability.	10,079 subjects from 52 population centers in 32 countries. (5,045 males, 5,034 females). (Goal of 200 at each center, 25 in each of 8 age and sex groups).	Normal diets ranging from 5 mg Na per day to 5,560 mg Na per day.	Single Na measurement does not assess previous or habitual Na intake habits. Subjects on antihypertensive medication included thereby reducing the effect of Na on blood pressure. Urine collection probably not complete in all subjects. Confounding factors: age, sex, body mass index, alcohol intake, and potassium intake. Significance sometimes lost after adjustment for confounding factors.	Within centers: Na significantly related to SBP and DBP. Across 52 centers Na significantly related to SBP, to DBP, and to changes in SBP and DBP with age. Across 48 centers: Na significantly related to change in DBP with age and significantly and negatively related to DBP. Estimated that 2300 mg less Na per day corresponds to lower SBP (2.2 mm Hg), lower DBP (0.1 mm Hg), and lower change of SBP (9.0 mm Hg) and DBP (4.5 mm Hg) with age from 25 to 45 years of age.	Large scale International Standard assessments Little data loss (approximately 3%). Study methods consistent within and across populations. Within center relationships and across center changes in relationships with age were consistent. Across center relationships depended on inclusion or exclusion of 4 population centers.
Elliott (1989)..... (Ref. 50)	INTERSALT study design. Analysis of normotensive subjects.	Normotensive subjects from INTERSALT population (SBP < 140 mm Hg, DBP < 90 mm Hg, not on antihypertensive medication).	Normal diets	Multiple regression analysis adjusted for age, sex, potassium intake, alcohol intake, and body mass index. Corrected for individual variability of Na excretion ("reliability") (see below).	Na intake significantly related to blood pressure: 2300 mg change in Na intake corresponded to 2.10 mm Hg change in SBP after multiple regression analysis to adjust for confounding factors.	Regression coefficient similar to findings with the total INTERSALT population. Total population: 2300 mg change in Na intake corresponded to 2.17 mm Hg change in SBP.
Elliott (1989)..... (Ref. 51)	INTERSALT study design. Analysis of all INTERSALT data by age and sex.	10,079 subjects: (5045 males, 5034 females). (Goal of 100 males and 100 females from each of 52 centers, 25 in each age category: 20–29, 30–39, 40–49, and 50–59).	Same as INTERSALT.....	Multiple linear regression analyses in 52 centers, pooled, weighted, adjusted for potassium intake, alcohol intake, and body mass index, and adjusted for age or sex as appropriate. Corrected for individual variability of Na excretion ("reliability") by estimating the degree of regression dilution using data from 8% of subjects who returned and provided second set of data.	Within centers: Average Na intake related to SBP and DBP in men and in women, to SBP for men and women combined in 4 age categories, and to DBP in only the oldest age category. Across centers associations influenced by 4 centers with low Na intake.	Associations stronger for women than for men and for the older age categories.
Elliott (1989)..... (Ref. 52)	INTERSALT study design. Main results and implications for public health policy.	Same as INTERSALT.....	Same as INTERSALT.....	Some subjects were on antihypertensive medication which would give artificially low blood measurements and underestimate any effect of Na on blood pressure. Only simple adjustments were used to correct for bias toward zero. Some populations had been subjected to health campaigns to reduce Na intake which would underestimate current blood pressure effects due to previous habits.	The higher the center's median Na excretion, the steeper the slope of blood pressure with age.	Authors suggest that small clinical changes could result in large benefits to a population, especially in the cumulative effects over a lifetime. Authors conclude that the study gave "powerful *qualitative* tests . . . poor *quantitative* estimates of the size of these relationships."
Elliott (1989)..... (Ref. 53)	INTERSALT study design. Analysis of data from three United Kingdom centers (Belfast, Birmingham, and South Wales). Data collection in 1985.	598 subjects: (299 men, 299 women)	Normal diets Na ranging from 730 mg to 9,040 mg per 24 hours. Averages: Belfast: 3,470 mg Na per 24 hours. Birmingham: 3520 mg Na per 24 hours. South Wales: 3500 mg Na per 24 hours.	43 subjects excluded (41 for incomplete urine collection and 2 for pregnancy).	SBP positive and significantly related to Na in 2 of 3 centers ($p<0.05$) (Belfast, South Wales) and inconclusive in third. DBP relationship inconclusive in 3 centers.	Authors recommend modest increase in K and reductions in Na, obesity, and heavy alcohol drinking and suggest these lifestyle changes could result in downward shift of population blood pressure and prevalence of hypertension.

Hashimoto (1989)... (Ref. 54)	INTERSALT study design. Analysis of data from three Japanese centers (urban Osaka, rural Tochigi, semi-rural Toyama).	591 subjects: (295 men, 296 women)	Normal diets Average Na of 4,300 mg per 24 hours Averages: Osaka: 3,870 mg Na per 24 hours. Tochigi: 4,150 mg Na per 24 hours. Toyama: 4,890 mg Na per 24 hours.	9 subjects excluded for incomplete data. High within-individual variation. Public health campaigns to reduce Na intake resulted in declines in Na consumption, Blood Pressure, prevalence of hypertension, and stroke mortality. 16.7 normotensives and 47.4 hypertensives receiving medical treatment reported reducing salt intake.	SBP negative and significantly related to Na in 1 center ($p<0.001$). (Osaka), positive and significantly related to Na in 1 center ($p<0.05$). (Toyama) and inconclusive in third DBP negative and significantly related to Na in 1 center ($p<0.01$). (Osaka) and inconclusive in other two.	Authors recommend further reductions in Na, increases in K, and reductions in heavy drinking.
Mancilla-Carvalho (1989). (Ref. 58)	INTERSALT study design. Analysis of data from four remote populations with low ??? (NaCl) intake. (Yanomano and Xingu Indians in Brazil, rural Kenya, and rural Papua New Guinea).	731 subjects: Yanomano Indians: 195 subjects. Xingu Indians: 198 subjects. Papua New Guinea: 162 subjects Kenya: 176 subjects	Normal diets ..... Median Na: tanomano Indians: 5 mg Na per 24 hours. Xingu Indians: 130 mg Na per 24 hours. Papua New Guinea: 620 mg Na per 24 hours. Kenya: 1,180 mg Na per 24 hours.	Average body weight low relative to other 48 centers. No or low average alcohol intake. Group variability largest in Kenya population. Authors noted that within-center association between Na and blood pressure was unlikely due to small variations in average Na and blood pressure. Adults were physically active and healthy with no signs of malnutrition or protein deficiency.	Four populations had lowest average blood pressure compared to other 48 centers (SBP of 103 mm Hg vs 120 mm Hg, DBP of 63 mm Hg vs 74 mm Hg). Four populations had little or no upward slope of blood pressure with age. Hypertension in 5% of Kenyan population and absent in other populations. Four populations had low average Na relative to other 48 centers (1-3 grams NaCl vs 9 grams NaCl).	Authors noted that when other centers had low average body weights and alcohol intake, but high Na intake (2,760 to 4,830 mg), the prevalence of hypertension ranged from 8 to 19%.
Mancilla-Carvalho (1989). (Ref. 59)	INTERSALT study design. Analysis of data from Yanomano Indians, a seminomadic population from the Brazilian, Amazon rainforests. Data collected July 1986.	195 subjects: (99 males, 96 females)	Normal diets ..... Average Na of 21 mg per 24 hours. Range from 1 mg to 614 mg per 24 hours. Diet of local crops and game supplemented by wild fruits and insects. Banana and manioc staple foods. Little salt, refined sugar, alcohol, milk or dairy products in diet.	Low average body mass index, calcium intake, total fat and saturated fat. High K intake, fiber. No alcohol intake. Almost no obesity. Relatively high physical activity and endurance. No physical signs of evident malnutrition or protein deficiency. Na not considered in correlation analysis because non-normal distribution made it inappropriate. May have eaten some food from investigators.	Average SBP 96.0 mm Hg (range from 78 to 128 mm Hg). Average DBP 60.6 mm Hg (range from 37 to 86 mm Hg). Low average blood pressure. No hypertension. No increases of blood pressure with age.	
Rose (1989) ..... (Ref. 64)	INTERSALT study design. Summary of background, methods, and main results. Designed to apply highly standardized methods across varied populations, to examine major confounding factors, and to evaluate the relationships in individuals.	INTERSALT populations	Same as INTERSALT	Planned study to be large enough to observe an effect. Planned standardized methods to allow for appropriate pooling of results. Planned analysis methodology to deal with confounding factors. Planned random repeat urine collections to estimate within-individual variability ("reliability").	Na excretion significantly related to blood pressure in individuals and to rise of blood pressure with age.	2 years for planning, funding, and recruitment of centers. Regional training meetings in 1984-1985. Field work and laboratory analyses completed in 1987.

TABLE 2.—SODIUM/HYPERTENSION STUDIES

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
Australian National Health and Medical Research Council Dietary Salt Study Management Committee (1989a). (Ref. 44).....	Double blind, placebo controlled, clinical intervention trial. 6 weeks: run-in phase. 8 weeks: diet phase. Subjects seen every 2 weeks and 24-hr urine provided at each visit. During diet phase, all subjects monitored and counseled to keep dietary Na intake to below 1840 mg Na per day. NaCl or placebo added to low Na base diet.	103 mildly hypertensive subjects (DBP: 90–100 mm Hg). (86 male, 17 female). (Average age: 58.4 years). Randomized into two groups.	Study population: 8 (10 mmol) slow release NaCl tablets per day. Control population: 8 placebo tablets per day.	1840 mg Na per day.	Low Na diet (< 1840 mg Na per day monitored by 24-hr urine collection and dietary counseling).	2 centers..... 8 subjects dropped out. Large range of individual variation SBP of study and control populations approached same value near end of study DBP of study and control populations approached each other but remained distinct at end of study. Confounding factors: age, sex, weight, initial blood pressure, center.	Blood pressure of low Na group reduced an average 6.1 (SBP) and 3.7 (DBP) mm Hg in the study population relative to 0.6 (SBP) and 0.9 (DBP) mm Hg reduction in the control population ($p<0.005$). Results remained significant after multi-variant analysis to adjust for age, weight, and initial blood pressure.	Sound methodology Skewed sex ratio, but approximately equal distribution to each group Dietary Na restriction produced heterogeneous response in individuals, but confirmatory studies in "responder" and "nonresponder" populations have not been done.
Australian National Health and Medical Research Council Dietary Salt Study Management Committee (1989b). (Ref. 45).....	Double blind, placebo controlled, clinical intervention trial. Continuation of previous study and study design to include crossover phase. 6 weeks: run-in phase. 8 weeks: diet phase 1. 8 weeks: diet phase 2.	88 mildly hypertensive subjects (DBP: 90–100 mm Hg). (73 male, 15 female). (Average age: 58.6 years). Randomized into two groups.	Study population: 8 (10mmol) slow release NaCl tablets per day. Control population: 8 placebo tablets per day.	1840 mg Na per day.	Low Na diet (< 1840 mg Na per day monitored by 24-hr urine collection and dietary counseling).	2 centers..... 15 subjects dropped out between two diet phases. 79 subjects completed study. Confounding factors: age, sex, weight, initial blood pressure, center, order of treatment.	Blood pressure of low Na group reduced an average 6.0 (SBP) and 4.1 (DBP) mm Hg in the study population relative to 0.1 (SBP) and 0.4 (DBP) mm Hg reduction in the control population ($p<0.001$). Blood pressure reduced an average 3.6 (SBP) and 2.1 (DBP) mm Hg in the NaCl diet phase vs the placebo diet phase. Differences independent of order of treatment. Statistical significance greater for DBP than for SBP.	Sound methodology

TABLE 2.—SODIUM/HYPERTENSION STUDIES—Continued

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
Dustan (1989). (Ref. 121) ..	Clinical intervention trial. Protocol 1: 3 days: Control phase, 4 days: Na depletion phase, 3 days: Na loading phase. Protocol 2: 3 days: Control phase, 3 days: Na loading phase, 4 days: Na depletion phase. Na determined by 24-hour urine excretion blood pressure determined 4 times per day.	Protocol 1: 69 normotensives and 21 hypertensives. Protocol 2: 27 normotensives and 19 hypertensives. 12 normotensives and 9 hypertensives participated in both protocols. Hypertensives were either untreated or had not received antihypertensive medication for at least 1 month.	Na depletion phase: Furosemide (1 mg per kg) taken as 2 divided doses. Na loading phase: Isotonic saline (3.88 mM NaCl per kg per day) supplied intravenously over 4 hrs.	Na loading phase: 90 mg Na per kg per day.	Controlled diets. Control phase: 3450 mg Na per day (assumed as diet since was not clear). Na depletion and loading phases: 210 mg Na per day.	Only Na loading performed intravenously which introduces variability. Low Na phase was extreme: Only 210 mg per day.	Protocol 1: Mean arterial blood pressure in hypertensives fell and rose with Na (116 to 104 to 110 mm Hg). Mean arterial blood pressure in normotensives remained stable throughout (84 to 83 to 81 mm Hg). Protocol 2: Mean arterial blood pressure in hypertensives and some normotensives rose and fell with Na (107 to 111 to 98 mm Hg and 83 to 87 to 82 mm Hg). Separate analysis of subjects who participated in both protocols suggested that sequence was not important.	Short study Low Na diet was extreme Population differed between two protocols. Means of administering Na differed between different phases.
Hypertension Prevention Trial Research Group (1990). (Ref. 124) ..	Intervention trial (parallel design) 3 years. Na determined by timed, overnight, urine collection blood pressure determined as average of 2 measurements Individuals received dietary counseling (once a week for 10 weeks, then every other week for 4 weeks, then every other month for the duration of the study).	841 subjects (DBP: 78–89 mm Hg) (no antihypertensive medication or evidence of cardiovascular disease) (65.3% male) (82.2% white) (Average age: 38.6 years) Randomized into 5 groups.	4 intervention groups and a control. 5 groups: 1) Reduce calories, 2) Reduce Na, 3) Reduce calories and Na, 4) Reduce Na and increase K, 5) Control.	N/A.....	Group goal of 50% reduction in average dietary NA Individual goal of less than 1610 mg/d.	Multipliers used to estimate 24-hour Na from timed, overnight, urine collections. All groups, including the control, had reductions in Na excretion and in blood pressure during follow-up. Largest sustained reduction in Na occurred on the group encouraged to reduce both NA and calories. Intervention populations blood pressure levels were lower than those of the control population.	Na reduction statistically significant at 6 months ($p = 0.002$) and marginal at 3 years ($p = 0.053$) blood pressure reductions generally below those of control population, but changes were not statistically significant.	Authors note that maintaining dietary changes in free-living populations is difficult.

TABLE 2.—SODIUM/HYPERTENSION STUDIES—Continued

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
Koopman (1990). (Ref. 76)	Clinical intervention trial. Dietary counseling and feedback, follow-up from 3 to 18 months Na determined monthly by 24-hr excretion blood pressure determined monthly. Participants asked to return for evaluation at 18 months.	28 mild to moderate hypertensives (average initial SBP: 144.5 mm Hg, average initial DBP: 95.4 mm Hg).	Dietary counseling and feedback monthly. Dietary counseling and Na and blood pressure measurements ended at 12 months.	N/A	Low Na diets encouraged.	7 subjects dropped out (4 for high DBP, 2 for suspected angina, and 1 for stroke). During 1st 3 months of study, participants had been divided into an intervention and a control group. Control group participants received dietary counseling from 3 to 12 months. Intervention group participants received counseling from 0 to 12 months.	Average Na decrease of 510 mg per 24 hrs ($p<0.05$). Average decrease in SBP of 3.7 mm Hg ($p<0.05$). Average decrease in DBP of 4.0 mm Hg ($p<0.01$). Na and blood pressure decrease during first 6 months then leveled off at lower values.	Small study. No untreated control group followed throughout.
Lasaridis (1989). (Ref. 55)	Clinical intervention trial. 2 days: adaptation period. 5 days: low Na diet. 5 days: high Na diet. Blood pressure (supine and standing) determined 3 times per day. Na determined by 24-hr urine excretion.	18 hypertensive patients. (10 males, 8 females). (Average age: 47.3 years). (Age range: 30–64 years of age).	N/A	N/A	Controlled low Na diet: 1150 mg Na per day. Controlled high Na diet: 4600 mg Na per day.	Blood pressure determined by automated device. Patients on high Na diet had an average increase in body weight of 1.3 kg ($p<0.01$). "Responders" (8 patients with a change in mean supine blood pressure >8 mm Hg). Low-renin patients (6 patients with plasma renin activity <3 ng/ml per hr during Na deprivation). "Responders" were virtually all low-renin patients.	Average Na rose from 1180 to 4440 mg Na per day ($p<0.001$). Average supine blood pressure rose 6.7 mm Hg (from 102.7 to 109.4 mm Hg) ($p<0.001$). Average standing blood pressure rose 5.0 mm Hg (from 107.6 to 112.6 mm Hg) (not significant).	Small study Not clear if patients were receiving or had received antihypertensive medication. Low-renin patients appeared to respond better to changes in Na.
Luft (1990). (Ref. 79)	Placebo controlled crossover trial. Phase 1: 4 days: low Na diet. 7 days: low Na diet plus mineral water with NaCl or NaHCO3. Phase 2: 4 days: low Na diet. 7 days; low Na diet plus mineral water with NaHCO3 or NaCl. All urine collected. Phase 1 and Phase 2 conducted a month apart.	10 mildly hypertensive subjects (blood pressure >140/90 mm Hg) and 10 normotensive subjects (blood pressure <140/90 mm Hg) (10 male, 10 female) (10 black, 10 white) (Average age: 36 years) Randomized into two groups.	NaHCO3 Phase: 3 liters per day of mineral water containing NaHCO3 (26.2 mmol/l Na, 33.03 mmol/l HCO3, and 4.23 mmol/l (Cl). NaCl Phase: 3 liters per day of mineral water containing NaCl (26.2 mmol/l Na and 36.07 mmol/l Cl).	1810 mg Na per day.	Controlled low Na diet containing 1380 mg Na per day. All foods prepared and eaten at research center. Same food eaten for each meal every day during both phases of study.	Blood pressure determined by automated device. NaHCO3 mineral water contained 12.69 mmol Cl per day. Base diet contained 60 mmol Cl per day. NaCl increased calcium excretion whereas NaHCO3 did not.	NaCl intake period: Blood pressure did not change in hypertensive or normotensive subjects. NaCHO3 intake period: SBP decreased by 5 mm Hg in hypertensive subjects ($p<0.05$). SBP did not change in normotensive subjects. DPB did not change in hypertensive or normotensive subjects.	Small sample size NaCl and NaCHO3 may differ in their effects on blood pressure.

TABLE 2.—SODIUM/HYPERTENSION STUDIES—Continued

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
MacGregor (1989). (Ref. 122)	Double blind, placebo controlled, crossover trial. 2 months: observation, 4 weeks: low Na diet phase, 1 month: 1st diet phase, 1 month: 2nd diet phase, 1 month: 3rd diet phase, 12 months: follow up. Diet phases included total daily diets of 1150, 2300, and 4600 mg Na. Blood pressure determined as average of 5 measurements. Na determined as average of 2 24-hr urine collections.	20 subjects with mild hypertension (DBP: 90–110). (11 men, 9 women). (15 whites, 5 blacks). (Average age: 57 years). (Age range: 42–72 years).	1150 mg Na phase: 16 placebo tablets per day. 2300 mg Na phase: 7 (10 mmol) slow release NaCl tablets plus 9 placebo tablets per day. 4600 mg Na phase: 16 (10 mmol) slow release NaCl tablets per day.	1150 mg Na phase: 0 mg Na per day. 2300 mg Na phase: 1610 mg Na per day. 4600 mg Na phase: 3680 mg Na per day.	Low Na diet (690–1150 mg Na per day) monitored by 24-hr urine collection and dietary counseling.	Excluded patients with renal failure, ischaemic heart disease, cerebrovascular disease, and those taking oral contraceptives or other drugs. Weight increased as Na increased, but change was not significant. 16 to 20 (1 moved, 3 medicated) controlled blood pressure by salt restriction alone for the year following the study (Na of 1420 mg per 24 hr, SBP of 142 mm Hg, DBP of 87 mm Hg).	Na in 3 phases was 1130, 2480, and 4370 mg per 24-hr. SBP in 3 phases was 147, 155, and 163 mm Hg. DBP in 3 phases was 91, 95, and 100 mm Hg. Average change in blood pressure from lowest to highest Na intake was 16 mm Hg SBP and 9 mm Hg DBP ($p<0.001$).	Blood pressure differences were not affected by the order in which the Na intake was altered. Necessary to have some salt-free products (i.e. salt-free bread) in order to reach the dietary Na intake of 690–1150 mg Na per day.
Mascioli (1991). (Ref. 109)	Double blind, placebo controlled, crossover trial. Phase 1: 4 weeks: NaCl or placebo capsules. Phase 2: 4 weeks: placebo or NaCl capsules. Phase 1 preceded by 2 weeks of testing and 8 weeks of dietary counseling to achieve low Na diet. 2 week washout period (placebo capsules) between phases. Low Na diet continued throughout.	48 normotensive subjects. (SBP<150 mm Hg, DBP: 80–89). (47 white, 1 black). (79% male)..... (Average age: 52 years) Randomized into two groups.	Intervention phase: 6 (16 meq) NaCl capsules per day Control Phase: 6 placebo capsules per day.	2210 mg Na per day.	Low Na diet (<805 mg Na per timed overnight, 8-hr urine excretion assessed prior to Phase 1 by 5 consecutive overnight urine collections below 805 mg Na).	23% of initial participants excluded for high urine NA levels. 2 subjects dropped out. Blood pressure measured every 2 weeks (twice at each visit) 8-hr urine measured at beginning of Phase 1 and at end of each phase. Subjects lost weight and blood pressure dropping during diet only phase.	Average SBP 3.6 mm Hg higher during NaCl treatment period as compared with placebo period ($p<0.001$). Average DBP 2.3 mm Hg higher during NaCl treatment period as compared with placebo period ($p<0.005$). 65% and 69% of participants experienced an increase of SBP and DBP, respectively, when on NaCl capsules as compared with placebo capsules.	Sound methodology Estimated 3–6 mm Hg increase in SBP and 2–4 mm Hg increase in DBP associated with 2300 mg increase in Na intake.

TABLE 2.—SODIUM/HYPERTENSION STUDIES—Continued

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
Mtabaji (1990). (Ref. 80).....	Clinical intervention trial. 3 days: control phase. 7 days: diet phase. One group on Low Na diet other on normal diet plus Na as consomme soup. Blood pressure determined daily. Na determined by 24-hr Na excretion.	30 normotensive Tanzanian black male subjects Randomized into two groups.	High Na group: 250mmol NaCl per day as consomme soup.	High Na group: 5750 mg Na.	Control phase: Diet of unspecified Na content. Low Na group: 1150 mg Na per day. High Na group: Normal diet of unspecified Na content.	Blood pressure determined by automated device. Ages of participants not specified.	Significant difference between two groups within 4–5 days ($p<0.001$). Low Na group: Na of 1200 mg per day. Mean arterial blood pressure fell from 87 to 81 mm Hg. High Na group: Na of 7750 mg per day. Mean arterial blood pressure rose from 86 to 89 mm Hg.	Control diet and normal diet of unknown Na content. Single population: High Na diet phase was excessively high in NA (7750 mg per day).
Smith (1988). (Ref. 41).....	Cross sectional study. Part of Scottish heart health study. Data collected from 1984–1986. Na intake determined by single 24-hr urine collection. Blood pressure determined by average of 2 measurements.	7354 subjects from 22 districts in Scotland (3754 males, 3600 females). (Age range: 40–59 years) Subjects chosen at random.	N/A.....	N/A.....	Normal diets.....	Single Na measurement does not assess previous or habitual Na intake habits. 74% response rate, 17.5% excluded (generally for failure to provide urine). 1.6% excluded due to antihypertensive medication. Confounding factors: age, body mass index, pulse rate, alcohol consumption, potassium intake.	Weak, positive correlation between Na and blood pressure in both sexes. Na correlation with SBP 0.025 for males and 0.055 for females. Na correlation with DBP 0.026 for males and 0.052 for females. Na not independently significant after multivariant analysis.	Large study population. Single community (Scotland).

TABLE 2.—SODIUM/HYPERTENSION STUDIES—Continued

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
Staessen (1988). (Ref. 42)	Cross sectional intervention trial. 5 years (1979–1985). Mass media campaign to avoid salt directed mainly at women in one town. Control town was observed. Urinary NA excretion and blood pressure determined at beginning and end of intervention.	Intervention town of 12,000 and control town of 9,000 Belgian inhabitants. 2211 subjects examined (5 and 10% random sample at baseline in control and intervention town, respectively; doubled at follow-up). Previous participants excluded from follow-up. Data from 1697 subjects analyzed. (777 males, 733 females) with and without 187 subjects on antihypertensive medication.	Intervention town (IT): Leaflets sent to all homes, posters displayed, radio and newspaper ads run. Active support from Town Council, local health officials and practitioners, and insurance organizations. Local bakers and restaurants asked to prepare low-salt foods. Women's clubs, health education courses, and children's homework targeted. Control town (CT): Salt not mentioned as a health hazard.	N/A	Normal diets	Data from teens excluded (464 subjects). Data excluded if urine volume or creatinine excretion outside limits (50 subjects). Blood pressure determined as average of 10 measurements collected at 2 home visits 2–5 weeks apart. Na determined by 24-hr urine extraction. Baseline and follow-up data taken on different subjects.	The trends in Na, SBP, and DBP in men and women were similar between the two towns except for Na in women which was significantly lower in the IT than in the CT. Na changes ranged from +180 mg in females in CT to −410 mg in females in IT. SBP changes ranged from −4.4 mm Hg in males in CT to −9.1 mm Hg in females in IT. DBP changes ranged from +1.8 mm Hg in males in CT to −2.8 in females in IT.	Large range of variation in results affects interpretation (eg.: change in Na in females in control town was + 180 ±210 mg). No independent assessment of information available to subjects in control town between 1979 and 1985 regarding Na and health hazards. Inconclusive.
Stamler, R. (1989). (Ref. 70)	Intervention trial 5 years. Intervention subjects: Extensive dietary and lifestyle counseling varying from 2 visits per week initially to 4 visits per year. Control subjects: 2 visits per year Blood pressure measured 2 times per year Na from urinary excretion measured 1 time per year.	201 hypertension prone subjects (high normal DBP: 85–89 mm Hg) or (high normal DBP: 80–84 plus 10–49% overweight) and/or (rapid resting pulse rate >80 beats per min). Randomized into two groups (102 intervention subjects and 99 control subjects).	Intervention goals: 1) Reduce daily NA intake, 2) Reduce alcohol intake, 3) Reduce overweight, 4) Increase moderate physical activity.	N/A	Goal of <1800 mg Na per day. 13% of intervention subjects achieved Na intervention goal. Average Na intake reduced by 24% in intervention group (drop from 3980 mg/day to 3040 mg/day) vs 6% in control group (drop from 4300 mg/day to 4060 mg/day)($p<0.001$).	Multiple interventions. Blood pressure measure at worksite and at office and worksite measurements used for comparison. 24-hr NA estimated from timed, 8-hr Na excretion and multipliers. Statistically significant changes in 3 of 4 interventions: NA intake, alcohol intake, and weight reduction. Statistically significant relationship with blood pressure in one of 4 interventions: weight reduction.	19% of control subjects and 9% of intervention subjects developed hypertension (DBP >90 mm Hg or medication). SBP: Reduction of 2.6 mm Hg (from 122.5 to 119.8 mm Hg) in intervention group vs 1.3 mm Hg in control group (from 122.7 to 121.5 mm Hg). DBP: Reduction of 1.3 mm Hg (from 82.5 to 81.2) in intervention group vs 0.1 in control group (from 82.6 to 82.5 mm Hg). Relationship between Na and blood pressure not independently significant.	Appropriate statistical tools used. Low dropout rate: 87% participating at least 4 years.

TABLE 2.—SODIUM/HYPERTENSION STUDIES—Continued

Reference	Study design and duration	Subjects	Treatment or intervention	Intake of test material	Base diet	Other factors	Results	Assessment and comments
Takemori (1989). (Ref. 71)	Cross sectional study Na intake determined by spot urine. Blood pressure determined by single measurement. Data collected in 1985.	7,441 Japanese females from 88 urban and 81 rural municipalities including all prefectures in Japan. (3933 urban subjects, 3508 rural subjects). (3 age groups between 40 and 69 years of age).	N/A	N/A	Normal diet averaging 3720 mg Na per day.	History of being hypertensive or on antihypertensive medicine not considered. Confounding factors: age, height, weight, potassium.	Increase of 2300 mg Na per day related to increase of 4.5 mm Hg SBP (urban: 4.1 mm Hg, rural: 4.9 mm Hg) and an increase of 1.6 mm Hg DBP (urban: 1.2 mm Hg, rural: 2.0 mm Hg).	Spot urine and predictive equations used to estimate 24-hr Na adds to uncertainty of results. Single population.
Trials of Hypertension Prevention (TOHP) Collaborative Research Group (Abstract) (1991). (Ref. 123)	Clinical intervention trial. Investigation of 7 nonpharmacological interventions in persons with high normal blood pressure. Checked at 6, 12, and 18 months into study.	2182 subjects with high normal blood pressure. (DBP: 80–89 mm Hg). (Age range: 30–54 years) randomized to 1 of 8 groups.	7 interventions (3 lifestyle changes for 18 months, 4 nutrition supplements for 6 months) and 1 control). 1) weight loss and exercise, 2) NA restriction, 3) stress management, 4) calcium supplementation, 5) magnesium supplementation, 6) potassium supplementation, 7) fish oil supplementation, 8) control.	None	None	None	39% reduction in Na at 18 months. SBP 1.5 mm Hg lower at 18 months ($p=0.05$). DBP 0.8 mm Hg lower at 18 months ($p=0.07$).	Authors suggest that weight loss and Na restriction are the most promising nonpharmacological interventions for hypertension control.

TABLE 3.—SODIUM/HYPERTENSION META-ANALYSES

Reference	Study design and duration	Subjects	Other factors	Results	Assessment and comments
Cutler (1991) (Ref. 94)	Meta-analysis of 23 randomized clinical trials published before January 1990. Analyzed separately for hypertensives, normotensives, and total subjects.	Total: 23 trials with 1536 subjects. Data for hypertensive and normotensive subjects analyzed separately and together.	Excluded trials with confounded designs. Excluded 2 trials for Na intake outside the usual ranges for Na. Magnitude of results was reduced slightly when inverse variance weights were included. All results statistically significant except for DBP in normotensives after including an adjustment for inverse variance weights.	Hypertensives: Net reductions in Na ranged from 1290 to 2410 mg. Average pooled reductions in blood pressure were 4.9 mm Hg (SBP) and 2.6 mm Hg (DBP). Normotensives: Net reductions in Na ranged from 370 to 3910 mg. Average pooled reductions in blood pressure were 1.7 mm Hg (SBP) and 1.0 mm Hg (DBP). Totals: Net reductions in Na ranged from 370 to 3910 mg. Average pooled reductions in blood pressure were 2.9 mm Hg (SBP) and 1.6 mm Hg (DBP).	Studies used a variety of different methodologies (unstandardized). Selected only randomized trials which eliminates selection bias. Authors indicate there is evidence for a dose-response relationship between Na and blood pressure.
Elliott (1991) (Ref. 97)	Meta-analysis of 14 observational studies in 16 populations. Only studies that provided 24-hr urine and blood pressure data and published quantitative regression or correlation estimates.	12,503 subjects (7099 men, 6136 women)	Excluded studies that compared hypertensives with normotensives. Excluded studies that just reported significance without quantification. Data corrected for within-individual variability in Na ("reliability") using INTERSALT estimate. 2 studies of only men, 1 study of only women, 2 studies of only combined data for women and men combined.	Reduction of 2300 mg Na related to reduction in SBP of 3.7 mm Hg and in DBP of 2.0 mm Hg. Regression coefficients somewhat larger in women than in men.	Variety of study designs (unstandardized methodology).
Frost (1991) (Ref. 100)	Meta-analysis of 14 published studies of blood pressure and Na intake. 24 hour Na excretion. One blood pressure measurement. 24 hour intake of NA adjusted due to common underestimation.	12,773 people from Europe, Asia, and the United States.	None	2 mm Hg decrease in blood pressure for every 100 mmol decrease in 24 hour NA intake. Weak effect within populations—reduced Na intake reduced blood pressure slightly. Unclear how study controlled for confounding factors. One of three studies suggesting that Na reduction reduces SBP and the risk of mortality due to hypertension.	Variety of study methodologies (unstandardized).
Law (1991a) (Ref. 106)	Meta-analysis: 12 developing 12 developed communities Cross sectional studies	47,000 people from 24 communities.	Developed versus developing communities. Confounders: Potassium, alcohol, and body mass linked to Na. These varied between, but not within, the two groups. Blacks excluded from study because blood pressure in these communities were higher than for communities with similar Na intake. The effect was measured in both developing and developed communities.	Blood pressure varied according to intake. The change in blood pressure was relative to the age and existing blood pressure. It appeared that there was not a lower Na threshold below which no effect was measured.	Variety of study methodologies (unstandardized).
Law (1991b) (Ref. 107)	Meta-analysis of 78 published studies that recorded the effect of salt restriction on blood pressure. Variable duration: Researchers subdivided the data from studies that recruited both subjects with high blood pressure and subjects with normal blood pressure to allow separate assessment of the effect of salt restriction for each category.	Not stated	Some of the trials were not randomized which could introduce bias.	Salt reduction lowered blood pressure in persons with high blood pressure and in those with normal blood pressure. In people aged 50–59, a reduction in daily Na intake of 50 mmol (about 3 g salt), after a few weeks, lowered SBP by an average of 5 mm Hg and by 7 mm Hg in those with high blood pressure DBP was lowered by about half this amount.	Variety of study methodologies (unstandardized). Authors suggest that the effect of moderate dietary salt reduction on mortality from stroke and ischemic heart disease would be substantial. Authors concluded that the effect of salt reduction on blood pressure was larger than previously reported. Unclear exactly how authors controlled for confounding factors in this study.

Regulatory Impact Analysis of the Proposed Rules to Amend the Food Labeling Regulations

AGENCY: Food and Drug Administration, HHS.

ACTION: Regulatory impact analysis statement.

SUMMARY: The Food and Drug Administration (FDA) is publishing herein the regulatory impact analysis (RIA) that it has prepared under Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96-354) on the costs and benefits of the food labeling regulations that FDA is currently proposing to amend. FDA is issuing these proposals (published elsewhere in this issue of the **Federal Register**) in response to the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) and as part of the Secretary of Health and Human Services' (the Secretary's) food labeling reform initiative. The agency has prepared this comprehensive RIA document for these proposals because, when taken together, they constitute a major rule.

DATES: Written comments by February 25, 1992.

ADDRESSES: Submit written comments to the Dockets Management Branch (HFA-305), Food and Drug Administration, Rm. 1-23, 12420 Parklawn Dr., Rockville, MD 20857. Comments should be identified with the docket number found in brackets in the heading of this document.

FOR FURTHER INFORMATION CONTACT: Richard A. Williams, Jr., Center for Food Safety and Applied Nutrition (HFF-303), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-485-0271.

SUPPLEMENTARY INFORMATION: FDA is publishing herein its RIA of the proposed rules to amend the food labeling regulations. This document analyzes both the costs and the benefits, including the impact on small businesses, of FDA's proposals (published elsewhere in this issue of the **Federal Register**) to reform the food label in response to the 1990 amendments and the Secretary's food labeling initiative. This analysis was prepared by the Economics Section of the Office of Compliance in FDA's Center for Food Safety and Applied Nutrition (CFSAN).

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96-354), FDA has developed one comprehensive RIA that presents the costs and benefits of all of the food labeling proposals taken together. FDA requests comments on the RIA.

I. Introduction

The 1990 amendments amend the Federal Food, Drug, and Cosmetic Act (the act) to expand the coverage of nutrition labeling to all food products (except meat and poultry), produce more ingredient labeling, regulate health claims, and standardize nutrient content claim definitions and serving sizes. The 1990 amendments require that the nutrition information on both the food label and on eating establishment menus be readily understandable by the public. These changes to the food label are the most comprehensive changes to be proposed in 53 years. FDA has proposed implementing regulations for the 1990 amendments and estimated the costs and benefits of the proposed changes and regulatory options within the act. However, even before the 1990 amendments were enacted FDA believed that the food label could be improved and was engaged in proposing a series of similar regulations.

In order to evaluate the need for Federal intervention, FDA examined the market for food label information and found that less than the optimal amount of nutrition information was being produced because consumers cannot, independently, determine the nutritional quality of food, thus leading to insufficient incentives for manufacturers to reveal the nutrient content of their products or produce nutritious food. FDA undertook two studies to determine the costs and benefits of these proposed regulations, by engaging a contractor, Research Triangle Institute (RTI). These studies were done over a period of 3 years under the direction of the Economics Section of CFSAN.

A. Costs of the 1990 Amendments

The cost study consisted of both interviews with food manufacturers and a mailed survey. The result was a generic model which can be applied to any regulation mandating a label change. Categories of costs include administrative, analytical, printing, inventory, and reformulation. Administrative costs are management costs which are often high because of the prominence of the food label as an advertising tool for packaged foods. Analytical costs are costs of testing products for nutrient composition to comply with labeling provisions. Printing costs are the costs of printing new labels which may be either glue-on labels or the food package itself. These costs may include redesign costs where extensive labeling changes are undertaken. In the model, estimates of printing costs take into account normal firm relabeling.

Inventory costs are the costs of disposal of existing labels where firms have inventories that outlast the compliance period, i.e., the period of time between issuance of a final rule and its effective date. Inventories of labels, both glue-on labels and packages, range from only a few months to well over 10 years in the food industry. The last cost category reformulation includes the costs of reformulating products and introducing new ones in response to labeling regulations and market testing those products. No estimate of these costs is given because they depend on marketing decisions and are impossible to predict. Moreover, they do not result directly from these proposed rules. Regardless, FDA expects a substantial benefit to be derived from such reformulations, which are likely to make foods more nutritious. In all cost categories, except administrative costs, the costs of relabeling products produced and labeled in foreign countries cannot be separated from those produced and labeled domestically. Thus, administrative costs considered are domestic costs only, and printing, inventory, and analytical costs are considered multinational.

FDA estimates that about 17,000 domestic food manufacturers and 257,000 labels will be affected by the regulations promulgated in response to the 1990 amendments. In addition, approximately 96,000 food service firms might be required to alter their menus if they are not in compliance with health claims or descriptors regulations. The majority of the costs will occur in the first year. Recurring costs are assumed to continue 20 years into the future and are discounted back to the present at a rate of 5 percent.

The individual regulations may be divided into the following separable categories: (1) Mandatory ingredient labeling for standardized foods and certified colors; (2) "voluntary" (see section III.E. of this document) labeling

of raw fruit, vegetables, and fish; and (3) all other labeling regulations including mandatory nutrition labeling. The first category, mandatory ingredient labeling for standardized foods and certified colors, is separable from the other actions because it will take effect almost 2 years prior to mandatory nutrition labeling. Costs for these provisions, as proposed, are $128 million.

Voluntary labeling of raw fruit, vegetables, and fish is separable from all other provisions of the 1990 amendments because it affects supermarkets, not food manufacturers. Costs have been estimated to be between $117 to $155 million for this provision.

All other labeling regulations will become effective at the same time including percent juice labeling, mandatory nutrition labeling, nutrient content claims definition, health claim labeling, format changes and others. These costs to food manufacturers are estimated to be as high as $1.3 billion, depending on the compliance period chosen.

In addition, there could be costs to some restaurants and other food service establishments to reprint menus not in conformance with nutrient content and/or health claim regulations. For those firms wishing to continue use of these statements following publication of the final rules for these regulations, there could be additional costs of analytical testing and, possibly, nutrition information printing. These costs have been preliminarily estimated to be $116 million.

Total costs of the 1990 amendments, excluding the voluntary supermarket labeling, are approximately $1.5 billion. If the agency opted to allow an additional 6 months or an additional year to the compliance period provided for by the statute, total costs would decrease to $.8 billion and $.6 billion, respectively.

B. Benefits of the 1990 Amendments

The benefits of the 1990 amendments include decreased rates of cancer, coronary heart disease (CHD), osteoporosis, obesity, hypertension, and allergic reactions to food. As consumers are given more informative labeling in a better format, uncertainty over the ingredient and nutrient content of the foods they now eat will decrease and some consumers will select more nutritious, healthier foods. Also, with creation of consistent metrics and definitions such as standardized serving sizes and adjectival nutrient content claim definitions by which consumers can judge the nutritional aspects of foods, manufacturers will compete to reformulate their products into healthier foods. Thus, even those consumers who may be unaware of the diet/health revolution may inadvertently eat a better diet.

The model chosen to estimate these benefits focused on the two largest health problems, cancer and CHD (Ref. 24). This model involved the following three-step estimation process:

(1) Estimate changes in consumer purchase behavior and resulting changes in nutrient intakes as a result of receiving new nutrient information about foods.

(2) Estimate the changes in health states that would result from consumers' changes in nutrient intakes, particularly for reduced incidence of cancer and CHD.

(3) Estimate the value of changes in health states in terms of life-years gained, number of cases and deaths avoided and the dollar value of such benefits.

The estimate of benefits was obtained from the Special Dietary Alert program (SDA) (Ref. 1), a special program done by FDA in conjunction with Giant Food, Inc., which measures actual consumer response to new nutrition information. Reductions in the amount of cancer cases and early deaths were estimated to occur as a result of reduced total fat intake after a lag of 10 years. CHD reductions were estimated to result from lowered serum cholesterol as a result of decreases in saturated fat and cholesterol intake. Over the 20-year period the regulation is estimated to prevent about 39,100 cases of cancer and heart disease, of which, 12,900 would have resulted in death, yielding 80,900 life-years gained. The monetary value of the benefits (number of life-years saved) of this regulation is estimated to be $3.6 billion (discounted at 5 percent over a 20-year period). Valuing benefits based on the number of lives saved would raise this value to $21 billion (discounted at 5 percent over a 20-year period).

To put these estimates into perspective, the maximum health changes resulting from "perfect" diets were estimated by comparing the average nutrient intake of men and women in the U.S. with Daily Reference Values (DRVs). These numbers were then adjusted to reflect only FDA regulated foods. This estimate is a measure of all potential benefits to be derived from consumers eating a healthier diet while maintaining their current consumption of meat and poultry. The results indicate that if all consumers were to adopt "perfect diets" from FDA-regulated foods, 500,000 cases of CHD and cancer resulting in 213,000 premature deaths would be avoided over the next 20 years.

FDA has determined that these proposed rules are major rules as defined by Executive Order 12291, and have significant effect on a substantial number of small entities as defined by the Regulatory Flexibility Act.

II. Purpose of the Regulatory Impact Analysis

The purpose of this RIA is to determine the economic effects of the proposed rules to amend the food labeling regulations in 21 CFR parts 5, 100, 101, 105, and 130. This analysis is intended to satisfy the requirements of an RIA as specified in Executive Order 12291 as well as the requirements for a Regulatory Flexibility Analysis as specified in the Regulatory Flexibility Act.

Guidance for determining whether these actions constitute a "major" impact under Executive Order 12291 includes the criteria in Section 1b of the Executive Order itself, and informal supplementary guidance provided by The Department of Health and Human Services's (DHHS) Handbook on Developing Low Burden and Low Cost Regulatory Proposals, dated February 1984. Guidance for determining whether this action creates "a significant impact on a substantial number of small entities" includes definitions in section 601 of the Regulatory Flexibility Act (Pub. L. 96–354) and informal supplementary guidance provided by the DHHS Handbook.

FDA requests comments concerning the various considerations and conclusions it used in determining the quantitative or qualitative costs and benefits for this proposed regulation.

III. Description of the Proposed Action

FDA is responding to the 1990 amendments to amend the act. The 1990 amendments provide FDA specific authority to issue regulations concerning food labeling. The rulemaking actions analyzed in this document are as follows:

A. Mandatory Status of Nutrition Labeling and Nutrient Content Revision

These actions require nutrition labeling on most foods that are meaningful sources of nutrients and revise the list of required nutrients and the conditions for listing nutrients in nutrition labeling. The 1990 amendments specify that nutrition labeling shall include information on:

(1) The total number of calories derived from any source, and the number of calories derived from fat;

(2) The amount of total fat, saturated fat (i.e., saturated fatty acids), cholesterol, total carbohydrate, complex carbohydrate, sugars, dietary fiber, total protein, and sodium; and,

(3) Any vitamin, mineral, or other nutrient required to be placed on the label before October 1, 1990.

In response to a Citizen's petition, the agency is also proposing to allow the use of the protein digestibility-corrected amino acid scoring method for foods intended for persons of all ages, except infants.

FDA is further proposing that, when a food contains insignificant amounts of more than one-half the required nutrients, a simplified format shall be used.

B. Revision of Reference Daily Intakes and Daily Reference Values

This action updates the U.S. Recommended Daily Allowances (RDA's) used in food labeling and replaces the term U.S. RDA with Reference Daily Intake (RDI). The agency is also proposing a separate set of DRV's for fat, fatty acids, cholesterol, carbohydrate, fiber, sodium and potassium, substances for which RDAs have not been set.

C. Declaration of Ingredients

FDA is proposing the following changes in regard to the label declaration of ingredients:

(1) Require label declaration of certified food colors;

(2) Require label declaration of all ingredients in standardized foods;

(3) Require that when more than one sweetener is used in a product, all sweeteners be declared together by common or usual names in descending order of predominance by weight, in parentheses in the list of ingredients, following the collective term "sweeteners;"

(4) Require the declaration of all protein hydrolysates by their common or usual name, including the identification of the food source;

(5) Require identification of a caseinate as a milk derivative in foods labeled as nondairy foods; and,

(6) Require that labels bear an explanatory statement that the list of ingredients is in descending order of predominance.

FDA is also proposing two voluntary provisions including:

(1) Provide a uniform format for voluntary declaration of percentage ingredient information, and

(2) Permit inclusion of the food source in the names of several of the sweeteners prescribed by food standards.

The agency is also responding to comments by advising sellers that wax or resin coatings on fresh fruit must be labeled with the specific wax (currently required) name or the proposed collective names. This language emphasizes regulatory enforcement of an existing requirement. FDA advises that the information must be placed in a conspicuous place where the produce is displayed in bulk but retailers are allowed sufficient flexibility to choose the specific location. Producers or distributors are required to supply the information to retailers through labeling accompanying the produce. In the case of resins, a statement of function must appear in the labeling. The 1990 amendments exempt produce sold in small open containers.

D. Percent Juice Labeling

The agency is proposing to:

(1) Require declaration of the total percentage of juice and the percentage of each represented juice on both single and multiple juice beverages;

(2) Require percentages of juice to be expressed in one percent increments. For multiple juice beverages, if manufacturers declare one or more individual juices or picture them on the vignette, or represent their presence in any other way, the percent of these individual juices will have to be identified. If major modifications (i.e., changes in the color, taste, or other organoleptic properties) have been made to a juice to the extent that the original juice is not recognizable, or if its nutrient profile has been diminished, then the juice may not count toward the total percent of juice. FDA believes it is appropriate to include juices with minor modifications such as acid-reduced orange juice. If the beverage contains no fruit or vegetable juices, and either fruit or vegetables are pictured on the vignette or the labeling, or the color or flavor of the product implies that a juice is present, then it must be labeled as containing zero percent juice;

(3) Describe where the percentage label statement must be on the container; and

(4) Provide directions on how to name various classes of juices and juice beverages, e.g., "diluted grape juice beverage."

E. Labeling of Raw Fruit, Vegetables, and Fish

The 1990 amendments require that FDA:

(1) Develop guidelines for food retailers for the "voluntary" nutrition labeling of raw agricultural commodities and raw fish;

(2) Identify the 20 varieties of raw fruit, vegetables, and fish most frequently consumed to which the guidelines apply; and

(3) Define substantial compliance with respect to adherence by food retailers to the guidelines.

F. Serving Sizes

This action will ensure that serving sizes are standardized to reflect the amount of the food customarily consumed. In this action FDA will establish mandatory declarations of serving sizes to be used on the nutrition panel which will reflect either the customary amount consumed, e.g., 6 ounces (oz) or the customary unit of consumption, e.g., a slice of bread.

G. Nutrient Content Claims

This action establishes definitions for and proper conditions for use of terms describing cholesterol content, fat content, sodium content, calorie content, and other nutrient content claims on packaged food labels and on food service establishment menus and menu boards. Also, FDA will establish a procedure for handling petitions for inclusion of a claim in a brand name through informal rulemaking.

H. Nutrition Label Format

The 1990 amendments state that implementing regulations "shall require the required information to be conveyed to the public in a manner which enables the public to readily observe and comprehend such information and to understand its relative significance in the context of a total daily diet." FDA will propose to revise the nutrition label format.

I. Health Claims

FDA is proposing general procedures that cover the regulation of health claims on both packaged food labels and on food service establishment menus and menu boards. The 1990 amendments require that the agency issue regulations in 10 diet/health topic areas determining whether health claims may be made in conjunction with specific food components. In addition, FDA will establish a procedure for handling petitions for new claims.

IV. Market Failure

The *Regulatory Program of the United States Government—1990 to 1991* (Ref. 40) notes that agencies must evaluate the existence of a "market failure" which will be addressed by Government action. According to Leftwich, "A market failure is said to occur when either quantity or quality of a good

produced in an unregulated market differs from what is purported to be the social optimum" (Ref. 2). Because there is no objective standard by which the performance of markets may be compared, it may be more instructive to present a comparison of how freely operating markets respond to various interventions and contrast the respective levels of transactions costs. This "comparative institution approach" (Ref. 3) utilizes a positive analysis to predict the outcomes of different institutional sets of property rights (Ref. 4). In this approach, both the unattenuated market and administrative institutions have strengths and weaknesses. Markets are assumed to be low cost transmitters of information to coordinate economic activity between producers and consumers, thereby lowering "identification" costs. The strength of administrative solutions lies in taking advantage of scale economies to enforce difficult or ambiguous property rights.

When "a large number of people are involved and * * * the costs of handling the problem through the market or the firm are high, governmental administrative regulation should lead to an improvement in economic efficiency" (Ref. 5). That is, "* * * a particular good or service may be available at a fixed cost which, if borne by all of those who benefit from it, would cost no more than each beneficiary would be willing to pay. However, if the beneficiaries are so numerous that coordination among them is expensive, either in terms of locating and exacting payment from class members or in terms of measuring relative benefits and, hence, relative charges to each, then potential buyers may forego, wholly or in part, an otherwise desirable good or service" (Ref. 6). In short, when the transaction costs of effecting a purchase or sale are high, the market may produce costly misallocations and redistributions of social resources. When this occurs, government intervention may produce a superior outcome to the market outcome (Ref. 7).

A more probable market failure in food labeling, however, is the problem of asymmetric information that characterizes a market for "lemons" (Ref. 8). Since consumers cannot judge nutritional quality for themselves, manufacturers are unable to charge a premium for high "quality foods" so that only the foods with the lowest nutritional value are produced and marketed.

V. Economic Impact Analysis

A. Costs of the Proposed Actions

This section describes and estimates the costs of the 1990 amendments. The discussion of costs includes a discussion of sources of data, industries affected, and quantitative estimates of the various requirements. Although most costs are a direct result of specific provisions of the legislation and may not be changed, FDA has cost altering options with respect to the time firms have to comply with mandatory nutrition labeling, whether or not eating and drinking establishments are affected by the regulation, and other, lesser options.

1. Sources of Information

The anticipated cost to manufacturers covered by these regulations was estimated using a compliance cost model for food labeling created for FDA by RTI (Ref. 9). RTI conducted their study of food labeling costs in two phases. In the first phase, RTI discussed actual and hypothetical labeling policies with 30 firms of various sizes and four-digit standard industrial classifications (SICs).

Firms were encouraged to estimate the effort (resource use) and, when possible, the cost to complete different compliance activities. From the information gained in the first phase, RTI was able to produce a model of the cost of food labeling. The first phase also produced information on administrative activities.

In the second phase of the project, RTI and FDA surveyed over 350 firms to collect more printing and label inventory data. The sampling frame defined each target population as all firms within a given industry. Within each target population, the sample was stratified to reflect proportional allocation among four firm size categories: Small (less than (<) 10 employees), medium (10 to 99 employees), large (greater than (>) 99 employees), and unknown size. Firms were strongly encouraged to respond to the survey, but participation was voluntary. RTI used the survey data to update and improve the parameter estimates for the compliance cost model developed during the interview phase of the project.

The source for the estimate of the number of food processing firms is Dun and Bradstreet's Electronic Yellow Pages, which is a comprehensive data base of U.S. businesses. Food manufacturers were identified using the SIC on a four-digit level. These firms were further categorized to exclude those producing only foods regulated by the U.S. Department of Agriculture (USDA) to estimate the number of firms producing food products subject to FDA regulations. Precautions were taken in order to avoid double counting. FDA found there were some problems using this data base, such as a lack of frequent updates. However, the alternative, which is Census data, counts establishments rather than firms. Also, very small firms are not included in the Census. Therefore, FDA found the Dun and Bradstreet data base to be the better choice.

The estimate of the number of products (77,000) was derived from A.C. Nielsen sales data obtained from sampling 21,000 grocery stores with annual sales of more than $4 million each. These stores account for approximately 80 percent of the sales of packaged foods. This estimate of total food products was refined in order to include only those food products affected by FDA regulations (USDA-regulated foods were removed from the estimate). This estimate includes both domestic and foreign products for sale on U.S. grocery shelves. Although food product labels are required to list either the address of the distributor or manufacturer of the food, it is impossible to determine the location (foreign or domestic) of the manufacturer who will bear the four costs (administrative, printing, inventory, and analytical), or some portion of them. The estimate of the number of food labels (defined as stock keeping units (SKUs)) (257,000) was also derived using the data from the A.C. Nielsen data base. This estimate also includes both domestic and foreign labels for sale on U.S. grocery shelves. A separate label is applied to each brand of food in a specific size which may be further divided by flavor, color, etc. Products are also differentiated by distinct recipes and manufacturers. In other words, if a manufacturer produces a strawberry jelly and a grape jelly, he produces two products. If the jellies are each sold in two sizes (32 oz and 16 oz jars), the manufacturer has four distinct labels SKUs. In order to estimate SKUs, it was necessary to estimate the number of both branded and private labels. The latter was accomplished by estimating the relationship between the number of private brand labels and sales of private labeled products.

2. Costs of Compliance

The costs of a labeling regulation are those associated with: (1) Administrative activities, (2) analytical testing, (3) label printing, (4) label inventory disposal, and (5) reformulation (including market testing).

These costs depend on the attributes of the regulation itself and on the characteristics of the industry being regulated. Relevant attributes of the regulation include the scope of the regulation, the intricacy of the regulation, the complexity of the expected label change, and the length of the compliance period. The characteristics of the particular industry that affect the magnitude of the costs include:

(1) Firm size
(2) Label type
(3) Printing process(es)
(4) Normal label redesign frequency
(5) Average label inventory
(6) Average label order and its cost
(7) Number of products

a. *Scope of the regulation.* All food processing industries will be affected in whole or in part by these actions. Table 1, which follows, indicates which industries are affected by the various actions.

An internal review of labeling of standardized foods using the Food Packaging and Labeling Survey (FLAPS) (Ref. 15), showed that in all likelihood, all standardized foods already contain full ingredient labeling. Therefore, for cost estimation purposes, only those products which contain artificial colors will be affected by the ingredient labeling requirements (effective in November, 1991). However, cheese (SIC 2022), ice cream (SIC 2024), and milk (SIC 2026) are exempt from labeling colors.

TABLE 1.—INDUSTRIES AFFECTED BY LABELING REGULATIONS

SIC	Industry name	(Phase I regulations)			(Phase II regulations)
		Standard foods, ingredients, and colors labeling	Percent juice labeling	Raw fruit, vegetables, and fish labeling	Mandatory nutrition labeling, format, nutrient content claims
2021	Creamery butter				X
2022	Cheese, natural and processed				X
2023	Dry, condensed and evaporated milk products.	X			X
2024	Ice cream and frozen desserts				X
2026	Fluid milk				X
2032	Canned specialties				X
2033	Canned fruits and vegetables	X	X		X
2034	Dehydrated fruits, vegetables, and soups	X			X
2035	Pickles, sauces, and salad dressings	X			X
2037	Frozen fruits and vegetables	X	X		X
2038	Frozen specialties	X			X
2041	Flour and other grain mill products	X			X
2043	Cereal and breakfast foods	X			X
2044	Milled rice and byproducts				X
2045	Flour mixes and refrigerated doughs	X			X
2046	Wet corn milling				X
2051	Bread, cake, and related products	X			X
2052	Cookies and crackers	X			X
2053	Frozen bakery products except bread	X			X
2061	Sugar cane mill products and byproducts				X
2062	Refined cane sugar and byproducts				X
2063	Beet sugar				X
2064	Candy and other confectionery products	X			X
2066	Chocolate and cocoa products				X
2067	Chewing gum	X			X
2068	Nuts and seeds				X
2075	Soybean oil mills				X
2079	Edible fats and oils, nec [1]	X			X
2083	Malt and malt byproducts				X
2086	Bottled and canned soft drinks	X	X		X
2087	Flavoring extracts and syrups	X			X

2099	Food preparations, nec [1] dietary supplements grocery stores.	X		X	X

[1] Not elsewhere classified.

All products which purport to contain fruit or vegetable juices are affected by the percentage juice labeling requirements.

The 1990 amendments specifically exempt certain products from nutrition labeling but not from health claim regulations:

(1) Foods that contain insignificant amounts of all the nutrients and food components required within nutrition labeling (insignificant is defined as that amount which allows a declaration of zero in nutrition labeling);

(2) Foods sold by businesses having annual gross sales of not more than $500,000 or annual gross sales of food of not more than $50,000;

(3) Foods served in restaurants or similar food service establishments and foods that are principally processed and prepared in a retail establishment and are ready for consumption; (FDA may choose to require nutrition labeling with a nutrient content or health claim.)

(4) Foods sold by grocery stores that are offered for sale from self-service salad bars and deli or bakery counters; (FDA may choose to require nutrition labeling with a health claim.)

(5) Foods in small packages (must provide nutrition labeling at point-of-purchase);

(6) Medical foods;

(7) Infant formula;

(8) Foods shipped in bulk form; and

(9) Foods supplied for institutional food service use only.

The 1990 amendments specifically exclude restaurant foods from the requirement for nutrition labeling. However, the agency believes it has the authority to issue regulations requiring restaurants that choose to make health claims or nutrient content claims to adhere to the requirements for such claims, including nutrition labeling. In 1989, there were a total of 536,796 commercial food service establishments (CFEs), as illustrated in table 2 (Refs. 10 and 11). In addition, there were 172,131 institutional and 1,256 military food service establishments. Institutional establishments include employee food service, school and hospital cafeterias, penal institutions, nursing homes, and transportation food service. However, only institutional establishments which actually sell food are potentially affected such that prisons, for example, would not be covered.

TABLE 2.—FOOD SERVICE ESTABLISHMENTS

Eating places	331,926
Drinking places	37,227
Lodging places	27,199
Retail hosts	108,397
Food contractors	15,739
Recreation and sports food service	12, 414
Other (vending/catering/mobile)	5,894
Total commercial food service	536,796
Institutional feeding	172,131
Military feeding	1,256
Total food service establishments	710,183

Nutrient content and health claims regulations applicable to food service establishments would apply to all forms of labeling in those establishments: Menus, signs, and posters. FDA believes that posters and other types of menu boards in restaurants are generally changed frequently, at least every 6 months. FDA requests input as to the validity of this assumption. Assuming menu boards are changed frequently, the cost of changing these items will not be considered in this assessment. This analysis will therefore consider only the cost of the currently proposed regulations on changing printed menus and lighted menu boards using preprinted plastic strips to indicate menu items, and the cost of any implied nutrition testing. Approximately 294,051- CFEs may be assumed to have some sort of commercially printed menu, as indicated in table 3. Not all categories of food service establishments can be assumed to have written menus as many establishments may use menu boards and signs. Although there are no data on the number of food service establishments using written menus, a rough estimate of this number may be generated by listing only those establishments in categories for which it seems reasonable to assume written menus. This has been done in table 2. The number of establishments in each category are taken from "The Food Service Industry: 1989 in Review (Ref. 10). Note that the agency assumes only 36 percent of the total number of limited menu restaurants in 1989 have written menus. This corresponds to the portion of all limited menu restaurants falling into one of the following three categories in 1987:

(1) Table, booth, counter seat with waiter/waitress service;

(2) Take out or drive through; and

(3) Other (Ref. 11).

TABLE 3.—ESTIMATED TOTAL NUMBER OF NONINSTITUTIONAL AND NONMILITARY COMMERCIAL FOOD SERVICE ESTABLISHMENTS HAVING PRINTED MENUS

Restaurants and lunchrooms	160,859
Limited menu restaurants (incl. fast food)	52,658
Bars and taverns	37,727
Lodging places	27,199
Store restaurants	16,108
Total	294,051

One of the most significant developments in the restaurant industry has been the shift toward healthier options on the menu. For example, in 1990, the National Restaurant Association (NRA) found 34 percent of the menus submitted to its annual menu contest have "light and healthy" menu sections, compared to only 12 percent in 1985 (Ref. 12). Similarly, in a survey of its members, the NRA found that 55 percent of respondents "featured or promoted items because of their specific health or nutrition benefit (Ref. 13)." Any nutrient content claim or health claim not in compliance would require a change in the printed menu. If it is conservatively assumed that none are in compliance, then 55 percent is an approximation of the proportion of the total number of menus likely to be affected by the current proposal. There are several potential problems encountered with using this survey to estimate the current use of health claims and nutrient content claims. First, the survey was not designed to be a representative sample of the entire industry, only of the membership of the NRA. Secondly, this approach will not reveal where a single respondent may have had such nutrient content claims or health claims on more than one menu, i.e., on both lunch and dinner menus. Thirdly, it will not reveal which CFEs currently using such terms will be in compliance with regulations governing those claims and nutrient content claims.

Finally, there is no way to determine from the survey which restaurants currently using nutrient content claims and health claims will continue to do so following publication of the final rules. Firms may discontinue use of these terms both because many recipes and types of nutrient content claims will not qualify under the proposed guidelines, and because of the additional costs of analytical testing. Those firms choosing not to continue to use these terms will have to change their menus, but may not have to undergo nutrient analysis.

Under the preceding assumptions, an estimated 161,728 CFEs will be affected potentially. Assuming, further, that 30 percent of the CFEs under consideration would normally change their printed menus within the time allowed by the regulation, 113,210 CFEs will have to change their menus involuntarily as a result of the current regulations. FDA recognizes that the above assumptions are speculative and FDA requests information regarding these issues.

To generate a more accurate assessment of the number of firms affected, FDA requests information concerning the proportion of firms using health claims or nutrient content claims with respect to nonmeat and nonpoultry dishes, the number of menus affected, and the number of such firms that are already in compliance with FDA regulations governing those claims and nutrient content claims.

In addition, a certain proportion of those CFEs not using printed menus, but using menu boards, will also be affected. Since these menu boards typically do not contain as much information as

printed menus, the agency assumes that a smaller proportion of these establishments use nutrient content and/or health claims. As an example, FDA assumes 5 percent of CFEs using menu boards (i.e., not assumed to have printed menus), or 12,137, use health claims or nutrient content claims.

Although nutrition labeling for fresh produce and fish is "voluntary," it will become mandatory if FDA determines that "substantial compliance" has not been met. Because FDA has determined that it is not necessary that all firms comply for substantial compliance to be achieved, some "free riding" may occur. That is, firms may attempt to rely on their competitors to label, which would lead to a low overall compliance rate. However, because: (1) The grocery industry may wish to avoid mandatory regulations, (2) there is a low minimum compliance cost per firm, and (3) firms may have to label to be competitive, full compliance may occur.

b. *Effective dates.* The 1990 amendments require that final regulations become effective 6 months after the date of promulgation of all final regulations. If no final regulations have issued by November 8, 1992, the proposals are statutorily mandated to be considered final rules on November 8, 1992, with an effective date of May 8, 1993. The 1990 amendments allow the Secretary to delay the effective date of some of the provisions for up to 1 year if he finds that compliance with the new provisions of the act would cause undue economic hardship.

FDA is proposing to make certain of the provisions of the ingredient labeling regulations effective on the same date as the nutrition labeling rule. The exception to this is the provisions for the listing of all ingredients in standardized food and the listing of all FDA-certified colors which must take effect November 8, 1991 (Pub. L. 102–108). Under the provisions of Pub. L. 102–108, those firms whose inventory is depleted between July 1, 1991 and May 8, 1993 are required to revise such labels for their products consistent with the proposal in the **Federal Register** of June 21, 1991 (56 FR 28592). Such firms will bear administrative costs and redesign costs to include color and standardized food ingredient information. There will be no analytical costs, inventory costs or printing costs outside of redesign costs as this additional printing is not prompted by requirements of this regulation.

Table 4 shows the separable proposed regulations for enactment of the 1990 amendments.

TABLE 4.—EFFECTIVE DATES FOR THE 1990 AMENDMENTS

Proposed rule	Optional effective dates		
	[1] 1	[1] 2	[1] 3
Declaration of ingredient/color labeling	[2] 11/91		
Percent juice labeling	5/93	11/93	5/94
Raw fruit, vegetables, and fish	11/91		
Cholesterol free and percent fat labeling	5/93	11/93	5/94
Mandatory status of nutrition labeling and nutrient content revision	5/93	11/93	5/94
Nutrient content claims	5/93	11/93	5/94
Cholesterol, fat, and fatty acid labeling	5/93	11/93	5/94
Lite butter	5/93	11/93	5/94
Nutrient content claim and a standardized term	5/93	11/93	5/94
Serving sizes	5/93	11/93	5/94
Petitions requesting exemption from Federal preemption	[2] 11/91		
Health claims general requirements	5/93	11/93	5/94
State enforcement provisions of 1990 Amendments	11/92		

[1] The 1990 amendments allow the Commissioner of Food and Drugs to delay the effective date beyond Option 1 if there is a "substantial economic burden" on industry to comply with any of these regulations. The effective date in Option 1 is prescribed by the 1990 Amendments and the two alternates are 6 month extensions of that date.

[2] The date when manufacturers affected by these regulations and who reprint their labels must be in compliance with the regulation.

FDA notes, however, that in section 10(a)(3)(B) of the 1990 amendments, Congress provides that if the Secretary of Health and Human Services (the Secretary), and by delegation FDA, finds that requiring compliance with section 403(q) of the act, on mandatory nutrition labeling, or with section 403(r)(2) of the act, on nutrient content claims, 6 months after publication of the final rules in the **Federal Register** would cause undue economic hardship, the Secretary may delay the application of these sections for no more than 1 year. In light of the agency's tentative findings in its regulatory impact analysis that compliance with the 1990 amendments by May 8, 1993, will cost $1.5 billion, and that 6 month and 1 year extensions of that compliance date will result in savings that arguably outweigh the lost benefits, FDA believes that the question of whether it can and should provide for an extension of the effective date of sections 403(q) and (r)(2) of the act is squarely raised.

FDA has carefully studied the language of section 10(a)(3)(B) of the 1990 amendments and sees a number of questions that need to be addressed. The first question is the meaning of "undue economic hardship." FDA recognizes that the costs of compliance with the new law are high, but those costs derive in large measure from the great number of labels and firms involved. The agency questions whether the costs reflected in the aggregate number represent "undue economic hardship." Therefore, FDA requests comments on how it should assess "undue economic hardship." Should it assess this question on a firm-by-firm basis, as was provided in the bill that passed the House Committee on Energy and Commerce (H. Rept. 101–538, 101st Cong., 2d sess., 24 (1990)), an industry-by-industry basis, or should it assess this question on an aggregate basis? If the agency should take the latter approach, comments should provide evidence that would permit the agency to make a determination that there is "undue economic hardship" for most companies. FDA also points out that assessing hardship on a firm-by-firm basis would likely be extremely burdensome because of the likely number of requests.

FDA will consider the question of the meaning and appropriate application of section 10(a)(3)(B) of the 1990 amendments as soon as possible after the comment period closes. The agency intends to publish a notice in advance of any final rule announcing how it will implement this section to assist firms in planning how they will comply with the act. The early publication of this notice is to assist firms in avoiding any unnecessary expenses that could be incurred by trying to comply with a compliance date that may cause "undue economic hardship."

c. *Administrative costs.* The administrative costs associated with a labeling regulation are the dollar value of the incremental administrative effort expended in order to comply with a regulation. The administrative activities which are anticipated to be undertaken in response to a change in a regulation include: Identifying the underlying policy of the regulation, interpreting that policy relative to the firm's products, determining the scope and coverage related to product labels, establishing a corporate position, formulating a method for compliance, and managing the compliance method.

The magnitude of administrative costs to a representative firm is a function of several variables including the scope and intricacy of the regulation (positive relationship), the number of distinct products, and the length of the compliance period associated with the regulation (inverse relationship). Minor regulations are those which have little if any effect on product composition or

marketability. The compliance method for these regulations is usually straightforward and no testing or reformulation is involved. Conversely, intricate regulations are those that lead to analytical testing and, possibly, product reformulations or discontinuations. Intricate regulations require more administrative effort than minor ones.

In addition, longer compliance periods decrease administrative costs because firm executives might delegate downward decisions that are less immediate. According to RTI, many firms estimate that administrative effort would be twice as high for a 6-month compliance period as for a 12-month period. Similarly, a 24-month compliance period would reduce administrative effort due to a simplified coordination of the compliance process.

Administrative costs also vary with firm size in that larger firms often have a more comprehensive approval process for label changes than smaller firms. In addition, administrative costs have a largely variable component for labeling decisions such that these costs are part variable and part fixed. Larger firms also tend to have more products and more labels or stockkeeping units (SKU's), so that there are more label changes (per dollar of sales) that the larger firms must coordinate. For this RIA, administrative costs associated with intricate regulations are estimated at $9,000 for small/medium firms (less than 100 employees) and $68,450 for large firms. For less intricate regulations, the costs are estimated at $850 for small/medium firms and $6,300 for large firms. These costs have been estimated for domestic firms only as FDA has no information on administrative costs for foreign firms. Total administrative costs also only reflect costs to domestic firms.

Administrative costs for the one-time relabeling changes for listing ingredients on labels for standardized foods and artificial colors on labels for all foods containing them will affect 12,800 firms (of which 1,145 are large (based on Dunn and Bradstreet study)) who will incur administrative costs of $16 million. These will be administrative costs of overseeing redesign only as these costs will only occur to firms who are reprinting labels in the interim period.

Administrative costs for all of the 1990 amendments (mandatory nutrition labeling, format changes, etc.) are assumed to be those associated with intricate regulations for the 8,900 medium and large firms (based on Dunn and Bradstreet study). These administrative activities are valued at $152 million.

FDA estimates that manufacturers of dietary supplements will incur administrative costs of $850 per firm. Costs for these firms will be $138,000.

These costs are additive because firms affected by the ingredient provisions (who reprint labels in the interim period) must also relabel to comply with mandatory nutrition labeling. In sum, these provisions are estimated to impose one-time costs of $168 million.

d. *Analytical testing.* Analytical tests are typically performed by technical personnel employed by firms or at independent laboratories. These costs consist of tests to determine nutrient and food component quantities required by various labeling provisions.

FDA assumes all firms affected by the percent juice labeling requirements will perform analytical testing to determine the °Brix level, which is the level of soluble solids in fruit juice, in their products. This assumption is conservative in that some firms may already perform °Brix analyses and no testing would be needed for 100 percent juice products. In addition, firms that produce more than one-juice mixed juice beverage would only need to test each individual juice once. FDA has no information as to the extent of either of these conditions.

The current total cost of analytical tests to determine the °Brix level in juices and juice products is $17 per product. This figure is based on the pricing schedules of five independent testing laboratories. It is assumed that three analyses are required for the initial data base. Therefore, the cost of analytical testing for percent juice labeling is $51 for each of approximately 3,800 products (A. C. Nielson study) for a total cost of $196,000. The recurring analytical costs are $65,000 every 5 years. Assuming recurring analytical costs continue 20 years into the future, total discounted analytical costs are $343,000 (5 percent discount rate). If discounted at 10 percent, these costs would be $287,000. These costs are also discounted at 10 percent for comparison purposes as, later in the document, the benefits estimate is discounted at 10 percent.

In determining the extent to which firms will incur analytical testing costs as a result of mandatory nutritional labeling, it is important to estimate the number of products/labels which currently contain nutrition information on their labels. The costs of compliance for those firms who have never voluntarily obtained nutrition information will be higher than for those firms who are currently performing some or all of the newly required tests.

Based on the most recent information from the 1988 FLAPS, nutrition-labeled products account for an estimated 61 percent of the annual sales of processed, packaged foods. However, this estimate refers not to the percentage of products labeled, but rather to the percentage of the dollar value of packaged foods.

Unfortunately, there is no good estimate of the number of products or labels which currently contain nutrition information on the label although it is certainly less than 61 percent. This is because the FLAPS sample is made up of an equal number of market leader (defined as the top three brands in the survey) and nonleader brands. Although market leader brands may account for 75 percent of sales, they are also approximately 1.5 times as likely to provide nutrition labeling than nonleaders. In addition, there are many more nonleaders in the market than market leaders. Consequently, the percentage of brands currently containing nutrition information on the label is estimated to be 40 percent (Ref. 15).

Some firms that do not currently provide nutrition labeling are nonetheless aware of the nutritional characteristics of their food products with the help of prior nutritional testing. Consequently, less than 60 percent of the products may incur the full cost associated with the analysis. FDA has no direct information to estimate the percentage of firms which may be conducting nutrition testing without labeling this information. However, FDA estimates that 20 percent of all firms are already conducting the newly required nutrient analyses, perhaps in anticipation of the 1990 amendments. For this 20 percent of all firms, no additional testing will be required. Although tests already performed are a sunk or historical cost, their inclusion provides an historical account of the costs of these proposed regulations. A cost that has already been incurred is said to be a sunk or historical cost and is not an economic cost because no choice is associated with it. In addition, 32 percent of the firms (40 percent currently labeling × 80 percent not performing all tests) are performing the currently required tests and will, therefore, incur only the incremental analytical testing costs. The remaining 48 percent are assumed not to be currently testing their products and will, therefore, incur the total cost of a nutritional analysis. All tests include both domestic and foreign firms who sell products in U.S. supermarkets.

The total cost of nutrient testing to ensure compliance with current

regulations is approximately $354 per sample. The cost of that portion of the current tests which will no longer be required (testing for thiamin, riboflavin, and niacin) is $135 per sample. In addition to current requirements, firms will be required to test for cholesterol, fiber, fatty acids, and sugars. These tests currently cost $376 per sample. These figures are based on the pricing schedules of five independent testing laboratories. It is assumed that three analyses are required for the initial data base. The formula for determining initial testing costs for the firms who do not currently test their products is [(354–135+376)×3] or $1785 per product. Incremental initial costs for the firms who perform the currently prescribed testing but do not test for the newly prescribed nutrients will be $723 [(376–135)×3] per product. Total initial analytical costs for mandatory nutrition labeling are $112 million (including historical costs). Firms are assumed to retest once every 5 years on average. These costs are reduced to one-third of the original costs, or $37 million. As stated previously, it is assumed that three analyses are required for the initial data base. Only one analysis is required for subsequent testing. Assuming recurring costs continue 20 years into the future, discounted total analytical costs, again including historical costs, are $195 million (5 percent discount rate). At a 10 percent discount rate, these costs would be $163 million. These costs were calculated by adding costs of three tests in the first year and an additional test in the 5th, 10th, 15th, and 20th years, respectively.

TABLE 5.—ANALYTICAL COSTS OF MANDATORY NUTRITION LABELING

	Percent of all products	Incremental cost per product
Currently testing for all nutrients	20	[1] 0
Currently testing for only required nutrients (currently labeled)	[2] 32	$723 [(376–135)×3]
Not currently testing (not currently labeled)	[3] 48	$1785 [(354–135+376)×3]

[1] Historical cost included in total as $723.
[2] (80 percent×40 percent).
[3] (80 percent×60 percent).

FDA believes the incremental analytical testing costs for manufacturers of dietary supplements would be very small. Due to the nature of the product, FDA believes that full analytical testing is already performed on most dietary supplements. FDA requests information on this assumption.

e. *Printing.* Incremental printing costs depend on the type of printing process(es) used, the complexity of the label change, and the length of the compliance period. Because printing activities are specific to individual labels, computing incremental printing effort on a per-SKU basis is necessary.

There are three printing processes used in the food processing industry. These include lithography, flexography, and gravure. The particular process used will indicate the type of plate or cylinder which will be modified or replaced.

Often referred to as "offset," lithography is the most popular process for glue-applied label printing because of its relative advantages in quality, simplicity, and cost. Approximately 43 percent of all food labels are printed using lithography.

Flexography is acceptable for many products and applications in the food industry. However, because the screen elements on the plates are flexible, vignettes are sometimes printed with ragged, irregular patterns. It is used on approximately 43 percent of food labels.

Gravure is capable of high quality pictorial reproductions, high-color densities, and bright intensive solids because it can deposit thick ink films. However, it does not print type as sharply as lithography or flexography. Gravure is used on 14 percent of food labels.

Flexography and lithography have similar incremental printing costs although lithography is slightly more expensive on average. Gravure is a relatively costly printing process. It is not unusual for the incremental printing cost of a label printed with gravure to be three or four times the cost for the identical change when printed with lithography or flexography.

The complexity of the label change determines the level of effort for artwork (the illustrative and decorative elements of printed materials), stripping or image assembly (the assembly or positioning of negatives (or positives) on a flat prior to platemaking), and engraving (the carving, cutting, or etching into a block or surface used for printing). It also determines the number of plates or cylinders that must be modified or replaced. The most common labeling regulations require lettering changes to an area inside the information panel.

Line copy changes usually affect only one label color (printing plate), and it is unlikely that the services of a label artist will be needed. In most cases, a film assembler and an engraver modify an existing plate or produce a new one.

Despite the similarity and relative simplicity of line copy changes, firms differ in incremental printing effort. If flexography or lithography printing is used, many firms engrave new lettering onto an existing printing plate to save time and resources. Other firms order new printing plates regardless of how minor the line copy change may be. For gravure printing, every label change will result in a new cylinder since modifying gravure cylinders is not possible.

The requirements proposed for listing of ingredients on standardized foods and the listing of colors on labels will result in a relatively simple two-color label change. However, by the second effective date, the entire food label will be redesigned to incorporate all changes. Virtually all food products will be expected to carry revised ingredient labeling, nutrition information, and possibly a new nutrition label format. For those products which do not currently have this information, the current label contents will have to be rearranged in order to make room for the new panels. For those products which currently carry nutrition information, the changes required are so comprehensive that it is assumed that the entire label will be redesigned. In fact, those products affected by the regulations defining various nutrient content claim definitions will incur changes to the principal display panel (PDP) as well as to the information panel. In addition, the format chosen may also cause the PDP to be redesigned, depending on the new size of the nutrition panel.

Complex label changes are influenced by the same variables, but the level of effort required for each printing activity is higher. Any label change affecting the PDP will affect the visual appeal of a label. In such a case, an artist may be used to partially redesign the label. This would frequently affect all colors on the label, resulting in substantial artwork, photography, and engraving to complete the label change.

The length of the compliance period determines the firm's ability to combine planned label changes with mandated changes. The amount of printing costs assigned to a mandated printing change depends primarily on the length of time available to make the change. Label redesigning schedules vary from approximately 4 weeks to longer than 10 years. Most firms redesign food labels at least once every 5 years, with many redesigning branded labels at intervals of less than 1 year. Depending upon the complexity and similarity of planned

and mandated changes, a firm could significantly reduce incremental printing activities by combining both changes.

It is estimated that there are approximately 257,000 food labels currently on the market (based on A. C. Nielsen study). These labels represent both domestic and foreign products. Although products are labeled according to the country of origin, products may be imported and then labeled or exported, labeled in other countries and then reimported or other variations. Such variations make it impossible to distinguish between foreign and domestic firms in terms of bearing the cost of label printing.

Because firms will be able to combine planned and mandated changes for some labels, incremental costs will be incurred for fewer than 257,000 food labels. Using the methodology provided in the contractor's cost study, the cost of printing new labels for the mandated changes which will be effective by at least May 1993 will be $643 million. Printing costs are a function of the number of labels that must be printed, the type of process used for printing the labels, and the complexity of the mandated printing change, i.e., number of colors involved and whether or not the label must be redesigned. The printing activities in response to ingredient labeling (redesign costs only are counted) will cost $112 million.

Printing costs for dietary supplements are expected to be $250 per product. FDA estimates there are approximately 3,400 unique dietary supplement products on the market. This leads to a total printing cost for dietary supplements of $858,000. Thus, total printing costs will be $756 million.

f. *Label inventory disposal costs.* An additional cost category is the label inventory loss associated with the transition from old to new labels. The cost of label inventory loss depends on average label inventory and the length of the compliance period. The key variable in this relationship is average label supply. Label supply differs significantly across industries and firms, but a great deal of variation is sometimes present across product lines within the same firm.

There are many different types of labels, usually classified according to their construction and method of application: preprinted and direct. Preprinted labels are printed on special label paper, cut to size, and applied by machines to the container or package using special adhesives. Direct labels are printed directly on the container or package. Therefore, for certain products, such as canned soft drinks, the label which must be disposed of is actually the container.

As discussed above, the average label supply and length of the compliance period are the most important factors in determining inventory disposal costs. If allowed 2 years, for example, most label inventory will be depleted. Because firms will be able to dispose of inventory prior to making label changes, there will be no incremental inventory disposal costs as a result of the declaration of certified colors and ingredient declaration. However, additional costs of $306 million are estimated to be incurred as a result of the second phase of regulations if a 6-month compliance date must be met. Thus, total costs for inventory disposal of food labels amounts to $421 million. These costs include both domestic and foreign firms.

FDA has no information to determine inventory disposal costs for dietary supplements. We assume firms will be able to use up existing supplies within the 6-month compliance period.

g. *Reformulation.* FDA believes that firms may react to labeling regulations by reformulating existing products or introducing new products. Product reformulation occurs when a firm which must now reveal nutritional characteristics competes to provide more nutritious products for the marginal consumers who drive the market for quality. Many firms conduct market tests before distributing a reformulated or new product. These tests range from small internal taste panels to comprehensive public-use tests.

FDA does not have adequate information to determine the amount of product reformulation that may take place as a result of this regulation. Thus, while some firms may alter marketing techniques and strategies, these costs have not been quantified. Furthermore, these costs are inherently difficult to predict because they depend on future choices made by firms.

h. *Loss of trademark names.* Both the percent juice labeling document and the nutrient content claim definitions document may cause firms to alter names currently trademarked. Under Executive Order 12630, a "takings" analysis would be necessary if, in fact, this constituted a potential taking. These regulations, however, serve to reemphasize existing regulations as to how products may be named. Thus, any firm which will be forced to change the name of its product is now using terms that misbrand its products, and therefore no legal property right exists. Thus, no "takings" analysis is necessary. In the past, FDA resources have been used sparingly to enforce economic deception. Nevertheless, the (illegal) value associated with the trademark name will be lost to the firm when they change the name. Further, losses incurred by producers and consumers based on illegal names should not be counted as a societal loss (Trumbull cites Stigler, Buchanan, and others who argue that criminal gains ought not to be counted as societal gains (Ref. 16)).

i. *Costs to food service establishments.* Potential costs of the nutrient content and health claims regulations to food service establishments include costs of changing menus and menu boards, analytical testing, creating nutrition posters or handouts, and administrative costs.

i. Printed menus. To determine the costs of reprinting menus not in compliance with the proposed rules, the estimated number of CFEs having menus with health promotions and/or nutrient content claims will be allocated across different average cost of meal categories. Different menu printing costs may then be applied to the resulting figures. Within each size category, the least-cost menu printing options are considered, but it should be emphasized that these are lower-bound figures. FDA assumes that CFEs with an average cost per meal of less than $15 use a tripanel fold-out paper menu, which is estimated to cost $2.65 to print (Ref. 17). An eight-page booklet estimated to cost $4.25 to print is assumed for a CFE whose average cost per meal is between $15 and $30. For the high-scale CFE with an average cost per meal above $30, printing a single-color menu is assumed to cost $85 per 8.5x11 inch page. This analysis assumes only two pages and one color. An approximate breakdown of affected CFEs by average cost of meal category is as follows:

TABLE 6.—NUMBER OF AFFECTED COMMERCIAL FOOD ESTABLISHMENTS BY AVERAGE COST OF MEAL

Cost of meal	Affected establishments
<$15	106,242
$15 to $29.99	5,929
$30+	1,039
Total	113,210

Another factor affecting costs is the number of menus that must be printed per CFE. The number of menus that must be printed is a function of the average number of customers. Columns 1 and 2 of Table 7 present the average

distribution of seating capacity in the restaurant industry. These percentages have then been applied to the total number of restaurants in each average cost of meal category. This procedure ignores any correlation between the number of seats and the average cost of meal. That is, the same proportion of establishments with various seat sizes is ascribed to each of the average cost of meal categories. FDA is unaware of any correlation between the average meal cost and the size of an individual restaurant.

TABLE 7.—ESTIMATED NUMBER OF AFFECTED COMMERCIAL FOOD SERVICE ESTABLISHMENTS (BY CHECK SIZE AND SEATING CAPACITY) AVERAGE CHECK SIZE

Seating capacity	Percent	<$15	$15 to $29.99	$30 or more
0 to 100	0.14	14,874	830	145
101 to 150	0.21	22,311	1,245	218
150 to 199	0.18	19,124	1,067	187
200 to 400	0.33	35,060	1,957	343
>400	0.14	14,874	830	145
Total		106,242	5,929	1,039

The next step in computing menu reprinting costs is to calculate the total number of menus that must be reprinted and the cost of changing these menus for each of the three check size categories. For simplicity, the average number of seats within each range is used as a proxy for the number of menus and is multiplied by the number of restaurants within each corresponding check size. The total number of printed menus affected for CFEs is shown in table 8.

TABLE 8.—TOTAL NUMBER OF MENUS AFFECTED

Average number of seats	Average check size		
	<$15	$15 to $30	>$30
50	743,694	41,503	7,273
125	2,788,853	155,636	27,274
175	3,346,623	186,764	32,729
300	10,517,958	586,971	102,861
400	5,949,552	332,024	58,184
Total	23,346,680	1,302,898	228,320

If the average number of seats represents the number of menus that must be reprinted, the total cost of reprinting menus, less administrative cost, is $107 million, as shown below.

TABLE 9.—COSTS OF REPRINTING MENUS FOR CFES

	Average Check Size		
	< $15	$15 to $30	> $30
Total number of seats	23,346,680	1,302,898	228,320
Menu costs	× $2.65	× $4.25	× $175
Subtotals	$61,868,701	$5,537,315	$39,956,044
Total	[1] $107		

[1] Million.

ii. Menu boards. In addition to those CFEs having printed menus, a certain number of CFEs using menu boards are likely to undergo compliance costs as a result of the current proposal. As stated previously, the cost of changing menu boards utilizing separate letters that may be easily affixed or removed will be considered negligible. Thus, only those menu boards using preprinted plastic strips that must be professionally manufactured will be considered. However, FDA requests information on any other sort of menu board or printed menu that may be affected but has not been considered.

Unfortunately, no data are currently available on the percentage of CFEs having this type of menu board, or on the number of items on these boards containing nutrient content claims or health claims. However, a rough estimate of the number of items affected may be possible through the use of reasonable assumptions.

FDA believes the CFEs most likely to have menu boards with either health claims or nutrient content claims are frozen specialty shops such as frozen yogurt shops, some of whose business revolves around the ostensible nutrition advantages of their product.

The assumptions to be made on the number of menu strips affected may be broken down into three parts: (1) The number of establishments in various categories likely to have menu boards with preprinted plastic strips and thus potentially affected; (2) the number of establishments having this type of menu board now using health claims, and (3)

the number of menu strips that must be changed per affected menu board.

With respect to the first issue, the agency assumes that 50 percent of frozen food specialty shops (frozen yogurt and ice cream establishments), and 50 percent of all fast food establishments (including those that have previously been identified as having printed menus), use menu boards with preprinted plastic strips. In addition, as an example, the agency assumes that 10 percent of all other CFEs not previously considered to use printed menus, use this type of menu board.

Next, the agency assumes that 50 percent of the potentially affected menu boards used by frozen food specialty shops will contain either health claims or nutrient content claims. In addition, the agency assumes that 5 percent of all other potentially affected menu boards will have health claims or nutrient content claims. Finally, it will be assumed that an average of two strips must be replaced per affected menu board. Using the previous assumptions as an example, the number of affected menu boards would be as shown in table 10.

TABLE 10.—ESTIMATED NUMBER OF MENU BOARDS AFFECTED, BY TYPE OF ESTABLISHMENT

Limited menu (fast food)	3,657
Commercial cafeterias	37
Ice cream vendors, etc.	3,049
Miscellaneous food service	143
Food contractors	79
Retail hosts	451
Recreation and sports	62
Total	7,478

The cost of printing menu board item strips ranges from about $6 to $18 for a small number of strips (about 1 to 10) and from about $1.50 to $4 for a very large number of strips (500) (Ref. 18). Since the cost depends heavily on the number of identical strips printed at one time, an accurate assessment of these costs would entail knowledge of the number of independent and franchise establishments. As a preliminary estimate, the simple average of the range of item strip printing costs noted above, $7.40, may be used. Under the preceding assumptions, the additional cost due to changing item strips on menu boards would be about $111,000.

iii. Analytical testing costs. All firms wishing to use nutrient content claims and health claims must undergo verification testing. Analytical testing represents a cost to all firms using health claims or nutrient content claims on the menu, including those firms who would normally reprint their menus within the allotted compliance period and which were not included above. Although all firms currently using nutrient content and/or health claims will incur printing and administrative costs, not all firms will incur analytical costs. Some firms currently making claims will not continue to use them in the future, as not all menu items will meet the criteria for making claims, nor will all firms wish to bear the additional costs.

iv. Administrative costs. Firms affected by these regulations will also incur administrative costs—the dollar value of the incremental administrative effort expended in order to comply with a regulation. Although FDA has no specific information in regards to the administrative cost per restaurant, FDA estimates the relationship of administrative costs to total costs for those firms' continuing to use nutrient content and/or health claims to be approximately 15 percent of those firms' total printing and analytical costs for labeling regulations (Ref. 9). For those firms choosing to not continue the use of claims, administrative costs are estimated to be 5 percent of total printing and analytical costs applicable to those firms. Therefore, if 20 percent of firms currently making claims continue to use them, total administrative costs will be $9 million. If only 1 percent of firms currently making claims continue to use them, total administrative costs will be $6 million.

v. Total costs to food service establishments. The costs to restaurants of the regulations to define the use of nutrient content claims and health claims include the costs of changing printed menus ($107 million) and menu boards ($111,000), analytical testing costs, and administrative costs ($9 million if 20 percent of firms currently using claims continue to use them, $6 million if only 1 percent). Therefore, this speculative estimate of the total cost to restaurants of these regulations is $116 million if 20 percent of firms currently using claims continue to use them, and $113 million if only 1 percent. These costs must be considered to be preliminary estimates as many of the assumptions are speculative. Within the next year, FDA will prepare a more accurate analysis of the cost of these proposed regulations on restaurants.

j. Total costs of the mandatory regulations. The total costs of the regulations are provided in table 11:

TABLE 11.—TOTAL COSTS OF FOOD LABELING REGULATIONS [1]

[In millions of dollars]

	Phase I	Phase II	Total
Administrative costs [2]	16	161	177
Analytical costs	0	195	195
Printing costs	112	750	862
Inventory disposal costs	0	306	306
Total	128	1,412	1,540

[1] Excludes labeling of raw fruit, vegetables, and fish.

[2] Costs discounted at 5 percent.

3. Raw Fruit, Vegetables, and Fish

The costs of the action to label raw fruit, vegetables, and fish include laboratory testing; data base compilation; administrative costs; and the printing of signs, posters, handouts, etc. Because the regulation is "voluntary," it is impossible to predict the number of firms that will choose to comply although it is suspected that most, if not all, of the supermarkets will comply. If a substantial number (60 percent of all stores evaluated) are not found in compliance within 2 years, the agency will have to issue mandatory regulations. There are 31,000 chain stores and 68,000 independent grocery stores that fall under the compliance guidelines.

Compliance costs will vary depending on the particular medium chosen to convey the nutrition information. The more elaborate the labeling, the higher the cost. Brochures to be handed out, for example, would cost $4,000 to 6,000 per 100,000 brochures (Ref. 19). However, where some stores do choose to offer complicated labeling schemes as a marketing device, that would not necessarily be considered a cost of this regulation. Also, bulk orders by large chain supermarkets are expected to reduce costs substantially.

Comments have indicated to FDA that the average life of a grocery store sign is 6 months with a yearly cost of between $150 and $200 (Ref. 20). Over a 20-year period, if exactly 60 percent of supermarkets included are in compliance, the discounted cost would be between $117 ($150 per year discounted at 5 percent) and $155 million ($200 per year discounted at 5 percent).

Assuming every consumer spends the same for groceries, each store with over $2,000,000 per year in sales would have an average of 6,500 customers who would benefit from the labeling (250,000,000 consumers × 80.5 percent of sales = 203,750,000,203,750,000/31,000

supermarkets = 6,574 customers/supermarket). The independent stores, with sales under $2,000,000, would have an average of 150 customers (250,000,000 consumers × 6.6 percent of sales = 16,500,000. 16,500,000/110,000 stores = 150 consumers per store). If labeling costs $200 per store every year, labeling costs in the smaller stores would be $1.33 per consumer per year.

B. Benefits of the Proposed Option

The proposed labeling changes will benefit consumers by giving them information to refine their food choices for health or other reasons. This section contains a qualitative description of individual benefits to be derived from the implementation of each of the requirements of the 1990 amendments and a quantitative estimate of the requirements as a whole.

1. Qualitative Description of Benefits of Individual Regulations

This section will discuss the qualitative benefits of the individual regulations. The benefits of mandatory nutrition labeling will be discussed quantitatively in the next section.

a. *Labeling ingredients.* i. Sweeteners listed together. A common complaint among consumers is that the ingredient list, in descending order of predominance, may contain multiple sweeteners which appear to represent a small proportion of ingredients. For example, sugar, high fructose corn syrup, and dextrose may be used in a ready-to-eat cereal and appear to make only a marginal contribution to the product based on individual listings in the ingredient list, although, if combined, the list would show the product to have sweeteners as the primary ingredient. People wishing to control their intake of sweeteners for health reasons (e.g., diabetes, obesity) or any other reason will be better able to adjust their food choices to match their preferences as a result of this rule.

ii. Required listing of protein hydrolysates. Because of trade secrets and the complex technical names of flavors, FDA has always exempted flavors from ingredient listings (FDA is also required to exempt flavors by statute). However, that exemption has never been applied to flavor enhancers such as monosodium glutamate (MSG). This rule clarifies the status of protein hydrolysates, such as hydrolyzed vegetable protein and other protein hydrolysates, which contain small amounts of MSG and which act as both flavors and flavor enhancers, by requiring them to be listed. MSG has long been suspected of causing allergic-like reactions such as the "Chinese restaurant syndrome." This regulation will benefit those consumers who wish to avoid "protein hydrolysates."

iii. Required listing of sodium caseinates. Sodium caseinates, which are milk derivatives, are components of "nondairy" creamers. Caseinates are required to be listed by some states. However, for vegetarians, milk protein sensitive individuals, and others such as those attempting to follow religious proscriptions, it is important to know that nondairy creamers may contain a dairy product. Thus, this regulation will require that manufacturers indicate that sodium caseinates are, in fact, derived from milk.

iv. Statement that ingredients are listed in the descending order of predominance. Although FDA's regulation has been in place for a number of years, some consumers still do not understand that products are listed in the descending order of predominance. This required statement will eliminate that confusion.

v. Listing of colors. A listing of colors will provide consumers who are sensitive to them with this information as well as provide information for those who wish to avoid chemical colorants.

vi. Required listing of ingredients in standardized foods. Very little, if any, benefit will be obtained from this provision of the statute because most or all ingredients are currently listed in standardized foods.

vii. Provision of a uniform format for voluntary declaration of percentage ingredient information. Although FDA has declined to require that ingredients be listed by their percentage contribution to a product because of the potential costs of such a requirement (relative to the potential benefits), some manufacturers may choose to make such lists available in response to consumers demand. FDA is proposing a uniform format that manufacturers would use if they did choose to make such a declaration. By providing a uniform format, consumer confusion over multiple presentations would be avoided.

b. *Labeling of percent juice.* Providing consumers with the listing of percentages of fruit juice in various juice beverages will enable them to make choices consistent with their desire to obtain percentages of juice. Consumers have repeatedly asked for this information.

Other benefits include clarifying the regulation that requires consistent naming of products. Some products now marketed are mislabeled under existing regulations by failure to put the names of juices in descending order of weight predominance in the product name. A product containing 80 percent apple juice and 20 percent grape juice, for example, may not be called "grape-apple juice." This regulation restates and reenforces this regulatory principle. This regulation also clarifies the rules by which manufacturers can count a modified juice as "juice." In some cases, manufacturers have modified juice so much that only water and sugars remain.

c. *Labeling of raw fruit, vegetables, and fish.* To the extent that consumers do not now know the nutritional composition of the raw fruit, vegetables, and fish that are proposed to be included among the "top 20," some change in purchase behavior may be expected leading to a healthier diet.

d. *Standardizing serving sizes.* The 1990 amendments direct FDA to standardize serving sizes for individual foods rather than allowing each manufacturer to establish their own serving size.

In the past, manufacturers were free to select their own serving size for purposes of calculating nutrient amounts. Standardization of measurements such as weights and scales dates as far back as 3500 BC (Ref. 21). The benefits of such standardization to buyers are reduced search costs (a transactions cost of using the market) and concomitantly, an increased ability to accurately select product quality consistent with individual desires. In the case of serving sizes, manufacturers may often "game" nutritional labeling by selecting a favorable serving size. An example would be to select a smaller serving size in order to be able to claim that a product was low in fat or sodium. If similar products use different serving sizes, consumers must make the appropriate calculation to compare products. However, many consumers may not notice that different serving sizes are being used, which leads to erroneous impressions of the nutritional quality of the food.

e. *Standardizing adjectives to describe nutrient content.* Because adjectives such as low, high, etc., are a verbal qualitative description of quantitative measurement, these regulations will have similar benefits to standardization of serving sizes.

f. *Revising the nutrition label format.* Several goals will be met by this regulation. The format chosen will be one which consumers desire, find easy to use, and easily understand. Ultimately, if a new format is selected, it will cause some consumers to direct their purchase behavior towards more healthful foods.

g. *Regulating health claims.* The benefit of these proposed regulations is to provide for new information in the market in the form of health claims that are not misleading in the sense that scientific evidence supports them. Although health claims exist on the market now, they have not been legally allowed for food products. FDA has used its enforcement discretion to act against only those claims that were egregiously misleading and, in the case of restaurants, FDA has traditionally left enforcement of health claims to the states. In the past, a food which made a claim relating to preventing, curing, or treating a disease legally became a drug and was subject to drug regulations. Because the regulation of drug products is much more burdensome than that for foods, this acted as a disincentive to making such claims. These regulations will now permit these claims to be made, if precleared by FDA, so that labels for food products as well as menus and menu boards can contain health claims without being subject to drug regulations. The additional benefit to regulating the use of claims by food service establishments is to prevent consumer confusion that may occur if different rules apply to foods from different sources, i.e., packaged foods versus restaurant foods.

Because the costs to food service establishments of analytical testing and nutrition information printing are high per menu item, many food service firms might choose to remove claims from their menus. This would reduce benefits to the extent that claims that are not misleading will be removed. FDA requests information on the number of food service companies that will discontinue the use of nonmisleading health claims because of the burden imposed by the proposed regulations. FDA also requests information on the likely changes in consumer behavior, and health, if this reduction occurs. In particular, how large would the health costs be, estimated on a basis similar to that used for estimating health benefits, of increased labeling? Would any health gains from restaurants which added nutrition information to menus be as large as the losses from restaurants which stopped making only health claims at all? Would the number of truthful health claims on menus grow larger than at present if regulation did not discourage this?

As a component of labeling in general, health claims may be the primary motivating force behind consumer behavior changes (substituting toward more nutritious foods). As such, much of the benefits of the 1990 amendments will depend on how health claims are regulated. If mostly incorrect claims are prohibited, consumers will benefit from only seeing those claims that are correct. On the other hand, if claims that are likely to be true are removed, this will decrease the total benefits of the 1990 amendments as consumers will lose valuable information. However, the opportunity exists for firms to petition the agency to reinstate "true" claims. It is not clear how much consumer changes in purchases for nutrition reasons can be attributed to health claims on the front of the primary display panel versus the nutrition panel on the back of product. Ippolito and Mathios found large changes in both producer and consumer behavior due to changes in health claims (front of label), but were unable to separate out behavior changes due to the presence or absence of nutrition labeling (back of label) (Ref. 22).

2. Labeling Benefits Model

FDA looked at several possible ways of quantifying the health benefits of the 1990 amendments. The preferred method of estimating benefits is to measure actual market prices for the good in question—a willingness-to-pay model. However, the good in this case is information on the food label, which is not directly traded in the market. The market for most consumer information is for consumer durable goods, but studies on these goods do not translate well to food labeling information.

Yet another method of quantifying benefits is to use contingent valuation studies in which consumers are given structured interviews to determine their willingness to purchase a good that is not normally traded in the market. However, the more hypothetical the question, the less incentive respondents have for accurate responses (Ref. 23). FDA believes that questions relating to information which might be supplied on the food label would be too hypothetical.

Because neither willingness-to-pay nor contingent valuation studies would produce estimates of the value of new food label information, FDA decided to use an alternative market approach which projects changes in consumer purchasing patterns. It is expected that most consumers will react to the new labeling by readjusting their prior expectations about the nutritional quality of the food they are purchasing. That is, the information they learn about the amounts of saturated fat, total fat, and other nutrients will alter their food choice to discover which, among other things, ranks nutritional qualities of food. This factor then, in combination with other characteristics of food, will cause some consumers to alter their purchase behavior toward healthier food.

The model eventually chosen was created by RTI for FDA, is entitled "Estimating Health Benefits of Nutrition Label Changes" attempted to estimate health benefits through a three-step process:

(1) Estimate the changes in consumer purchase behavior and resulting changes in nutrient intakes as a result of receiving new nutrient information about foods.

(2) Estimate the changes in health states that would result from consumers' changes in nutrient intakes, particularly for reduced incidence of cancer and CHD.

(3) Estimate the value of changes in health states in terms of life-years gained, number of cases or deaths avoided, and dollar value of such benefits.

a. *Estimation of changes in consumer purchase behavior and nutrient intakes.* The magnitude of changes in nutrient intakes will depend on how consumers use the new information to alter their choice of foods. That will, in turn, depend on whether the information is important to consumers, whether it is in a format easy to understand, and how nutrition is valued relative to other food characteristics (taste, appearance, convenience, and price). The change in purchasing behavior that will ultimately lead to a change in nutrient intake is difficult to estimate. What is being projected is the change in purchasing behavior that would come as a result of new, specific, product information about which consumers already have a prior estimation.

There is no situation which exactly corresponds to this particular set of regulations which could serve as a model to estimate this change. However, FDA does have a market study of purchasing behavior change from a similar kind of situation. This study was conducted as a result of a special program done by FDA in conjunction with Giant Food, Inc. This study, entitled the SDA, used special shelf labels to call consumers' attention to various nutrient content claims of food. For example, a flag may have called attention to a product that qualified under FDA guidelines as being "low cholesterol." In addition, a guidebook was offered either free or at nominal charge.

To compute the changes in nutrient intakes for consumers that resulted during this study a four-step method was used:

(1) Identify products with a significant market share change.

(2) Estimate the number of shelf labeled and unlabeled products in each significant product category and the market share changes in each product category from unlabeled to labeled.

(3) Compute estimated changes in consumption of food from SDA categories by using the "Continuing Survey of Food Intakes by Individuals (CSFII)," and SDA results.

(4) Estimate changes in nutrient intakes from product share changes and extrapolate changes to the U.S. population (Ref. 24).

Table 12 shows the estimated nutrient changes (Ref. 24):

TABLE 12.—ESTIMATED CHANGES IN NUTRIENT INTAKES FROM THE "MARKET STUDY"

	Men	Women
Change in fat intake:		
Grams	−1.49	−0.67
Percent	−1.4	−1.1
Change in saturated fat intake:		
Grams	−0.48	−0.16
Percent	−1.3	−0.7
Change in cholesterol intake:		
Milligrams	−0.42	−0.26
Percent	−0.1	−0.1

This estimate may be construed to be a reasonable underestimate of the changes consumers are expected to make for the following reasons: (1) The SDA experiment did not cover as much of the nutritional profile as will be covered by the 1990 amendments; (2) Not all food products were covered by the SDA study; (3) Consumer awareness and concern for total and saturated fat has increased since that study was done (1988) and will likely continue to increase over the next 20 years for which benefits are estimated; (4) No reformulation was likely to take place for this small market; and (5) No estimate was made for substitutions between products (e.g., potatoes to rice).

However, there are some reasons that drive this estimate to overstate change, particula ly. First, because this information was in the form of shelf "flags" as opposed to nutrition panel information on the back of packages, consumers are more likely to be drawn to this type of labeling instead of new information on the backs of labels. However, the effect may be mitigated if firms choose to voluntarily use such : atritional "highlight" flags as an ext ensian of nutrition labeling. Also, the allowance of health claims on the front of the package may tend to simulate the effect of shelf flags.

Secondly, no net effects of dietary changes were estimated. For example, if consumers decreased their intake of milk to lower fat intake and replaced it with apple juice, this might cause a calcium deficiency and increased risk of osteoporosis. These net effects are complicated because of the extraordinarily large number of risk items associated with any food.

Thirdly, this study, when applied to the entire population over 20 years, assumes that the purchase behavior shifts observed in the SDA study will be permanent. In fact, many studies have noted transitory shifts in behavior in response to new information. Nonetheless, as diet/health links are strengthened in the next 20 years and awareness of these links increases, FDA expects that these behavioral shifts will be lasting. Finally the nutritional benefits are extrapolated to the U.S. population using a baseline for nutritional consumption that is derived from 1988 data. If in fact, there is a trend toward better diets, and to the extent that the trend continues independently of labeling changes, then this extrapolation will tend to overstate benefits.

The fact that this model neither allowed for substitutions between products nor calculated the net effect of all dietary components has been discussed as leading to either an overestimate or an underestimate of benefits. One problem that occurs now with substitutions between products is that some products as a category are almost entirely unlabeled. Putler and Frazao (1991) find that women trying to decrease their level of fat simply traded one source of fat for another between food groups (Ref. 25). The product groups that were added included the largely unlabeled dairy products and food fats and oils. Thus, labeling of all food products will mitigate this problem.

In terms of the net effects of product substitutions, FDA believes that fat, saturated fat, and cholesterol consumption changes are likely to have the largest nutritional impact on health. Furthermore, health messages will be regulated such that no claim may be made unless the food is within the boundaries for a healthy food in several aspects, i.e., saturated fat, total fat, cholesterol, and sodium. Content claims require disclosure of "negative nutrients in high amounts in close proximity to the claim and claims are prohibited if the food contains 'negative nutrients' in high amounts." It is unlikely that consumers switching to avoid consuming too much of the primary negative nutrients will encounter gross health effects from consuming different nutrients in an alternate food that would offset the benefit of reducing consumption of the primary negative nutrients. Thus, while there may be some net effects that decrease benefits as estimated, this effect is likely to be minimal. Furthermore, as consumers become more knowledgeable over time about the diet/health link, they are likely to make even more judicious diet substitutions.

b. *Estimation of changes in health states.* The next step in estimating benefits is to establish the link between changes in nutrient intakes and reductions in the probabilities of disease. Because this estimate focused solely on changes in total fat, saturated fat, and dietary cholesterol, health changes are only estimated for CHD and cancer. A computer model, developed by Dr. Warren Browner for DHHS, has been used to estimate the relationship of changes between intake of fat and dietary cholesterol and changes in cancer and CHD (Ref. 26).

This model estimates the number of cases and deaths of CHD and breast cancer, prostate cancer, and colon/rectal cancer for a 10–year period. The model is divided by age group, race, and sex and computes the expected difference in rates of death from all causes and death from CHD and the three cancers. Cancer is affected by intake of total fat and is assumed to have a 10–year latency.

For CHD, relative risks are based on logistic regression coefficients obtained from the Multiple Risk Factor Intervention Trial (MRFIT) and Framingham studies, which specify the change in CHD resulting from a change in the level of serum cholesterol (Ref. 27 and 41). Serum cholesterol changes occur as a result of changes in the intake of dietary cholesterol and saturated fat with a 2-year lag. These changes are predicted by the Hegsted equation (Ref. 28). Finally, changes in health states for both diseases were predicted for the next 20 years.

There are factors in the estimation of health effects that lead to both underestimates and overestimates.

i. Underestimates. Consumers' increased knowledge of the ingredient and nutrient composition of foods is expected to lead manufacturers, particularly those who are not now providing nutrition information and who can make low cost reformulations, to reformulate their products to make "healthier" products. An indirect benefit may thus arise as some consumers, who do not search for nutrition, inadvertently obtain healthier (reformulated) food.

Many health conditions besides CHD and cancer may be improved as a result of nutrition labeling. Examples include osteoporosis, hypertension, obesity, and diabetes.

ii. Overestimates. Use of the Hegsted equation may overestimate the possible reduction of CHD. Recent results indicate that Hegsted may have overestimated the effect of dietary cholesterol on serum cholesterol by a factor of between three or four (Ref. 29).

Many of the provisions of the ingredient labeling regulations are directed at food ingredient sensitivities such as the provision regarding caseinate in "nondairy" products.

Table 13 presents the numbers of cases and deaths from cancer and CHD that are predicted to be avoided as a result of the 1990 amendments over a 20 year period:

TABLE 13.—ESTIMATED HEALTH EFFECTS [1]

[Over 20 Years]

Cases avoided	Total annual cases	
Cancer	35,179	500,000
CHD	4,028	514,000
Deaths avoided	12,902	
Life-years gained	80,930	

[1] Uses lagtimes of 2 and 10 years for the occurrence of CHD and cancer, respectively following a diet change.

c. *Valuation of health state changes.* In order to facilitate comparison of the costs of implementing the 1990 amendments, the changes in health states (benefits) will be valued in dollars. These estimates are valued using several separate techniques which reflect different assumptions about how to estimate reductions in the probability of early deaths. Together they provide a range for the benefits of the 1990 amendments.

i. Medical care costs. Medical care costs are cash outlays for the costs of medical care (cases). The figures presented here overstate the true reduction in such costs as the costs of competing illnesses are not subtracted. That is, even though cancer or CHD may be avoided, another disease may occur such that only net savings should be reported. Because costs of average cases of all other kinds of disease are not very meaningful, gross average medical care cost savings are reported in Table 14 below (Ref 24):

TABLE 14.—AVERAGE MEDICAL CARE COSTS

[Dollars]

	Men	Women
CHD	39,838	34,241
Prostate cancer	26,880	31,782
Colon/rectum cancer	24,055	25,963

Applying these figures to the discounted (5 percent) total number of cases to be avoided over the 20-year period yields a total of $0.6 billion saved.

ii. Willingness-to-pay estimates. Avoided medical care costs undervalue the true benefits of a health care regulation because they do not include productivity losses or pain and suffering losses. A more inclusive method of valuing these losses is to estimate the amount people are willing-to-pay to reduce risk. The willingness-to-pay estimates in this section are values that consumers and workers place on risk reduction. This is different from values people place on label information, which, as discussed earlier, we were unable to directly estimate.

Willingness-to-pay studies have been done for a variety of risk situations including wage differentials between high and low risk jobs, use of seat belts to reduce risk and contingent valuation surveys. These studies reflect the fact that people routinely make decisions to accept or avoid some incremental amount of risk such as choosing between buying an automobile or a motorcycle, climbing mountains or playing softball or being a policeman versus being a secretary. These decisions may either increase or decrease risk.

The results of these studies have often been mislabeled as "value of life" estimates. These estimates represent not the value of a life, but only the value of a reduction in the statistical risk of death. Thus, it is incorrect to say that if a person values a 1 in 100 risk reduction at $10,000, then that person's life is valued at $1,000,000 ($10,000/.01). It will matter, for example, whether the marginal risk is a reduction from 100/100 to 99/100, or from 2/100 to 1/100.

Consequently, statistical willingness-to-pay figures must be understood to reflect only estimated values of marginal changes in the risk of death. It should also be pointed out that the willingness-to-pay figures used here will be applied to changes in risk (from estimated consumer behavior changes) which places additional uncertainty on these numbers.

Analysts have not reached a consensus on the best method of applying a willingness-to-pay estimate to value changes in health states. The studies mentioned above examine consumers' and workers' willingness-to-pay to reduce risk in various situations, from dying immediately of injury to dying of cancer at old age. Some analysts apply a mean figure to value the prevention of early death, others believe it is important to consider only the likely remaining number of life-years. Thus, this analysis will present both figures.

(a) *Remaining life-years approach.* The remaining life-years approach calculates a discounted value per life-year saved from mean values of willingness-to-pay to reduce the risk of death. According to analysts who favor this view, "* * * statistics about life expectancy tell us a great deal more than do stupefying tallies of death." That is, it is the length of life that is considered important, since dying of a heart attack at age 80 is posited to be of less societal concern than dying in a car accident at age 35. Use of these values, life-years saved, implies that it is worth more to society to save 60 years of life than 5 years of life.

In their study, RTI used the relatively conservative value of $1.5 million for the willingness-to-pay figure. Using the expected discounted life-years remaining from age 40, and a discount value of 5 percent, a value of $89,074 per life-year saved is derived. Combining this figure with the discounted number of life-years saved produces a benefits estimate of $3.6 billion ($7.2 billion if $3.0 million is used for the willingness-to-pay figure as is done in the next section). If benefits are discounted at 10 percent (for comparison purposes, analytical costs, which extend into the future, were also discounted at 10 percent), benefits become $3.1 billion. Benefits do not decline rapidly with discount rates as the original value of life estimate is unchanged and fewer discounted remaining years of life is offset with a higher value per year.

Benefit estimates in each year are discounted back to the time of this decision because changes in risk for CHD and cancer appear at different, distant points in time. The Office of Technology Assessment has noted that health benefits should be discounted, other things equal, because people prefer health benefits today rather than at a future time (Ref. 31). By discounting these health effects to the present time, the value that consumers place today on future benefits may be estimated. Furthermore, it is necessary to discount

benefits in order to be able to compare them to costs. The higher the discount rate used, the lower the discounted health benefits.

(b) *Mean value approach.* The mean value approach is an alternative approach which applies a mean value to all early deaths, without regard to the average remaining years of life. As this approach is based on revealed market data, it avoids a problem of the former approach in that little empirical evidence is available to estimate how consumers value changes in risk for remaining life-years.

Furthermore, some studies have estimated willingness-to-pay values for reductions in risk of death as high as $8.5 million (Ref. 32). For this approach, FDA has conservatively doubled RTIs estimate and used $3.0 million. Combining the discounted number of early deaths (7,027) with a value of $3.0 million per early death avoided produces a benefit estimate of $21 billion ($10.5 billion if $1.5 million is used for the willingness-to-pay figure as is done in the previous section).

FDA realizes the range of values presented for estimating the benefits of reducing risks to health derive from different methodologies appearing in economic literature. It is not clear whether either methodology is inherently preferable either in general or for this particular set of regulations. FDA requests comments as to either the appropriate measure to use to value reductions in health risks or whether it is appropriate to use both in a range, as has been done here.

As has been noted throughout, FDA believes that the estimate of the health gains derived from the SDA study is probably an underestimate. The two primary reasons for this belief are the fact that no reformulation took place during the SDA study and the quantification of early death benefits leave out quality of life gains from fewer cases of CHD and cancer. Each case of cancer and CHD that does not result in early death still tremendously reduces the quality of life for both the afflicted and those around them.

d. *Perfect diet study.* In addition to estimating the benefits that derived from consumers behavior change, RTI estimated the improvement in risk that would obtain if all consumers were to eat a "perfect" diet. A perfect diet is defined as the average consumer consuming over time the DRV for fat, saturated fat, and cholesterol. This estimate represents a baseline of benefits which could be derived from a diet change made by U.S. consumers, particularly affecting their rates of cancer and CHD. Although not an estimate of benefits of nutrition labeling, the estimates provided in this section help to give perspective to the benefits obtained from food labeling. Other health improvements which might take place from a diet change include diabetes, hypertension, osteoporosis, and obesity. These changes are expected to produce small health benefits relative to CHD and cancer reductions. These risk improvements will be partially obtained by FDA's current effort on the 1990 amendments and may be further obtained by FDA's or any other organization's efforts to influence the nutritional intake of the U.S. diet.

To estimate current nutrient intakes, information on U.S. consumption data was obtained from the 1987 Nationwide Food Consumption Survey (NFCS), a self-reported food intake survey conducted by USDA. Next, average DRVs were compared with actual average intakes to estimate the maximum potential change in nutrient intake. Using the same methodology to extrapolate changes in cancer and CHD that was used in the benefits estimation, it is estimated that 725,000 cases of cancer and CHD are potentially avoidable by U.S. consumers over the next 20 years.

All of the health effects avoided from consumers eating the DRVs for fat, saturated fat, and cholesterol are shown in Table 15 below:

TABLE 15.—MAXIMUM HEALTH BENEFITS FROM DIET IMPROVEMENT [1] OVER 20 YEARS

Cases of CHD and cancer avoided	725,155
Deaths avoided	308,366
Life-years gained	2,280,549

[1] Uses lagtimes of 2 and 10 years for the occurrence of CHD and cancer respectively following a diet change.

Table 15 showed the maximum possible benefits from dietary changes of all foods U.S. consumers eat. However, because the 1990 amendments point only to FDA regulated products, this maximum change is adjusted downward to exclude changes in the consumption of meat and poultry, since labels for those products are not affected. Meat and poultry represent 33 percent of total fat intake for men and 30 percent for women, and this consumption is assumed to remain unchanged.

TABLE 16.—MAXIMUM HEALTH BENEFITS FROM DIET CHANGES [1] FDA REGULATED FOODS ONLY (20 YEARS)

Cases of cancer and CHD avoided	503,448
Deaths avoided	212,596
Life-years gained	1,565,350

[1] Uses lagtimes of 2 and 10 years for the occurrence of CHD and cancer respectively following a diet change.

The numbers presented in Table 16 may seem small relative to the overall rates of cancer and CHD in this country. CHD, for example, claims over 500,000 lives per year and cancer approximately 514,000 per year (Ref. 33). However, there are many reasons that food labeling will only make a relatively small impact on these numbers. First, only small percentages of consumers change their behavior in response to new information. Secondly, deaths avoided are net after subtracting increased deaths from other causes. That is, if someone is saved from dying from CHD, he/she may die early from something else. Thirdly, there are competing causes for these diseases.

For cancer, Doll and Peto estimate that approximately 35 percent of all cancers are related to diet (Ref. 34). Yet there are many other dietary factors besides fat which cause cancer, such as natural carcinogens and carcinogens produced by storage or cooking. Similarly, CHD has multiple causes outside of fat intake, including genetic factors, smoking, and diabetes.

i. Consumer behavior. The numbers of life-years that might be gained from a better diet are large, but nutrition competes with other food attributes in determining consumer purchases. Taste, convenience, appearance, brand name, and price are all important in the decision. It is estimated that approximately 45 percent of all consumers are actually aware of labels, read them, and understand them. This estimate is calculated from various consumer studies of label awareness as shown in table 17 below.

TABLE 17.—CALCULATION OF DECISION PROBABILITIES [1] PROBABILITY

Being aware	0.76
Looking for label conditional on being aware	0.85
Reading label conditional on looking	0.92
Understanding the label conditional on having read the label	0.76
Probability of being aware, reading and understanding labels	[2] 0.45

[1] Ref. 24.
[2] Obtained by multiplying the above probabilities.

However, FDA does not assume that 45 percent of all consumers will

presently change their purchase behavior as a result of revised labels. As nutritional awareness expands, the very small percentages of nutrient changes estimated in the SDA study (around 1 percent) should increase as the number of interested consumers increases.

VI. Options Considered

Because much of the 1990 amendments is very prescriptive, FDA has very little flexibility to develop options other than with respect to the compliance period and other options as noted below. Most of the options summarized below and many others of less benefit-cost import are also discussed in the preambles to the various rules.

A. Compliance Period Options

The primary cost option alters the amount of time firms have to comply with mandatory nutrition labeling and other labeling requirements that become effective at the same time. The 1990 amendments allow the Secretary to delay the effective date for nutrition labeling, nutrient content claims, serving sizes, and health claims for up to 1 year if he finds that compliance with these provisions would cause undue economic hardship. The following discussion will provide information on the options of extending the proposed 6-month compliance period an additional 6 months (1-year compliance period) and 1 year (a compliance period of 18 months).

The first option reviewed by FDA is to extend the compliance period for mandatory nutrition labeling, etc. to 1 year (a 6-month extension). Because the length of the compliance period affects all cost categories, except analytical costs, extending the compliance period would result in significant savings. The discounted costs of this option would be $896 million (5 percent discount rate). This amounts to a savings of approximately $644 million. If discounted at 10 percent, the costs would be $872 with a savings of $668 million.

The second option available to FDA, extending the compliance period for mandatory nutrition labeling, etc. to 18 months (a 1-year extension), would result in a savings of $835 million. Total discounted costs of this option are estimated to be $705 million (5 percent discount rate).

The 1990 amendments do not allow the Secretary the option of allowing all label changes to be effective at once (i.e., delay the implementation of ingredient labeling changes until nutrition labeling regulations are final). Nor is it possible to extend the compliance period beyond 18 months.

Extending the compliance period would also reduce costs to food service establishments by allowing firms to incorporate mandated menu changes with normally scheduled changes. However, FDA has no information to quantify the reduction caused by extending the compliance period. Therefore, any comments suggesting an extension of the compliance period for these provisions should include information as to the value to restaurants and other food service establishments of extending the compliance period for these actions.

Table 18 shows the costs and benefits of each of the above options. Benefits will decline by a maximum 2.4 percent with each additional 6 months extension of time to comply, depending on how much relabeling were to take place during that period. Benefits decline only because of discounting (2.4 percent). All benefits will be obtained despite the compliance deadlines. However, because benefits today are preferred to benefits tomorrow, giving firms more time to comply with labeling will delay benefits and reduce them by the discount rate. In fact, this is only true because of the finite 20-year horizon. Benefits will decline slightly if labeling is delayed as more cases should be prevented over an infinite timespan.

TABLE 18.—ESTIMATED COSTS OF THE COMPLIANCE OPTIONS [1] (IN MILLIONS OF DOLLARS OVER 20 YEARS)

Cost type	Option 1	Option 2	Option 3
	6 months	12 months	18 months
Mandatory labeling:			
Administrative	177	93	70
Analytical	195	195	195
Printing	862	600	436
Inventory	306	8	4
Total	1,540	896	705

[1] Excludes voluntary labeling of raw fruit, vegetables, and fish.
[2] Estimate based on life-years saved. Excludes regulation of restaurant menus.

B. Options for Ingredients Labeling Provisions

FDA considered options for each of the provisions listed in the ingredients document that were not required by the 1990 amendments. Many of the options considered required more extensive labeling (e.g., source labeling for sweeteners). FDA rejected these options where there appeared to be no market failure. The most important option rejected is the elimination of "and/or" labeling for fats and oils. Because mandatory nutrition labeling allows consumers to discover the nutrients in the products they consume, the need to eliminate "and/or" labeling for fats and oils became irrelevant. Furthermore, because all mandatory ingredients in standardized foods must now be listed, FDA will consider altering current food standards policy.

C. Options for Percentage Juice Labeling Provisions

In the proposed regulation for percentage juice labeling, different options were considered to define the amount of modification that could be made to the juice counted in the percentage juice statement. If the juice has been modified in any way other than concentrating it, it may not be counted in the "contains x percent juice" statement. For example, if the color is removed from grape juice and the resulting modified juice is added to a blend of other juices, it would not be counted as adding to the total percentage juice. The more tightly "modification" is defined, the less incentive to modify the juice. It is not clear how juice products will be affected by this proposal, but other options for the definition of "modification" might allow more modification and still be counted as juice in the percentage statement.

D. Options for Voluntary Labeling of Raw Produce and Seafood

In the voluntary labeling of raw fruit, vegetables, and fish, FDA has chosen the option of allowing virtually any format to comply with this labeling. For sampling to determine compliance, one option considered was to include only large supermarkets with sales of $2 million or more (approximately 31,000 stores). This would have allowed the labeling to reach at least 80 percent of the population. By including firms under $2 million, an additional 6.6 percent of the population is reached by including an additional 68,000 stores. This increases discounted costs over a 20-year period from $54 to 99 million to $117 to 155 million. FDA has also proposed to allow less than 100 percent compliance per store and still be counted as "in substantial compliance." Because costs are relatively fixed, aggregate net benefits decrease with smaller store size and fewer consumers utilizing individual signs.

E. Options for Health Claims

For health claim regulations, FDA is required to process requests for new claims rapidly. The agency has considerable latitude concerning how well specified the supporting data for

either a new general health claim or the use of a claim in a brand name must be. The more completely specified, the lower the likelihood the potential claim will be denied because of small omissions and the higher the cost of preparing the initial request. However, total costs are likely to be higher with repeated submissions. The agency will look closely at this issue.

FDA will also have considerable latitude in choosing levels of disqualifying nutrients with the effect that, any food outside of the boundaries set for the four nutrients of concern (fat, saturated fat, sodium, and cholesterol) will be disqualified from any health claim unless firms petition the agency for an exception. The agency can also choose whether or not it will establish separate procedures and standards for claims for supplements.

The proposed regulation of health claims is different from other regulations proposed under of the 1990 amendments (except the proposed regulation of nutrient content claim definitions) in that the health claims proposal would allow firms to provide additional information where such firms believe that the additional information will benefit the marketing of their products. In determining which claims are to be allowed, the agency has some latitude. That is, the agency must establish what constitutes "significant scientific agreement among experts qualified by scientific training and experience * * *" that the claim is "valid" when determining whether or not a particular health claim will be allowed. The level of stringency that is set for what constitutes significant agreement will affect both "Type I" and "Type II" errors (A Type I error is finding something true when it is false and a Type II error is finding something false when it is true). A Type I error would occur if insufficient stringency were set and a false claim were approved. This would cause consumers to make choices toward foods that might be unwarranted substitutions. On the other hand, if the degree of stringency is set too high, a Type II error may occur in which claims that are true are not allowed. In this case, consumers may not be given valuable information to help them choose foods that contribute to better health.

These decision rules have been considered by two health claims researchers who find that a fixed consensus rule requiring a high level of consensus "assumes the costs of a Type I error (allowing a claim that proves to be false) are far greater than the costs of a Type II error (prohibiting a claim that proves to be true)" (Ref. 35). The authors point out that a consensus rule, if flexible, can be equivalent to an expected value rule.

Other authors have pointed out that a consensus is difficult to determine. An article in the *Journal of the American Medical Association* (Ref. 36) makes the point that consensus may have as much to do with "fashion" in medical theory as with objective measures of the effectiveness of the treatment. The ability to reach a consistent measure of consensus is further hampered by the uneven state of knowledge about diet and health in different areas (Ref. 37). Nevertheless, the 1990 amendments direct the agency to permit claims only if there is significant scientific agreement.

In addition, the agency has discretion with respect to how claims can be worded. If a claim may be applied to a specific brand of food, for example, manufacturers will have a stronger incentive to make such claims. If the claim must apply to a generic food group, a "free ride" problem arises. That is, firms not advertising "free ride" on the advertising of those who do. This leads to suboptimal provision of information as firms are less inclined to provide information when competitors also benefit from that information. Depending on how health claims are structured, "Sellers may also attempt to internalize the benefits of generic information by stating simply that their product possesses the desired attribute (or lacks the undesired ones) without mentioning that all competing brands do too (Ref. 38). However, such a claim may be perceived as either deceptive advertising or spurious product differentiation (Ref. 38). Whether or not a claim may be applied to a specific brand may ultimately depend on whether or not the brand has been manufactured to be different from other foods in the class or whether all foods in the class simply meet the definition for the claim. An example would be a food that has reduced fat because its ingredients are different from other foods in the class, versus a frozen vegetable where all the vegetables meet the definition for the claim. An example would be a food that has reduced fat because its ingredients are different from other foods in the class, versus a frozen vegetable where all the vegetables met the definition for the claim.

F. Options for Serving Sizes

Section 2(A)(i) of the 1990 amendments provides for packaged foods to be labeled with the serving size expressed as either a common household measure (e.g., oz.) or the common household unit of measure that expresses the serving size of the food (e.g., slice of bread). FDA has full flexibility under the law to define what these measures are and all nutrient declarations will follow from these definitions. An alternative divisor that could have been chosen (by Congress) for this purpose would be to express all foods in a single measure, e.g., 100 grams. This type of measure would be useful for making comparisons between food whereas different measures, such as common household serving sizes, must be manipulated in order to make these comparisons. The single measure approach has the additional benefit of not overloading the consumer with too much information. Nevertheless, as different foods are customarily consumed in different amounts, the single measure approach is not consistent with the 1990 amendments.

However, the option of providing information in addition to what is required remains open to manufacturers. Thus, a manufacturer who wishes to provide nutrient content information on a per ounce or per 100 gram basis in addition to the information on a standard serving size basis may do so. This type of information would help improve consumer choices across products and thus improve the total diet. Although this additional information may prove confusing to consumers, normal market forces should dictate when and where it will be useful.

G. Options for Nutrition Labeling in Food Service Establishments

FDA is not compelled by the 1990 amendments to require nutrition labeling for restaurants, even those using nutrient content claims and/or health claims. Thus, one option is to require no nutrition labeling to accompany these terms. Under this option, eating establishments might be able to use computerized data bases to determine if they are within required levels set for disqualifying nutrients. FDA has no information on whether or not such data bases would, in fact, be adequate, nor on the cost of these data bases.

An additional option is to require full nutrition labeling for all restaurants using health claims or nutrient content claims on the menu or elsewhere. Analytical tests for these nutrients, if such testing is required, would cost $1785 per menu item (three samples of the initial analysis is assumed). Firms would also bear the cost of providing nutrition information to the customer. This information could be on the menu,

a poster or sign, in a notebook, or any other possible form. FDA does not have the information to calculate these costs.

Further, FDA could opt to require an abbreviated form of nutrition information for all restaurants using health claims or nutrient content claims on the menu. Restaurants would be required, for example, to provide information on the amount of calories, total fat, saturated fat, total carbohydrates, protein, sodium, cholesterol, and the nutrient for which the claim is made (if different from the above mentioned nutrients). The cost for nutritional analyses for these nutrients is $661 per menu item (three samples for the initial analysis is assumed).

FDA also has several options regarding which firms should or should not be exempted from any requirement to provide nutrition labeling. The options available are: (1) to require nutrition information in all food service establishments with no exemptions, (2) to exempt small restaurants as defined by sales volume, or (3) to require nutrition labeling only in restaurants that are "chains." FDA has no information to calculate the costs of each of these options and requests comments with such information. Also, any proponents of these options should submit a comment including information concerning the utility of data bases and potential costs.

H. Federalism

Executive Order 12612 requires that a federalism analysis be performed whenever there is a question as to whether or not a Federal solution is mandatory for a particular problem. This analysis should include whether or not to refrain from a Federal standard and encourage States to develop their own policies to achieve program objectives, whether or not to consult State and local authorities for Federal decisionmaking, and whether or not to allow maximum flexibility for enforcement of Federal policies by States and Local governments.

The 1990 amendments direct FDA to provide regulations governing the use of health claims and nutrient content claims for all food for human consumption, including restaurants. However, in addition to regulation directly required by the amendments, FDA is proposing to require some nutrition labeling whenever a health claim or nutrient content claim is used. One option of this regulation is to remand to States or localities the decision as to whether or not nutrition labeling should be required. However, because use of health claims and nutrient content claims in restaurants is required to be regulated by the Federal Government, and because nutrition labeling is only required when triggered by the use of these terms, this action is tied to Federal law. Further, that option would have two drawbacks, however. First, travelers would have difficulty comparing menu items between different localities. Second, the costs of this regulation would be increased as chain restaurants operating in different localities would be forced to print different menus for each locality in which they operate. States and localities have the option of requiring full nutrition and/or ingredient labeling in addition to that required by FDA. If FDA regulates restaurant menus, this may raise a Federalism issue under Executive Order 12612, and the agency welcomes comment on this question.

I. Options for Other Provisions

For other actions such as definitions of nutrient content claim definitions and RDI's and DRV's, FDA will review comments on the proposals relative to definitions of Codex Alimentarius and those adopted by U.S. trading partners to attempt, where possible, to facilitate international trade.

FDA has a number of nutrition panel formats available with potentially different costs for each format. At the time this document was written, no format was chosen. However, one concern may be that the nutrition panel size of one potential format is a 240 percent increase in size over the existing format. For some products, this may cause a more extensive label redesign of the PDP than currently estimated.

VII. International Impacts

In accordance with Executive Order 12291 and other guidance received from the Office of Management and Budget (OMB), FDA has also evaluated the effects on international trade of these regulations. Guidance received from OMB requires agencies to make no explicit distinction between domestic and foreign resources when calculating costs and benefits of regulations.

FDA has evaluated the costs of this regulation to both foreign and domestic manufacturers jointly for all costs except administrative costs. It is likely that administrative costs for foreign firms will equal or exceed those of domestic firms but FDA has no information on either the number of firms or the magnitude of the costs per firm. FDA requests information on these costs.

The United States is a signatory to three agreements that provide for efforts to harmonize, inter alia, food labels bilaterally or internationally (Ref. 39). The Canada-U.S. Free Trade Agreement provides for bilateral harmonization efforts. The two international agreements are the Codex Alimentarius Commission (Codex) and the General Agreement on Tariffs and Trade (GATT). Codex, a subsidiary of the United Nations' Food and Agriculture Organization and the World Health Organization, creates advisory information on food labeling and standards for its 130 member countries with the objective of facilitating international trade while protecting consumers' health. The GATT, an agreement signed by 90 nations, provides a framework for settling trade disagreements and for conducting multilateral trade negotiations, including negotiations on nontariff trade barriers such as inconsistent labeling requirements.

The Treaty of Rome of the European Community (EC) is another international agreement with U.S. trade implications. In working toward harmonization of food labeling requirements for its 12-member countries, the EC Council has adopted a directive on nutrition labeling and is developing another directive on labeling claims.

Despite increased efforts by the United States to consider the food labeling requirements of other countries, complete harmonization of food labeling requirements is often not possible because of differing language requirements or other unique national concerns.

The primary differences between the U.S. proposed regulations and the provisions of Codex, Mexico, Canada, the EC, and other trading partners are that many of the mandatory provisions are voluntary in other countries and some of the voluntary provisions are not permitted in other countries. These regulations will cause foreign firms to have to change their English label to market their food products in the United States. Also, because definitions of some nutrients differ, additional analytical testing and compliance activities may be required; other requirements may simply provide manufacturers incentive for product reformulation. The costs for these foreign firms should be identical to those incurred by domestic firms to meet the requirements of these regulations.

Some of the key differences in FDA labeling rules compared to those of Canada, the EC, or other trading partners, which could contribute to the need for foreign firms to change English food labels or conduct additional product testing are:

(1) *The mandatory status of nutrition labeling.* Most food products FDA regulates must have nutrition labeling, whereas in Canada and the EC nutrition labeling is largely voluntary.

(2) *The expanded required content for nutrition labeling.* Nutrition labeling may be limited in Canada or the EC to the declaration of energy value, protein, carbohydrate, and fat content unless claims are made and additionally, in the case of Canada, when vitamins or minerals are added. In contrast, FDA would require the mandatory listing of a number of additional food components, including saturated fat, cholesterol, complex carbohydrate, sugars, dietary fiber, sodium, two vitamins, and two minerals.

(3) *The expanded optional content for nutrition labeling and RDI's.* Because of the proposed rule's expanded list of RDI's, FDA would permit several vitamins and minerals to be listed that would not be permitted by Canada or the EC and would also permit certain other food components to be declared relative to RDI's. The same food product marketed in the United States, Canada, and the EC might also require different percentages to be listed for some vitamin and mineral content because of differing daily intake reference values.

(4) *The definitions of food components.* FDA would define saturated fat, unsaturated fat, and sugars differently from both Canada and the EC, with implications for the formulation, analytical testing, and labeling of food products. FDA would also define carbohydrate differently from Canada but not the EC by excluding dietary fiber.

(5) *Nutrition label format and terms.* Examples of differences between the United States compared to Canada and the EC would include the permitted use of the aggregate category of unsaturated fat, the less prominent order of listing of protein, and the terms used to describe RDI's.

(6) *The mandatory declaration of nutritional content on a per serving basis expressed in household measures and parenthetically in metric units.* Canada also requires the declaration of nutritional content on a per serving basis in metric units, and permits as well the declaration in household measures (although Canada uses Imperial measures and the United States uses avoirdupois). Unlike Canada, which has established guidelines for ranges for serving sizes to use to declare nutritional content, FDA would require that single regulatory reference serving sizes serve as guidance to declare nutritional content and as the basis for labeling claims. As long as FDA's regulatory serving size falls within the range used by Canada, no trade barriers are anticipated.

Finally, dual declaration of nutritional content on a per serving basis and on a 100 gram (milliliter) basis would be permitted by FDA, Canada, and the EC, although in contrast to the United States and Canada, declaration on a 100 gram (milliliter) basis is required by the EC.

(7) *The voluntary declaration of content claims.* FDA would limit the use of terms for content claims to those defined by regulation, some of which would differ in terminology or definition from those in Canadian regulations or guidelines. The EC does not yet have a directive on content claims.

(8) *The voluntary declaration of health claims.* FDA would allow the use of certain health claims if requirements are met; in contrast, Canada is prohibited by law from allowing claims related to diet and disease on food labels. The EC does not yet have a directive on health claims.

(9) *The voluntary nutrition labeling of raw fruit, vegetables, and fish.* FDA would require an appropriate compositional data base for these products.

As before, all firms wishing to import or export into the United States must have two labels. Importing firms are faced with the same relabeling costs as U.S. firms. In addition, many are likely to have to perform two sets of analytical tests (one additional test must be performed as a result of these proposals) because of different definitions. An example is the use of different definitions for saturated fats (length of the carbon chain). It is unclear how much other countries will follow the United States' lead in changing the food label.

VIII. Summary

Total costs of these regulations have been estimated to be $1.5 billion. These costs include administrative, analytical, printing, and inventory costs, the latter three including costs to foreign firms. Reformulation costs were not estimated. These costs do not include the voluntary labeling of raw fruit, vegetables, and fish.

Benefits are reduced risk of illnesses such as CHD, cancer, obesity, osteoporosis, and allergic reactions to food ingredients. The value of these benefits are estimated to be $3.6 billion. Estimated costs, benefits, and estimated health effects are shown in Tables 19 and 20 respectively:

TABLE 19.—ESTIMATED COSTS OF THE COMPLIANCE OPTIONS

(In Millions of Dollars Over 20 Years)

Cost type	Option 1	Option 2	Option 3
Mandatory labeling	6 months	12 months	18 months
Administrative	177	93	70
Analytical	195	195	195
Printing	862	600	436
Inventory	306	8	4
Subtotal	1,540	896	705
Voluntary Labeling	136	136	136
Total costs	1,676	1,032	841
Benefits [2]	3,600	3,513	[1] 3,429

[1] Benefits are reduced by discounting only because a 20-year time horizon was used.
[2] Estimate based on life-years saved. Excludes regulation of restaurant menus.

TABLE 20.—ESTIMATED HEALTH EFFECTS [1] (OVER 20 YEARS)

	Effective date		
	6 months	12 months	18 months
Cases avoided:			
Cancer	35,179	33,356	31,533
CHD	4,028	3,962	3,896
Deaths avoided	12,902	12,438	11,973
Life-years gained	80,930	75,199	69,468

[1] Uses lagtimes of 2 and 10 years for the occurrence of CHD and cancer, respectively following a diet change.

FDA has analyzed the total costs and benefits of these proposals and has determined that the costs exceed the $100 million threshold, requiring the agency to declare that these proposals constitute in a major rule as defined by Executive Order 12291. In accordance with the Regulatory Flexibility Act (Pub. L. 96–354), FDA has determined that these proposals will have a significant adverse impact on a substantial number of small entities, including small businesses.

Food Labeling; Declaration of Ingredients and Food Labeling; Declaration of Ingredients, Common or Usual Name for Nonstandardized Foods, Diluted Juice Beverages

AGENCY: Food and Drug Administration, HHS.

ACTION: Proposed rule; delay of statutory effective date.

SUMMARY: The Food and Drug Administration (FDA) is announcing changes in the statutory effective date of the ingredient labeling provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). This action is in response to an amendment of section 10(c) of the 1990 amendments. FDA published proposed rules to implement the ingredient labeling provisions on June 21, 1991 and July 2, 1991.

FOR FURTHER INFORMATION CONTACT: Carl L. Giannetta, Center for Food Safety and Applied Nutrition (HFF–312), Food and Drug Administration, 200 C Street, SW., Washington, DC 20204, 202–485–0229.

SUPPLEMENTARY INFORMATION: Section 7 of the 1990 amendments modified section 403(i) of the Federal Food, Drug and Cosmetic Act (the act) to require the declaration of all ingredients in standardized foods, the declaration of certified color additives in foods, and the declaration, on the information panel, of the percentage of a fruit or vegetable juice in a food purporting to be a beverage containing fruit or

vegetable juice. FDA published proposed regulations to implement these requirements in the **Federal Register** of June 21, 1991 (56 FR 28592) and July 2, 1991 (56 FR 30452), with opportunity for comment through August 5, 1991. Both proposals are part of the Department of Health and Human Services' (DHHS') major initiative to reform the nation's food labeling system and part of DHHS' response to the 1990 amendments.

Although FDA proposed to make the ingredient labeling regulations and percent juice labeling regulations effective on the same date as the mandatory nutrition labeling final rule (i.e., May 8, 1993), the agency pointed out that the 1990 amendments state in section 10(c) that ingredient listing provisions for standardized foods, certified color additives, and percent juice labeling were to take effect 1 year after enactment. Thus, on November 8, 1991, these statutory provisions would be in effect.

In response to the proposals, many comments from the food industry strongly urged FDA to reconsider the effective date for ingredient labeling regulations and percent juice labeling regulations. The comments argued that a November 8, 1991, effective date would not allow the food industry enough time to develop the required labeling and would significantly increase costs because present inventory would have to be discarded. The comments strongly urged FDA to establish a uniform effective date to comply with the effective date for section 403(q) of the act (mandatory nutrition labeling) and section 403(r) of the act claims, which were added by the 1990 amendments. Even though FDA agreed with these comments, it had no authority to provide the requested extensions.

A technical amendment was enacted on August 17, 1991, in which Congress amended the 1990 amendments to delay or modify the effective date of the new ingredient and percent juice labeling requirements. To reflect these changes, the agency is giving notice that a food for which a standard of identity has been established, or with one or more colors required to be certified, that bears a label that was printed before July 1, 1991, and that was attached to the food before May 8, 1993, will not be subject to changes made in section 7(1), which modifies section 403(i) of the act to require that all mandatory as well as optional ingredients in a standardized food be declared, and in section 7(3) of the 1990 amendments, which modify section 403(i) of the act to require the declaration of certified colors. Labels on these foods printed after July 1, 1991 but before the effective date of a final implementing regulation and attached to the food before May 8, 1993, must conform with requirements of the June 21, 1991 proposal. Labels attached to food after May 8, 1993, will be subject to the amended section 403(i) of the act and to FDA's final regulations. Finally, the new ingredient labeling requirements for fruit and vegetable juice beverages will not apply to labels attached to these products before May 8, 1993.

Dated: November 13, 1991.

Michael R. Taylor,

Deputy Commissioner for Policy.

21 CFR Part 101

Food Labeling; Nutrition Labeling; Guidelines for Voluntary Nutrition Labeling; and Identification of the 20 Most Frequently Consumed Raw Fruit, Vegetables, and Fish; Definition of Substantial Compliance; Final Rule

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N-0122]

RIN 0905-AB68

Food Labeling: Nutrition Labeling of Raw Fruit, Vegetables, and Fish; Guidelines for Voluntary Nutrition Labeling of Raw Fruit, Vegetables, and Fish; Identification of the 20 Most Frequently Consumed Raw Fruit, Vegetables, and Fish; Definition of Substantial Compliance

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is: (1) Identifying the 20 most frequently consumed raw fruit, vegetables, and fish in the United States; (2) establishing guidelines for the voluntary nutrition labeling of these foods; and (3) defining "substantial compliance" with respect to the adherence by food retailers to those guidelines. This action is in response to the requirements of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments).

EFFECTIVE DATE: November 8, 1991.

FOR FURTHER INFORMATION CONTACT: Jean A. T. Pennington, Center for Food Safety and Applied Nutrition (HFF-260), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-245-1064.

SUPPLEMENTARY INFORMATION:

I. Background

In response to requirements of the 1990 amendments (Pub. L. 101-535), FDA published in the **Federal Register** of July 2, 1991 (56 FR 30468) a proposal to identify the 20 most frequently consumed raw fruit, vegetables, and fish in the United States; to establish guidelines for the voluntary nutrition labeling of these foods; and to define "substantial compliance" with respect to the adherence by food retailers to those guidelines. FDA requested comments on these proposed regulations and on the proposed guidelines. Interested persons were given until August 1, 1991 to comment. FDA received approximately 40 responses, each of which contained one or more comments, from trade and retail associations, government organizations, retailers, consumer groups, State groups, private organizations, professional societies, and one university. The comments generally supported the proposal. Several comments addressed issues outside the scope of the proposal (e.g., consumer education programs for nutrition labeling) and will not be discussed here. A number of comments suggested modification and revision in various provisions of the proposal. A summary of the suggested changes and the agency's responses follows.

II. Nutrition Labeling of Raw Fruit, Vegetables, and Fish Under the 1990 Amendments

A. Timeframes for Implementation

1. The agency stated in the July 2, 1991 proposal (56 FR 30468 at 30471) that the guidelines for the voluntary nutrition labeling of the 20 most frequently consumed raw fruit, vegetables, and fish, to be issued by November 8, 1991, would be revised, as necessary, after the first report to Congress on retailers, compliance with the voluntary guidelines to reflect other forthcoming labeling regulations. There were requests in several comments that FDA issue all the needed information in its final form for the labeling of raw fruit, vegetables, and fish. Several comments suggested delaying the issuance of the guidelines until the final regulations on serving size, label content, daily intake standards, and label format have been issued. These comments stated that such a delay would allow the agency to develop guidelines for the nutrition labeling of raw fruit, vegetables, and fish that would be consistent with the labeling requirements for processed foods. As a result, it would not be necessary to modify the guidelines when the final rules on those aspects of nutrition labeling are published or to update or replace in-store labeling at that time.

FDA understands the advantages of having all of its regulations that bear on nutrition labeling in place at the time that it issues the guidelines for the nutrition labeling of raw fruit, vegetables, and fish. However, the agency is required by the 1990 amendments to issue these guidelines by November 8, 1991. The guidelines must include information on serving size, label content, daily intake standards (i.e., U.S. Recommended Daily Allowances (U.S. RDA's)), and label format, even though these aspects of the nutrition label are subject to change with the final rules that bear on these matters.

The agency is also required by the 1990 amendments to issue a report to Congress on compliance with the guidelines by retailers by May 8, 1993. This report must be based on actions taken by retailers during the 18 months between November 8, 1991 and May 8, 1993. Realistically, it will take retailers some time after November 8, 1991 before the nutrition labeling programs are in the marketplace, and it will be necessary for the agency to complete its review of the market several months before the report to Congress is due to ensure that the report is submitted on time. Therefore, the time in the marketplace for nutrition labeling of raw produce and fish before assessment of compliance will be closer to 14 to 15 months than 18 months. If the guidelines for nutrition labeling for raw fruit, vegetables, and fish were to be delayed until after the publication of all relevant final regulations (due November 8, 1992), there would be insufficient time to accomplish these tasks and meet the legislative requirement for a report on voluntary compliance by May 8, 1993. Thus, the agency cannot delay issuing the guidelines for the nutrition labeling of raw fruit, vegetables, and fish until the other nutrition labeling regulations are finalized.

2. One comment was concerned with the timeframe for obtaining the labeling data and for providing it in the marketplace. The comment stated that only if FDA can provide the data by November 8, 1991 will there be time for trade associations to distribute it and for retail stores to develop and print the information programs. The comment stated that if the provisions relating to nutrition labeling of raw produce and raw fish are confusing to retailers (because of changes to be made to them), the retailers will not provide the information properly or completely. The comment also noted that the information must be simple and standardized to be useful to consumers. The comment therefore requested that FDA provide the necessary information in final form, with the appropriate serving sizes and in the format desired, before expecting retailers to comply with the regulations.

The agency appreciates these concerns and is providing interim nutrition labeling data for the 60 foods in this final rule (appendices A and B). These data may be used to develop in-store nutrition labeling programs. FDA is providing the data for these foods in serving portions that are generally consistent with the FDA reproposal on serving sizes that is published elsewhere in this issue of the **Federal Register**. The data in appendices A and B include those that should appear on the label as specified in § 101.45(b) for FDA to find the information to be in compliance. Data are provided for calories, protein, fat, carbohydrate, sodium, and percent

U.S. RDA for vitamin A, vitamin C, calcium, and iron. In addition, data are also provided for the dietary fiber content of fruit and vegetables and for the saturated fat and cholesterol content of fish. The guidelines for the voluntary nutrition labeling of raw fruit, vegetables, and fish will, however, be subject to change after the first report to Congress by May 8, 1993 to make them consistent with the final rule for Mandatory Nutrition Labeling.

B. Presentation of the Nutrition Information in Retail Stores

There was general support for the flexibility offered by FDA in presenting the nutrition information to the consumer. Several comments noted the importance of presenting the information in a clear, conspicuous, and prominent manner in close proximity to the commodity. One comment stressed that the information must be easily used and understood by consumers.

3. One comment requested that FDA specifically permit the use of more advanced technology, such as electronic signage, for presenting nutrition information.

The language used in § 101.45(a) does not prohibit more advanced technology, and FDA does not think it necessary to specifically provide for its use. Nutrition information should be available to all consumers, and FDA is concerned that information available only on computer screens, TV monitors, or other electronic media might not be available to all when they wish to use it. Mechanical breakdown of equipment, for example, would make the information unavailable. The 1990 amendments suggest that nutrition information presented through video, live demonstration, or other media may be supplementary, but that signs, brochures, notebooks, or leaflets should be the primary means by which nutrition information is presented to consumers.

C. Label Content

4. Comments regarding label content generally supported FDA's proposal. The comments included requests for voluntary declaration of percent U.S. RDA for protein and expressions of support for voluntary declaration of complex carbohydrates and sugars (although one comment argued that the 1990 amendments require that these nutrients be included in the nutrition label); for flexibility in not requiring declaration of nutrients unlikely to be present in a food; for voluntary declaration of dietary fiber for produce; and for voluntary declaration of fatty acids and cholesterol for fish. The comments also included requests to exempt most produce from labeling for calories from fat, saturated fat, cholesterol, complex carbohydrates, and sugars. These requests argued that most raw produce is low in fat, saturated fat, and cholesterol, and that it is costly to analyze these foods for these components. Comments also pointed out that complex carbohydrates are not yet defined, and that raw produce does not contain added sugars. Although several comments agreed that declaration of thiamin, riboflavin, and niacin should be voluntary (56 FR 30468 at 30471), one comment did not agree that information about these nutrients would not add information that is useful to consumers. One comment was against labeling any foods with calories from fat. One comment supported voluntary labeling of omega–3 fatty acids (sum of eicosapentaenoic and docosahexaenoic acids) for fish.

The agency agrees that the inclusion of percent U.S. RDA for protein should be voluntary. While FDA mistakenly failed to state in proposed § 101.45(b)(1) that the inclusion of this information is voluntary (56 FR 30468 at 30482), the examples for nutrition labeling that FDA provided (56 FR 30468 at 30472) did not include the listing of percent U.S. RDA for protein. The codified language in § 101.45(b)(1) now provides that the percent of U.S. RDA for protein, thiamin, riboflavin, and niacin may be voluntarily declared. Declaration of complex carbohydrates, sugars, dietary fiber, saturated fat, and cholesterol are also voluntary under § 101.45(b)(1).

Although not required in the nutrition labeling of raw produce or raw fish, FDA is providing interim data on the dietary fiber content of fruit and vegetables in appendix A and interim data on the saturated fat and cholesterol content of fish in appendix B. These data, which may be used in nutrition labeling of these foods, are provided by FDA because fruit and vegetables are major sources of dietary fiber, fish contain saturated fat and cholesterol, and the levels of these three food components are of interest and importance to consumers.

The mandatory inclusion of calories from fat, saturated fat, cholesterol, complex carbohydrates, sugars, and omega-3 fatty acids on the nutrition label is a label content issue that is outside the scope of this rulemaking. Comments concerning these components should be submitted in response to the agency's supplementary proposal on mandatory nutrition labeling, which is published elsewhere in this issue of the **Federal Register**.

5. One comment requested that FDA modify the lower level for reporting nutrition labeling values for fish for vitamins A and C, calcium, and iron from 2 percent to 10 percent of the U.S. RDA. The comment stated that fish may contain these nutrients, but that they are not considered important sources. Because the levels of these nutrients are low and variable within some species, the 2 percent cutoff requires costly analysis of fish to be within the technical limits of nutrition labeling.

FDA understands the concern but notes that it is outside the scope of this rulemaking. Comments concerning levels of nutrients in foods and daily values should be submitted in response to the supplementary proposal for mandatory nutrition labeling. The final rule in that proceeding will affect the revision of the guidelines for nutrition labeling of raw fruit, vegetables, and fish. FDA also notes that for consistency of nutrition labeling among all foods, which is necessary to minimize consumer confusion, the lower limits for reporting the nutrient content of foods must not vary among food groups (i.e., the lower limits used for fish should be the same as those used for produce and for processed foods). Finally, FDA believes that it is important for consumers to know which foods can be consumed to increase one's intake, and which foods cannot, of nutrients of public health significance (such as vitamin A, vitamin C, calcium, and iron).

6. One comment stated that carotene, not vitamin A, occurs in fruit and vegetables, and that consumers are aware and knowledgeable of carotene and its role in health. The comment argued that it would be more informative to consumers to label the carotene content (not the vitamin A content) of fruit and vegetables.

FDA believes that this issue is also beyond the scope of this rulemaking. The purpose of this rulemaking is to establish a voluntary program for the nutrition labeling of raw produce and raw fish. The agency believes that such labeling should be consistent for all food products. If this comment is of the opinion that the declaration of vitamin A on the nutrition label should be modified, the comment should be submitted in the mandatory nutrition labeling proceeding. In that rulemaking, FDA is considering under section 403(q) of the Federal Food, Drug, and Cosmetic Act (the act) what nutrients should be included in the nutrition label. If the agency concludes that a change is warranted, it will revise the nutrition labeling regulations and the guidelines for the nutrition labeling of raw fruit, vegetables, and fish to reflect that change.

D. Label Format

7. FDA proposed (56 FR 30468 at 30482) that a simplified format may be used for the nutrition labeling of raw fruit, vegetables, and fish. The comments generally supported the use of a simplified label, but those who evaluated it in more detail noted that it only applies to one fruit (apples) and one vegetable (mushrooms). These are the only two of the 60 foods that have more than half of the required nutrients in insignificant amounts. Comments expressed concern about the qualifying statement, "Not a significant source of ——." because FDA uses the term "significant" when referring to 10 percent or more of the U.S. RDA for a comparative claim, and FDA uses the term "insignificant" when referring to values that are less than 2 percent of the U.S. RDA for nutrition labeling. Comments indicated that the qualifying statement could be misinterpreted to mean that the food contained less than 10 percent U.S. RDA rather than less than 2 percent U.S. RDA. One comment requested liberalizing the definition of "significant" for the simplified label to increase its use. Another comment stated that the term "significant source" was not understood by consumers.

Because of the concern expressed about these issues, FDA has decided to remove proposed § 101.45(b)(2) which deals with use of the simplified label and the qualifying statement for the nutrition labeling of raw fruit, vegetables, and fish. FDA notes that there are only nine nutrients that would have to appear in nutrition labeling for raw produce and raw fish for FDA to find the labeling in compliance. Thus, the labels for these foods are already rather simple. After the final rule on mandatory nutrition labeling is in place, and the agency has modified the guidelines to reflect that final rule, FDA will reconsider the use of the simplified format for raw produce and raw fish. The supplementary proposal on mandatory nutrition labeling will address the use of a qualifying statement for nutrition labeling.

E. Serving Sizes

8. Comments expressed support for serving sizes based on portions commonly consumed and agreed that uniformity in serving sizes will be beneficial for shopping comparisons. The comments also agreed with FDA that there was no need for the statement "servings per container" for raw fruit, vegetables, or fish.

As provided in § 101.45(b)(3), information on servings per container need not be included on the nutrition labeling for raw fruit, vegetables, and fish. However, for raw fruit, vegetables, and fish that are sold in packages with multiple serving per package, the retailer may state the number of servings contained in the package.

9. In the proposal in this proceeding, FDA mentioned the serving sizes (56 FR 30468 at 30472) for the nutrition labeling of raw fruit, vegetables, and fish that conformed to the proposed rule for serving sizes (55 FR 29517, July 19, 1990). In Appendices A and B, FDA has provided interim nutrient values for the 20 most frequently consumed raw fruit, vegetables, and fish in serving portions that are generally consistent with the reproposal for the regulation on serving sizes which is published elsewhere in this issue of the **Federal Register**.

The agency's reproposal on serving sizes is based on product category specific reference amounts instead of standard serving sizes. The reproposal lists the following reference amounts for nutrition labeling of raw fruit, vegetables, and fish: 85 grams (g) for fish, 280 g for watermelon, 55 g for fruit used primarily as ingredient (e.g., avocado), 140 g for all other fruit, 30 g for green onion, and 85 g for other vegetables. Because lemons and limes are used primarily for juice and are not eaten whole like other fruit, the serving considered to be appropriate for these fruits are 1 medium lemon (58 g; 2 ounces (oz)) and 1 medium lime (67 g; 2.5 oz), rather that the reference amount of 140 g, which would be closer to 2 lemons or 2 limes.

The reproposal states that serving sizes for products that come in distinct individual units (e.g., apple, orange, or potato) are to be expressed in the number of units that most closely approximate the reference amount, and serving sizes for products that are usually divided for consumption (e.g., cucumber, honeydew melon) are to be expressed in a fraction of the unit that most closely approximates the reference amount. Products in discrete individual units that weigh 67 percent or more, but less than 200 percent, of the reference amount will constitute one serving. However, a whole unit weighing 200 percent or more of the reference amount may be declared as one serving, if the whole unit can reasonably be consumed at a single-eating occasion. Under the reproposal, serving sizes for multi-serving products are required to be expressed in a common household measure that is most appropriate for the specific product. When oz are used as the serving size, an appropriate visual unit of measure, such as a dimension of a piece, is to be provided.

The reproposal specifies that the label statement regarding serving portion is to be the serving size expressed in common household measures followed by the equivalent metric quantity in parentheses. Serving size may be declared in oz in parentheses, following the metric measure where other common household measures are used as the primary unit for serving size (e.g., 1½ cup (138 g) (5 oz)). One oz is defined to weigh 28 g. Ounce measurements are to be expressed in 0.5 oz increments most closely approximating the reference amount.

10. One comment argued that the proposed serving size for fish (i.e., 4 oz) was "unrealistically small." Other comments favored a 1 oz serving for fish so that consumers could multiply the number of oz they eat by the values for 1 oz.

FDA disagrees with the use of a 1 oz serving because it could confuse consumers and is not consistent with "serving size" as defined by the 1990 amendments. The amendments define serving size to be "* * * an amount customarily consumed * * * expressed in a common household measure that is appropriate to the food * * *." In the reproposal for the serving size regulation, the agency is proposing a reference amount for cooked fish (85 g or 3 oz) that is based on the amount of fish customarily consumed as reported in the Nationwide Food Consumption Surveys conducted by the U.S. Department of Agriculture (USDA). Most comments generally favored a 3 oz portion for fish. They pointed out that a 3 oz serving for fish conforms to the serving used in Seafood Nutri-Facts (Ref. 1), an in-store nutrition labeling program, and that the 1990 amendments directed FDA to take into account the actions taken by food retailers before November 8, 1991, to provide nutrition information on raw agricultural commodities and raw fish to consumers.

11. Several comments requested the use of common household units in addition to, or in place, of g quantities for fruits and vegetables. They stated that consumers would be unfamiliar with the quantity of fruit or vegetable represented by a g weight.

FDA agrees and is allowing for the use of household units (including oz) in addition to the weight of the food in g. The nutrition information provided by FDA for the most frequently consumed raw fruit and vegetables (appendix A) provides the household unit, the weight of a serving in g, and the weight in oz. The nutrition information provided by FDA for the most frequently consumed fish (appendix B) sets forth values that

are for a 3 oz (85 g) portion that has been cooked without fat or seasoning. For several fish (clams, oysters, and scallops), FDA included the number of pieces equivalent to 3 oz.

F. Raw Versus Cooked

12. FDA proposed in § 101.45(b)(5) that nutrition labeling for fruits and vegetables be on a raw basis. Comments generally agreed that nutrient values for fruit and vegetables should be provided on a raw basis, although several comments suggested that values for some vegetables (e.g., potato, sweet corn, sweet potato, green beans, asparagus) should be provided on a cooked basis.

FDA does not agree that nutrition labels for some vegetables should be based on cooked portions because of the need for consistency of labeling within food categories. Therefore, the label values for all fruit and vegetables shall be provided on a raw basis as proposed in § 101.45(b)(5), which is redesignated as § 101.45(b)(4). The values that FDA is presenting in appendix A were derived for fruit and vegetables on a raw basis.

13. FDA proposed in § 101.45(b)(5) that nutritional labeling for fish be on a cooked basis. Several comments argued that all values should be on a raw or as purchased basis to be consistent with the nutrition labeling of the rest of the food supply. However, the majority of the comments on this issue supported using values for fish that are derived on a cooked basis because such values will be most useful to consumers and will prevent the notion that raw fish should be consumed. Several comments argued strongly about the potential for food-borne illness if data were provided for raw fish, and consumers mistook the information as an endorsement for eating raw fish. Several comments noted that the 1990 amendments require that FDA consider programs put in place by retailers, such as the Seafood Nutri-Facts (Ref. 1) which is based on cooked fish. Several comments noted that the label should clearly state that the values are for cooked fish and provide the cooking method or indicate that no fat or seasoning was added. One comment noted that data from analyses of cooked fish are preferred to applying correction factors to data for raw fish.

As provided in proposed § 101.45(b)(5), redesignated as § 101.45(b)(4), FDA continues to believe that nutrient values for fish on a cooked basis (cooked without added fat or seasoning) will be most appropriate under the 1990 amendments because the cooked values are consistent with the nutrient labeling programs that have been developed by retailers for fish, and because cooked values will not encourage the consumption of raw fish. FDA agrees with the comment that the label should state the cooking method used, and, in the nutrition labeling data for fish that FDA has provided in appendix B, the cooking method is stated.

14. One comment noted that the term "cooked without fat or skin" (56 FR 30468 at 30473) was misleading because many fish cannot readily be cooked without their skin (e.g., salmon, trout).

FDA agrees and notes that the nutrient values for fish should be provided on the basis of the cooked, edible portion. The fish need not be cooked without the skin.

G. Nutrient Data

15. There was strong support for the use of single values rather than ranges of values for the nutrition labeling of raw fruit, vegetables, and fish. Comments stated that single values would be more useful and understandable to consumers. One comment suggested that a general statement should be used to indicate to the consumer that nutrient levels vary, and that the values represent averages.

FDA acknowledges that nutrient values for all foods vary. However, the data in appendices A and B on the nutritional labeling of raw fruit, vegetables, and fish reflect nutrient levels for these foods that are available in the United States marketplace, and FDA does not believe that it is necessary to qualify these data. Therefore, FDA is not requiring use of such statements to alert the consumer to nutrient variability. Retailers may optionally use such statements in their brochures, posters, or other methods of displaying the nutrition labeling, if they wish to do so.

16. There was general agreement among the comments that FDA should be responsible for providing the information for the nutrition labeling of raw fruit, vegetables, and fish. The comments also agreed with the use of nutrient values from food composition data bases for the nutrition labeling of these foods. Comments suggested that data from Seafood Nutri-Facts (Ref. 1) and USDA's revised Agriculture Handbook No. 8 might be used for fish and some fruits and vegetables until better data become available. Other comments expressed concern about the lack of reliable data for some fruit, vegetables, and fish and about the cost of generating new data when so many data are already available. One comment suggested that groups or individuals submitting data to FDA for review and evaluation, carefully evaluate and use (if possible) available data and focus new analyses on the foods and nutrients for which information is truly lacking.

Although FDA is not obligated to provide data for the nutrition labeling of the 20 most frequently consumed raw fruit, vegetables, and fish, the agency is providing a chart of interim data (appendices A and B) that retailers may use to initiate their in-store nutrition labeling programs. FDA is providing these data to hasten the development of the in-store programs and the delivery of the information to consumers.

Appendix A lists the 20 most frequently consumed raw fruit and vegetables. The household serving and g and oz edible portion weight of the serving appear below the name of the food. Values are provided for 10 nutrients and food components on a raw basis. Labeling values for 13 fruits (bananas, apples, watermelon, oranges, cantaloupe, grapefruit, strawberries, honeydew melon, avocados, lemons, pineapple, sweet cherries, and kiwifruit) and 17 vegetables (potatoes, iceberg lettuce, tomatoes, onions, carrots, celery, broccoli, green cabbage, cucumbers, bell peppers, cauliflower, leaf lettuce, mushrooms, green beans, radishes, summer squash, and asparagus) were obtained primarily from the Produce Marketing Association (PMA). These values, which were calculated according to the procedures in the FDA manual "Compliance Procedures for Nutrition Labeling" (Ref. 2), were submitted to FDA for review and evaluation. Data for seven fruits (grapes, peaches, pears, nectarines, plums, tangerines, and limes) and three vegetables (sweet corn, sweet potatoes, green onion), which reflect mean values, were derived from USDA Agriculture Handbook No. 8–9 (fruits and fruit juices) (Ref. 3) and No. 8–11 (vegetables and vegetable products) (Ref. 4), and other sources.

Appendix B lists the 20 most frequently consumed raw fish. The serving portion is a 3 oz (85 g) edible portion, cooked. Values are provided for 11 nutrients and food components. The data, which reflect mean values, were derived from Seafood NutriFacts (Ref. 1) (which is based on USDA data), USDA Agriculture Handbook No. 8–15 (finfish and shellfish products) (Ref. 5), and other sources.

FDA stated in the proposal (56 FR 30468 at 30474) that sources of nutrient data for the nutrition labeling of raw fruit, vegetables, and fish could include: (1) Analytical data previously generated by trade associations that were reviewed by FDA and found to be acceptable; (2) data generated from

analyses initiated by retailers, trade associations, or other groups that are submitted to FDA for review and evaluation; and (3) analytical data that have been previously generated by various groups and that are available in the literature, data bases, or elsewhere, which retailers, trade associations, or other groups gather (with appropriate documentation and statistical information) and submit to FDA for review and evaluation.

If FDA does not receive improved data for the seven fruits, the three vegetables, and all 20 fish, the agency will subject the data for these foods that were used in appendices A and B to the FDA compliance calculations and publish the resulting labeling values in the next edition of the charts. As stated in § 101.45(i), which FDA is adding in this final rule to provide for these appendices, FDA intends to revise and publish, with an opportunity for comment, the charts of nutrition labeling data for the 20 most frequently consumed raw fruit, vegetables, and fish at least every 2 years in the Federal Register as new data are derived or received and accepted. This activity will be coordinated with the biennial report to Congress on compliance with voluntary guidelines as long as nutrition labeling of raw produce and fish remains a voluntary activity. The agency has decided not to publish the nutrition labeling values in the CFR at this time because the values are interim and subject to change on a frequent basis. Publication in the CFR may lead to confusion about appropriate values. FDA may wish to reconsider publication in the CFR as newer and better data are submitted to the agency.

17. There was general support for the use of adequately supported and derived composite data. The comments stated that composite data provide a consistent standard for nutrition labeling among stores and a decreased burden for retailers. However, comments also noted that composite labeling could be misleading for some species of fish. For example, one comment noted that composite data for salmon are not specific enough to be useful to consumers because of the differences in fat content among the major species of salmon. The comment suggested that FDA should specify the predominant species of salmon and several other fish listed among the 20 most frequently consumed in the United States.

In response, FDA has identified salmon, mackerel, trout, and crab as encompassing several species with differing nutrient content and has specified in § 101.44(c) the major types of salmon (Atlantic/coho salmon), mackerel (Atlantic/Pacific and jack mackerel), trout (rainbow trout), and crab (blue crab) consumed in the United States (Refs. 6 and 7). The nutrition labeling data in appendix B pertain to these specific types, and the nutrition label should use these specific names.

18. One comment raised a question as to whether attempts could be made to block imports of Canadian produce to the United States on the grounds that their nutrient content was at variance with the nutrition profile generated for produce sold in the United States.

It is not FDA's intention that nutrition labeling be used as a trade barrier. The nutrient data bases generated and accepted for nutrition labeling purposes for raw produce and fish should encompass all products normally consumed in the United States, including imported products. If for some reason a new cultivar of a fruit or vegetable is introduced to the United States, or the levels of importation of fruit or vegetables change, the composite nutrition labeling data should be modified to reflect the change. Nutrition labeling values are expected to change over time to reflect what Americans are consuming. FDA will not attempt to block imports of specific raw fruit, vegetables, and fish to the United States if the nutrient content of these foods does not conform to the composite nutrition labeling data accepted by FDA for these foods.

H. Statistical Treatment of Nutrient Data

19. FDA stated in the July 2, 1991 proposal (56 FR 30468 at 30475–30476) that values for nutrition labeling should be determined according to the procedures outlined in the FDA manual "Compliance Procedures for Nutrition Labeling" (Ref. 2). Several comments expressed a preference for use of mean values for the nutrition labeling of raw fruit, vegetables, and fish rather than the compliance calculations suggested by FDA. There were also comments concerning the confidence intervals of label values based on FDA compliance calculations. Several comments were in favor of current prediction intervals (± 20 percent), while several others offered statistical alternatives to the FDA compliance procedures in the manual.

FDA notes that it is revising its "Compliance Procedures for Nutrition labeling" (Ref. 2), and that some of the concerns expressed about statistical prediction intervals and use of mean values may be resolved with the forthcoming revised manual. FDA requests that data developed for purposes of nutritional labeling conform to the instructions provided in the manual (or subsequent revisions of this manual) for the following reasons:

1. Mean and median values for nutrients and food components do not provide information about the variability of the values. It is not possible, because of space considerations, to put information about standard errors or standard deviations on food labels, and even if it were, the consumer would probably be confused by them. The use of compliance calculations allows the variance to be considered when developing the nutrient values used on food labels. The calculations thus aid the consumer by providing conservative label values in which the consumer can have a high degree of confidence.

2. The use of mean and median nutrient values for nutrition labeling may be misleading. For nutrients that are normally distributed (e.g., have a normal distribution of values around the mean), there is a 50 percent chance that a mean or median value on the label would be above, or below, the actual levels of nutrients in the food. For example, for vitamins, minerals, and protein, there is only a 50 percent chance that if the mean or median values are used for nutrition labeling, they would present the minimum amounts of the nutrient present in a serving of the food. It is equally as likely that the food contains a smaller amount of the nutrient than is declared, as it is that the food contains more of the nutrient. Similarly for calories, cholesterol, fat, and sodium, there is only a 50 percent chance that if the mean or median levels are used for nutrition labeling, they would represent the minimum amount of these substances per serving. Moreover, mean values are influenced by extreme values (e.g., a few outlying values may greatly increase a mean value). The probability that a serving of food will actually contain mean levels of nutrients or food components decreases as the variance increases and as the number of outliers increases. Thus, nutrition labeling values based on mean or median values may provide a low level of confidence.

3. The compliance calculations suggested by FDA give the consumer reasonable assurance that the vitamins, minerals, and protein will be present at levels that are at least 80 percent of label claim, and that calories, fat, cholesterol, and sodium will be present at levels that are no greater than 120 percent of label claim. The use of these calculations is therefore of benefit to the consumer and provides consumer protection.

4. It is important that all foods in the marketplace be labeled consistently. The same procedures that are used for packaged, processed foods should be used for raw produce and for raw fish. The consumer may be confused and deceived by inconsistent labeling of different products. The compliance calculations provided by FDA for nutrition labeling have been recommended and used since 1973.

5. Consumers and nutrition professionals benefit from the improved data bases developed by industry and trade associations and other groups. The use of FDA compliance calculations provides retailers, retail trade associations, and other trade associations with an incentive to continue routine analysis of foods, to analyze more samples, and to improve analytical methods. More analyses (properly done) allow researchers to more clearly define the levels of nutrients in foods and to identify outliers. Often, more analyses lead to a better estimate of the variance or allow the variance to be more clearly defined. As better estimates of the variance of nutrient levels are obtained, the values that can be used for nutrition labeling become more informative.

I. Submission of Data to FDA and Acceptance of Data by FDA

20. There was support for FDA review and evaluation of labeling data submitted to the agency, although one comment, which said that FDA's approach was impractical and burdensome, favored certification of privately generated data bases. One comment requested clarification regarding the submission of data to FDA and the review process for the data. There were several comments related to concerns about inconsistency of data among stores because of several sets of accepted data for a commodity. One comment asserted that approved composite data bases should be made available to all retailers, whether or not they are members of the association developing the data. Another comment asked if FDA will have a system for tracking data, and how the data base will be made available. Another comment asked about acceptance of data sets for wild, as opposed to farmed, fish and species of fish that were more specific than those included in the top 20.

To promote uniformity and consistency of values among stores, FDA is providing in Appendices A and B to this final rule the nutrition labeling data for the 20 most frequently consumed raw fruit, vegetables, and fish. FDA will review and evaluate data that are submitted to the agency for the 20 most frequently consumed raw fruit, vegetables, and fish and for other raw fruit, vegetables, and fish. FDA is providing in § 101.45(i) that, at least every two years, it intends to publish in the **Federal Register**, and to provide an opportunity for comment on, updates of these data sets or a notice that the data sets have not changed from the previous publication. FDA may publish revisions of the data sets more frequently than every two years if better data become available. FDA will keep a log and files of all data submitted and accepted for raw fruit, vegetables, and fish.

FDA will not accept multiple data sets for the nutrition labeling of the 60 commodities. If new data are submitted for a commodity, and FDA judges those data to be superior to previous data, the agency will publish the newer data to replace the old with an opportunity for comment. FDA may decide to replace data for one or more or all nutrient values for a fruit, vegetable, or fish.

As stated in § 101.45(f), accepted data (if not replaced) may be reaccepted by FDA at the end of 10 years. FDA has stated in § 101.45(i) that data accepted by the agency for nutrients other than those listed in appendices A and B for the 20 most frequently consumed raw fruit, vegetables, and fish, and data accepted by FDA for other raw fruit, vegetables, and fish, will be available upon request to FDA (Division of Nutrition, 200 C St. SW., Washington, DC 20204).

J. Identification of the 20 Most Frequently Consumed Raw Fruit, Vegetables, and Fish in the United States

Comments supported a national list (rather than regional lists) for the most frequently consumed raw fruit, vegetables, and fish. There was general support for FDA's definition of "most frequently consumed" and the identification of the foods based on sales, production, and consumption data. Several comments noted a minor misstatement in the proposal (56 FR 30468 at 30476, III.C.1., third paragraph). The statement should have been that the agency has interpreted the phrase "most frequently consumed" to mean those varieties purchased raw (not consumed raw) in the largest quantities by the United States population. FDA does not believe that this minor misstatement had any substantive effect.

21. Several comments wanted a longer list of fish (e.g., 30 rather than 20) to include more species, more regional variation, and a distinction between farmed and wild seafood. As noted previously, one comment wanted salmon to be specified by the predominant type (e.g., Atlantic/coho) because composite nutrient values for all salmon would not be useful to consumers. One comment questioned whether raw, shucked oysters would be included for nutritional labeling. One comment noted that rockfish is a local name in Maryland and Virginia for striped bass and asked for clarification of this fish name for consumers.

Fish that are not among the 20 most frequently consumed may be nutrition labeled. Nutrition labeling data for other fish or for specific varieties of fish that are among the top 20 may be submitted to FDA for review and evaluation or may be used subject to § 101.45(h). FDA does not have sufficient data to provide separate information for farmed and wild fish. However, such data, if available, should be submitted to FDA for review and evaluation and possible acceptance for nutrition labeling. Several of the fish (salmon, mackerel, crab, and trout), identified in the proposal (§ 101.44(c)) as being among the 20 most frequently consumed, have been more specifically defined as Atlantic/coho salmon, Atlantic/Pacific & jack mackerel, blue crab, and rainbow trout. The nutrient values that apply specifically to these species are less variable and, therefore, more useful to consumers. Oysters, which are listed among the 20 most frequently consumed fish, include raw, shucked oysters.

According to FDA's Fish List (Ref. 8), rockfish have many common and regional names, and the term "rockfish" is, indeed, used in some areas for striped bass. FDA hopes that over time, at least in part through nutrition education programs, consistency can be achieved in the names of fish used in retail stores. The fish names listed in appendix B should be used for nutrition labeling at the retail level because these names are accepted nationally and are used by FDA (Ref. 8). FDA believes that it would be misleading to place nutrition labeling data for rockfish under the name of "rockfish" in some areas and under "striped bass" in other areas. Consistency in nutrition labeling of raw produce and fish among stores throughout the United States is essential if the program is to be beneficial to consumers. Consumers may shop in different stores in different areas. They should see the same fish names and nutrition labeling values for the same fish no matter where they shop. Retailers may, if they feel it is necessary, provide clarification to customers about local fish names. Such clarification may be presented as a parenthetical name or a footnote on the

labeling information that is presented in the store. For example, the labeling information might state: "Rockfish (locally known as Striped Bass)."

22. One comment argued that when and where fish are packaged should not be the determining factors in deciding whether fish are to be included in the voluntary labeling program. The comment noted that raw fish may be packaged both by manufacturers and by retailers and asked that there not be different treatment of products identical in species, form, packaging material, and presentation to the consumer. The comment also asked that the definition of fish be extended to include molluscan shellfish and other finfish market cuts such as steaks, chunks, and fillets.

In response to the comment, FDA believes that it is appropriate to clarify which fish, under the 1990 amendments, may voluntarily be labeled and which are required to be nutrition labeled. Fish included under the voluntary nutrition labeling program are: raw (i.e., not heat treated), whole or market cuts of finfish and shellfish; raw, whole, peeled, shelled, or shucked shrimp, scallops, oysters, clams, and lobster; and shelled or unshelled lobster, crab, and shrimp that have been thermally processed. These fish are generally sold in fish stores or in the fresh fish section of grocery stores. They may be frozen or iced. They are generally not packaged or packaged by the retailer in paper or with cellophane and plastic or paperboard tray. Raw, frozen fish that are packaged by a manufacturer (usually in a box with a printed label) and sold in the frozen food case of a grocery store are subject to mandatory nutrition labeling.

K. Substantial Compliance Definition and Determination

23. There was general agreement among comments with the 90 percent compliance requirement for individual stores. There were questions about how the sample of 2,000 stores was derived, and about how representative the sample would be of the United States marketplace. One comment stated that rural America had been overlooked. Several comments feared that the margin of error in the estimation of substantial compliance could over estimate compliance (i.e., that an estimate of 60 percent compliance could really be 56 percent). Several comments said that a chain was 11 or more (not four or more) stores under common ownership.

FDA responds by noting that sample size is study specific and is based on two factors, survey design and desired precision. The survey design incorporates different aspects of the study (in this case, annual sales, proportion of chain versus independent stores, regional variability, and county size) to insure representativeness of the overall population of stores. The desired precision is the degree of certainty of estimates to minimize sampling error.

The selection of a sample of 2,000 stores was based upon the survey design and the assurance that a sample of 2,000 stores provides a relatively narrow margin of uncertainty around an observed compliance level (e.g., a maximum of ± 4 percent for 50 percent compliance and a maximum of ± 3 percent for 60 percent compliance), with an acceptable degree of statistical confidence (95 percent). The percent error decreases as the percent compliance increases. Every estimation of percent compliance has a degree of error; however, the error could be positive or negative. For an identified compliance level of 60 percent and a sample of 2,000, the chances are 95 in 100 that the actual level falls between 56.1 percent and 63.9 percent. Any further increases in sample size are not necessary, because the percentage of further reductions in uncertainty achieved would only be small and diminishing.

Based on the characteristics of the retail grocery distribution system, which were shown in Table 8 of the proposed regulation (56 FR 30468 at 30481) and discussed in the text (56 FR 30468 at 30477), chain versus independent ownership and store volume are key factors in constructing a survey sample that is representative of the total distribution system. Representativeness by rural versus urban areas is further assured by allocating the store sample in proportion to food sales in counties that are highly urbanized, relatively urbanized, rural, and very rural. The specific county size definitions and classifications are based on the 1980 United States census of the population.

Although various definitions of a chain (e.g., 4, 8, or 11 stores under common ownership) are used within the retail food industry, after considering the comments, FDA has decided not to change its definition of a "chain" as four or more stores. This definition is commonly accepted and is used by the major marketing firm that will serve as the contractor for the survey that FDA will undertake to assess compliance with the guidelines.

24. Opinion was divided among the comments about the definition of substantial compliance as "at least 60 percent of all stores that are evaluated in compliance" with the guidelines in § 101.45. Some comments, especially those from retailers and retailer organizations, felt it was appropriate. Others, especially those from consumer groups and professional societies, wanted a higher value of 80 to 90 percent.

FDA understands the concerns of retailers in initiating a new program and the desire of consumer groups to ensure that consumers have access to the information. FDA is concerned that it may take some time to get the programs going and does not want to judge them unfairly, particularly at the onset. As evidenced by the discussion in the preamble to the proposed rule (56 FR 30468 at 30478), FDA carefully considered the statutory criteria for defining "substantial compliance." FDA continues to believe that the criterion that it proposed represents an appropriate balance among the factors that Congress directed it to consider. To meet the 60 percent criterion, well over half of all covered stores will have to provide nutrition labeling. Moreover, if this criterion is met, based on the size and the market share of the stores that FDA will survey, nutrition labeling will be provided for well over half of the sales of raw produce and raw fish in this country. FDA believes that this level of compliance and of providing information to consumers is fairly characterized under the criteria in the law as substantial. Moreover, while the comments that disagreed with FDA's standard asserted that a higher percentage was appropriate, none provided a meaningful basis for a change or demonstrated that FDA's criterion was inconsistent with the act. Therefore, FDA is adopting the standard for "substantial compliance" that it proposed.

25. Several comments requested that substantial compliance be determined separately for raw produce and fish. They stated that the produce section of a store should not be considered to be out of compliance if the fish section did not meet the requirements.

FDA agrees with these comments because of the inherent separateness between the produce industry and the fish industry. The two groups are served, for the most part, by separate retail and trade associations. Also, produce and fish are generally sold in different locations in the grocery stores. FDA believes that the failure to achieve substantial compliance for either produce or fish should not hinder the voluntary nutrition labeling program for the other. FDA has clarified in proposed § 101.43(a) that the raw produce and raw fish in individual stores are to be evaluated separately for compliance and has specified in proposed § 101.43(d)

that substantial compliance is to be evaluated separately for raw produce and for raw fish. FDA will make both evaluations on the basis of samples of 2,000.

L. Exemptions

26. One comment requested that the exemption for small United States operations be matched by a requirement that United States retailers not pass the labeling responsibility to small volume third country suppliers of produce.

The 1990 amendments specify that it is the responsibility of the retailer, not the supplier, to provide the nutrition labeling information to consumers. In addition, FDA is supplying the necessary interim nutrition labeling information for retailers. Because of these facts, FDA believes that no burden regarding nutrition labeling will fall upon small volume third country suppliers of produce, and, hence, there is no need for an exemption for them.

27. One comment stated that the exemptions specified in the law for small businesses, restaurants, delis, self-service food bars, and foods prepared and processed at the store must be included in the final regulation. One comment felt that FDA should clarify that all raw fruit, vegetables, and fish not within the top 20 are exempt from nutrition labeling. One comment requested clarification that mixtures of fruits and vegetables (e.g., melon cups, fruit salad, vegetable trays with dip, salads) are exempt from labeling requirements. Another comment said that nutrition labeling of minimally processed raw produce packaged with a separate packet of sauce or dressing should be voluntary.

FDA has reviewed the exemptions from nutrition labeling specified in the 1990 amendments as they pertain to the nutrition labeling of raw fruit, vegetables, and fish (56 FR 30468 at 30478). Exemptions from mandatory nutrition labeling of foods are fully covered in the supplementary nutrition labeling proposal.

FDA notes that section 403(q)(5)(A)(ii) of the act provides exemptions from nutrition labeling for food "which is processed and prepared primarily in a retail establishment, which is ready for human consumption, which is of the type described in section 403(q)(5)(A)(i) of the act, and which is offered for sale to consumers but not for immediate human consumption in such establishment and which is not offered for sale outside such establishment." FDA considers in-store prepared packages that contain mixtures of fruit and vegetables (e.g., carrot and celery sticks; slices of mushrooms, green pepper, and cucumber; cantaloupe, honeydew, and watermelon balls; slices of apples, pineapple, and kiwifruit) to be prepared for immediate consumption. They therefore fall within the description offered in section 403(q)(5)(A)(ii) of the act and are exempt from nutrition labeling. Because such products are exempt from nutrition labeling, FDA will not consider them when making determinations of compliance.

Raw fruits or vegetables that are sold with separate packets of sauce or dressing are not included in the voluntary nutrition program. Such products intended for immediate consumption are exempt from nutrition labeling. Such products requiring cooking with the addition of a sauce fall under the requirements for mandatory nutrition labeling.

28. One comment recommended that FDA raise the annual gross sales requirement for small business from $50,000 to $300,000 to assure that small business can avail themselves of this exemption.

The 1990 amendments specify that retailers shall be exempt if they have "annual gross sales made or business done in sales to consumers which is not more than $500,000 or has annual gross sales made or business done in sales of food to consumers which is not more than $50,000 * * *". These legislative values cannot be changed administratively. The values are discussed fully in the supplementary mandatory nutrition labeling proposal.

M. Costs of Program Implementation

29. FDA estimated (56 FR 30468 at 30479) the cost of program implementation to be from $100 to $165 million over 20 years for compliance of at least 60 percent for 99,000 stores. Several comments stated that costs estimated by FDA for the nutrition labeling of raw fruit, vegetables, and fish were conservative because the life of a sign in a grocery store is only 6 months to a year (not 5 years), and because use of an interim program (until the issuance of revised guidelines) will cause the cost of compliance to increase because signs and labels will need to be updated when final regulations and formats are established. Costs were estimated by these comments to be about $150 to $200 per year per store.

FDA has considered the estimates provided by several of the comments and notes that at a yearly cost of $150 for 60 percent compliance, the 20-year cost would be $117 million (at a 5 percent discount rate), and at a yearly cost of $200 for 60 percent compliance, the 20-year cost would be $155 million (at a 5 percent discount rate). FDA is modifying its estimates of the cost of this rule accordingly.

III. Conclusion

In response to comments submitted regarding the proposal for the voluntary nutrition labeling of raw fruit, vegetables, and fish (56 FR 30468), FDA has modified §§ 101.43, 101.44, and 101.45. The agency has adopted the provisions of § 101.42 and other parts of §§ 101.43 through 101.45 as proposed because the agency did not receive any comments concerning them or because, as explained above, the comments received did not provide any basis to justify a change. The following summarizes the changes being made to §§ 101.43 through 101.45 by this final rule:

FDA has modified § 101.42(e) and (f) and § 101.43(a) to clarify that substantial compliance will be assessed separately for raw agricultural commodities (i.e., raw fruit and vegetables) and for raw fish.

In § 101.43(b), FDA has changed the phrase "* * * raw fruit, vegetables, and fish * * *" to "* * * raw fruit and vegetables and of raw fish * * *" to clarify that substantial compliance will be assessed separately for raw agricultural commodities and for raw fish.

As discussed above, section 101.43(d) is being added and states "FDA will evaluate substantial compliance separately for raw agricultural commodities and for raw fish."

In § 101.44(c), the types of salmon, mackerel, crab, and trout that are among the 20 most frequently consumed raw fish are being more precisely identified, so that the nutrient values will be of greater use to consumers. These fish are now being described as Atlantic/coho salmon, Atlantic/Pacific and jack mackerel, blue crab, and rainbow trout.

In § 101.45(b)(1), as explained above, FDA is changing the statement "Thiamin, riboflavin, and niacin may be declared in the nutrition labeling" to "The percent U.S. RDA for protein, thiamin, riboflavin, and niacin may be declared in the nutrition labeling." A statement has been added that declaration of complex carbohydrates, sugars, dietary fiber, saturated fat, and cholesterol is voluntary.

As explained above, proposed § 101.45(b)(2), which concerned the use of a simplified label and a qualifying statement, has been removed. Sections 101.45(b)(3) through (b)(5) have been redesignated as § 101.45(b)(2) through (b)(4).

In redesignated § 101.45(b)(2), in the first sentence of this paragraph, the phrase "for the full or simplified formats" is being removed because the discussion about the simplified format has been removed.

In § 101.45(e), in the first sentence, the word "booklet" is being replaced by "manual" to be consistent with the text of the **Federal Register**. The phrase "(or subsequent revisions of this manual)" is being inserted after the name of the manual. In the second sentence, the word "It" was replaced by "The manual" for clarification.

In § 101.45(f), in the first sentence, the phrase "* * * of the data base * * *" is being replaced by "* * * of a submitted data base * * *" for clarification.

In § 101.45(f), the following is being added to the end of the second sentence, "* * * or until another data base on the same commodity is submitted to FDA and found to be superior." In addition, in § 101.45(f), in the fourth sentence, the following is being inserted after "unless," "* * * the data base is being superseded by another on the same commodity or * * *." These changes reflect the fact that, as discussed above, FDA will not accept multiple data sets but will only maintain the best data available.

In § 101.45(h), the word "raw" is being inserted before "fruit" for clarification.

As discussed above, section 101.45(i) is being added. This new section states: "FDA will publish, and provide an opportunity for comment on, updates of the nutrition labeling data for the 20 most frequently consumed raw fruit, vegetables, and fish (or a notice that the data sets have not changed from the previous publication) at least every 2 years in the **Federal Register**. FDA accepted data for other raw fruit, vegetables, and fish or for other nutrients are available from the Division of Nutrition, Center for Food Safety and Applied Nutrition, 200 C St. SW., Washington, DC 20204."

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Economic Impact

The food labeling reform initiative, taken as a whole, will have associated costs in excess of the $100 million threshold that defines a major rule. Therefore, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA has developed one comprehensive regulatory impact analysis (RIA) that presents the costs and benefits of all of the food labeling provisions taken together. The RIA is published elsewhere in this issue of the **Federal Register**.

The costs of compliance with this final rule alone are discussed in section II.M. above. FDA has estimated the costs that may be incurred as a result of the provisions of the 1990 amendments covered by this final rule to be between $117 million to $155 million. FDA welcomes comments on these cost estimates.

[1] Less than 2% U.S. RDA.

Notes

Data sources:

Produce Marketing Association (all data except as noted below).

USDA Revised Agriculture Handbook No 8-9 (Fruits and Fruit Juices, 1982) and 8-11 (Vegetables and Vegetable Products, 1984) for grape, peach, pear, nectarine, plum, tangerine, lime, sweet corn, sweet potato, and green onion; dietary fiber for pineapple, tomato, and carrot; dietary fiber for grape and plum based on similar foods.

Dietary fiber for nectarine, tangerine, lime, and green onion from *McCance and Widdowson's The Composition of Foods* by A.A. Paul and D.A.T. Southgate, 4th revised ed., Elsevier/North-Holland Biomedical Press, NY, 1978 or *Nutrient Content of Food Portions* by J. Davies and J. Dickerson, The Royal Society of Chemistry, Cambridge, U.K., 1991.

Serving portion weights in oz from PMA were multiplied by 28 to obtain g weights; 55 g were used for 2 oz, and 85 g were used for 3 oz. Ounces were rounded to the nearest 0.5 oz for the chart. Serving portions weights in g from USDA were divided by 28 to obtain oz; oz were rounded to the nearest 0.5 oz.

Values were rounded in accordance with 21 CFR 101.9. Percent U.S. RDA was based on 5,000 IU for vitamin A, 60 milligrams (mg) for vitamin C, 1,000 mg for calcium, and 18 mg for iron.

Avocado data were derived from two data sets and are based on California varieties.

VIII. Appendix B

[Nutrition labeling accepted by FDA for the 20 most frequently consumed fish (August 1991)]

	Kilocalories	Protein (g)	Carbohydrates (g)	Fat (g)	Saturated Fatty Acid (g)	Cholesterol (mg)	Sodium (mg)	Percent U.S. RDA			
								Vitamin A	Vitamin C	Calcium	Iron

[1] Less than 2% U.S. RDA.
[2] Cooked without fat or seasoning.

Notes

Data sources:

Seafood Nutri-Facts by the Food Marketing Institute and the National Fisheries Institute, 1988 [all values except vitamin A, vitamin C, calcium, iron].

USDA Agriculture Handbook No. 8-15 (Finfish and Shellfish Products, 1987) and NOAA (National Oceanic and Atmospheric Administration) Technical Memo NMFS F/SEC-11 (1981) (vitamin A, vitamin C, calcium, iron).

([1]) = assumed less than 2 U.S. RDA (no data available).

Atlantic/coho salmon was selected for labeling because most pink salmon is canned, and most sockeye salmon is exported to Japan. Atlantic/Pacific and jack mackerel were selected for labeling because consumption of Spanish mackerel is low. Personal communication with L. Weddig of National Fisheries Institute, August 15, 1991.

Nutrient values were averaged for Atlantic and coho salmon and for Atlantic and Pacific and jack mackerel.

Atlantic cod was used for cholesterol and sodium; Pacific cod would be 40 mg cholesterol and 75 mg sodium.

Values were rounded in accordance with 21 CFR 101.9. Percent U.S. RDA was based on 5,000 IU for vitamin A, 60 mg for vitamin C, 1,000 mg for calcium, and 18 mg for iron.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Subpart C is added to read as follows:

Subpart C—Specific Nutrition Labeling Requirements and Guidelines

Sec.

101.42 Nutrition labeling of raw fruit, vegetables, and fish.
101.43 Substantial compliance of food retailers with the guidelines for the voluntary nutrition labeling of raw fruit, vegetables, and fish.
101.44 Identification of the 20 most frequently consumed raw fruit, vegetables, and fish in the United States.
101.45 Guidelines for the voluntary nutrition labeling of raw fruit, vegetables, and fish.

Subpart C—Specific Nutrition Labeling Requirements and Guidelines

§ 101.42 Nutrition labeling of raw fruit, vegetables, and fish.

(a) The Food and Drug Administration (FDA) urges food retailers to provide nutrition information, as provided in § 101.9(c), for raw fruit, vegetables, and fish at the point-of-purchase. If retailers choose to provide such information, they should do so in a manner that conforms to the guidelines in § 101.45.

(b) In § 101.44, FDA has listed the 20 varieties of raw fruit, vegetables, and fish that are most frequently consumed during a year and to which the guidelines apply.

(c) FDA has also defined in § 101.43, the circumstances that constitute substantial compliance by food retailers with the guidelines.

(d) By May 8, 1993, FDA will issue a report on actions taken by food retailers to provide consumers with nutrition information for raw fruit, vegetables, and fish under the guidelines established in § 101.45.

(1) The report will include a determination of whether there is substantial compliance, as defined in § 101.43, with the guidelines.

(2) In evaluating substantial compliance, FDA will consider only the 20 varieties of raw fruit, vegetables, and fish most frequently consumed as identified in § 101.44.

(e) If FDA finds that there is substantial compliance with the guidelines for the nutrition labeling of raw fruit and vegetables or of fish, the agency will so state in the report, and the guidelines will remain in effect. FDA will reevaluate the market place for substantial compliance every 2 years.

(f) If FDA determines that there is not substantial compliance with the guidelines for raw fruit and vegetables or for raw fish, the agency will at that time issue proposed regulations requiring that any person who offers raw fruit and vegetables or fish to consumers provide, in a manner prescribed by regulations, the nutrition information required by § 101.9. Final regulations would have to be issued 6 months after issuance of proposed regulations, and they would become effective 6 months after the date of their promulgation.

§ 101.43 Substantial compliance of food retailers with the guidelines for the voluntary nutrition labeling of raw fruit, vegetables, and fish.

(a) The Food and Drug Administration (FDA) will judge a food retailer who sells raw agricultural commodities or raw fish to be in compliance with the guidelines in § 101.45 with respect to raw agricultural commodities if the retailer displays or provides nutrition labeling for at least 90 percent of the raw agricultural commodities listed in § 101.44 that it sells, and with respect to raw fish if the retailer displays or provides nutrition labeling for at least 90 percent of the types of raw fish listed in § 101.44 that it sells. To be in compliance, the nutrition labeling shall:

(1) Be presented in the store or other type of establishment in a manner that is consistent with § 101.45(a);

(2) Be presented in content and format that are consistent with § 101.45(b); and

(3) Include data that have been provided by FDA (see § 101.45(i)), that have been accepted by FDA (see § 101.45 (c), (f), and (g)), or that are consistent with § 101.45 (d) and (e) and have not been found to be out of compliance after a review under § 101.9(e) (see § 101.45(h)).

(b) To determine whether there is substantial compliance by food retailers with the guidelines in § 101.45 for the voluntary nutrition labeling of raw fruit and vegetables and of raw fish, FDA will select a representative sample of 2,000 stores, allocated by store type and size, for raw fruit and vegetables and for raw fish.

(c) FDA will find that there is substantial compliance with the guidelines in § 101.45 if it finds based on paragraph (a) of this section that at least 60 percent of all stores that are evaluated are in compliance.

(d) FDA will evaluate substantial compliance separately for raw agricultural commodities and for raw fish.

§ 101.44 Identification of the 20 most frequently consumed raw fruit, vegetables, and fish in the United States.

(a) The 20 most frequently consumed raw fruit are: Banana, apple, watermelon, orange, cantaloupe, grape, grapefruit, strawberry, peach, pear, nectarine, honeydew melon, plum, avocado, lemon, pineapple, tangerine, sweet cherry, kiwifruit, and lime.

(b) The 20 most frequently consumed raw vegetables are: Potato, iceberg lettuce, tomato, onion, carrot, celery, sweet corn, broccoli, green cabbage, cucumber, bell pepper, cauliflower, leaf lettuce, sweet potato, mushroom, green onion, green (snap) bean, radish, summer squash, and asparagus.

(c) The 20 most frequently consumed raw fish are: Shrimp, cod, pollack, catfish, scallop, Atlantic/coho salmon, flounder, sole, oyster, orange roughy, Atlantic/Pacific and jack mackerel, ocean perch, rockfish, whiting, clam,

haddock, blue crab, rainbow trout, halibut, and lobster.

§ 101.45 Guidelines for the voluntary nutrition labeling of raw fruit, vegetables, and fish.

Nutrition labeling for raw fruit, vegetables, and fish listed in § 101.44 should be presented to the public in the following manner:

(a) Nutrition labeling information should be displayed at the point of purchase by an appropriate means, including by affixing it to the food, by posting a sign, or by making the information readily available in brochure, notebook, or leaflet form in close proximity to the foods. The nutrition labeling information may also be supplemented by a video, live demonstration, or other media.

(b) Nutrition information should be provided on the label or in labeling in accordance with § 101.9, as modified by the following guidelines:

(1) The percent U.S. RDA for protein, thiamin, riboflavin, and niacin may be declared in the nutrition labeling. Declaration of complex carbohydrates, sugars, dietary fiber, saturated fat, and cholesterol is also voluntary.

(2) Nutrition labeling information may be presented on individual labels or in charts in vertical columns or in lines. When lines are used, any subcomponents declared should be listed parenthetically after principal components (e.g., saturated fat should be parenthetically listed after fat).

(3) Declaration of the number of servings per container need not be included in nutrition labeling of raw fruit, vegetables, and fish.

(4) The nutrition label data should be based on raw edible portion for fruit and vegetables and on a cooked edible portion for fish. The methods used to cook fish should be those that do not add fat, breading, or seasoning (e.g., salt or spices).

(c) Nutrient data and proposed nutrient values for nutrition labeling for raw fruit, vegetables, and fish may be submitted to the Division of Nutrition (HFF–260), Center for Food Safety and Applied Nutrition, Food and Drug Administration, 200 C St. SW., Washington, DC 20204, for review and evaluation. The data and nutrient values for nutrition labeling are appropriate for use if they are accepted by the Food and Drug Administration (FDA). The submission to FDA should include information on the source of the data (names of investigators, name of organization, place of analysis, dates of analyses), number of samples, sampling scheme, analytical methods, statistical treatment of the data, and proposed quantitative label declarations. The nutrient values for the nutrition labeling should be determined in accordance with FDA guidance.

(d) Composite data that reflect representative nutrient levels for various varieties, species, cultivars; seasons; and geographic regions may be used to label raw fruit, vegetables, and fish. Alternatively, data that reflect a specific variety, species, cultivar; season; or geographic region may be used to label raw fruit, vegetables, and fish; the nutrition labeling information for such variety, etc., should provide food names and descriptions for the fruit, vegetables, and fish that appropriately reflect the samples analyzed for nutrient values.

(e) The FDA manual "Compliance Procedures for Nutrition Labeling" (or subsequent revisions of this manual) should be used to develop nutrition label values from data base values. The manual is available from the Division of Nutrition.

(f) If the agency's Center for Food Safety and Applied Nutrition agrees to all aspects of a submitted data base, FDA will notify a submitter in writing of its acceptance of the nutrient data and nutrient values for nutrition labeling. FDA's acceptance will be for a period of 10 years or until other data for the same food are submitted to FDA and found to be superior. Those obtaining data base and nutrient value acceptance from FDA are responsible for continued maintenance of the data base. FDA will renew its acceptance of a data base upon request after 10 years unless the data have been superseded by other data on the same food or there have been demonstrated changes in agricultural or industry practices. When agricultural or industry practices change (e.g., a change occurs in a predominant variety produced), or when FDA monitoring suggests that the data base or nutrient values are no longer representative of the item sold in this country, FDA will take steps to revoke its acceptance of the data base and nutrient values. A revised data base and proposed nutrient values may be submitted to FDA for acceptance.

(g) If the nutrition information is in accordance with an FDA-accepted data base, the nutrient values have been computed following FDA guidelines, and the food has been handled in accordance with current good manufacturing practices to prevent nutrient loss, a nutrition label will not be subject to the agency compliance review under § 101.9(e).

(h) Organizations may use data bases that they believe validly reflect the nutrient content of raw fruit, vegetables, and fish; however, labeling computed from data bases not reviewed, evaluated, and accepted by the agency is subject to the compliance procedures of § 101.9(e).

(i) FDA will publish, and provide an opportunity for comment on, updates of the nutrition labeling data for the 20 most frequently consumed raw fruit, vegetables, and fish (or a notice that the data sets have not changed from the previous publication) at least every 2 years in the **Federal Register**. FDA accepted data for other raw fruit, vegetables, and fish, or for other nutrients, are available from the Division of Nutrition, Center for Food Safety and Applied Nutrition, 200 C St. SW., Washington, DC 20204.

Dated: November 4, 1991.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Rev 1-91

The authentic text behind the news . . .

The Weekly Compilation of **Presidential Documents**

Administration of George Bush

This unique service provides up-to-date information on Presidential policies and announcements. It contains the full text of the President's public speeches, statements, messages to Congress, news conferences, personnel appointments and nominations, and other Presidential materials released by the White House.

The Weekly Compilation carries a Monday dateline and covers materials released during the preceding week. Each issue contains an Index of Contents and a Cumulative Index to Prior Issues.

Separate indexes are published periodically. Other features include lists of acts approved by the President, nominations submitted to the Senate, a checklist of White House press releases, and a digest of other Presidential activities and White House announcements.

Published by the Office of the Federal Register, National Archives and Records Administration.

The Federal Register

Regulations appear as agency documents which are published daily in the **Federal Register** and codified annually in the **Code of Federal Regulations**

The **Federal Register,** published daily, is the official publication for notifying the public of proposed and final regulations. It is the tool for you to use to participate in the rulemaking process by commenting on the proposed regulations. And it keeps you up to date on the Federal regulations currently in effect.

Mailed monthly as part of a **Federal Register** subscription are: the LSA (List of CFR Sections Affected) which leads users of the **Code of Federal Regulations** to amendatory actions published in the daily **Federal Register;** and the cumulative **Federal Register Index.**

The **Code of Federal Regulations** (CFR) comprising approximately 196 volumes contains the annual codification of the final regulations printed in the **Federal Register.** Each of the 50 titles is updated annually.

Individual copies are separately priced. A price list of current **CFR** volumes appears both in the **Federal Register** each Monday and the monthly **LSA** (List of **CFR** Sections Affected). Price inquiries may be made to the Superintendent of Documents, or the Office of the Federal Register.

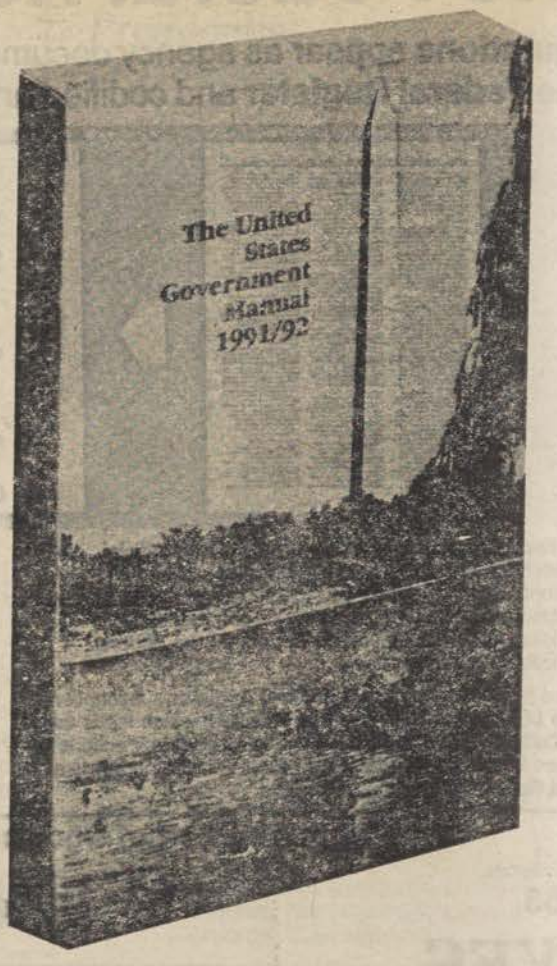
The United States Government Manual 1991/92



As the official handbook of the Federal Government, the *Manual* is the best source of information on the activities, functions, organization, and principal officials of the agencies of the legislative, judicial, and executive branches. It also includes information on quasi-official agencies and international organizations in which the United States participates.

Particularly helpful for those interested in where to go and who to see about a subject of particular concern is each agency's "Sources of Information" section, which provides addresses and telephone numbers for use in obtaining specifics on consumer activities, contracts and grants, employment, publications and films, and many other areas of citizen interest. The *Manual* also includes comprehensive name and agency/subject indexes.

Of significant historical interest is Appendix C, which lists the agencies and functions of the Federal Government abolished, transferred, or changed in name subsequent to March 4, 1933.

The *Manual* is published by the Office of the Federal Register, National Archives and Records Administration.
